In trying to impress these truths on the people of the second city of the Empire, as they are proud to call themselves, we have of set purpose refrained from saying one word about cleanliness and ventilation and limewashing of houses and removal of nuisances and so forth. All these things are excellent, but to prate of them at present might be seriously misleading. It might be thought to mean that there is more than one way of stopping the small-pox which prevails in Glasgow. Cleanliness is good, but it will not stop this epidemic; so is lime-washing, but it will be equally futile for the purpose in hand. By all means ventilate and wash and remove rubbish and filth wherever found; but whether these things are attended to or not, at least make sure of vaccination, and if Glasgow carries out thoroughly this last duty immediately it will have all the rest of the year, undisturbed by small-pox, to attend to other points, while it will be free to enjoy itself over the glories of what is intended to be a great world's fair, but which the great world will certainly shun if small-pox continues to prevail. Later Glasgow may well consider whether vaccinal protection of its adult population from small-pox should not be carried on regularly when the time of life arrives at which every youth should be revaccinated and whether some steps should not be taken to see that the primary vaccination of infants is done thoroughly as well as systematically. These are questions for the national legislature, but Glasgow has its own share of representation and has never been backward in giving voice to its own demands or even to the needs of Scotland which in this respect are identical with its own.

[1] THE LANCET, Nov. 20th (p. 1341) and 27th (p. 1407), and Dec. 4th (p. 1475), 1897.

The Metropolitan Authorities, the Local Government Board, and the Water Companies.

THE metropolitan water companies have withdrawn the regulations in regard to water fittings for which they wished to obtain the sanction of the Local Government Board. The regulations ought never to have been proposed by the companies. When they were submitted to the President of the Local Government Board he should have declined to sanction them. No public inquiry concerning them was needed. The inquiry has caused great expense to the London water consumers. Mr. LONG acted thoughtlessly in respect of the interests of the people of London, for he appointed the Water Examiner, an official whose duty it is to safeguard the interests of the water consumers and to note and report upon the delinquencies of the water companies, to conduct the inquiry. In consequence of the loss of the officer who was their natural protector the representatives of the Corporation of London, of the London County Council, and of the metropolitan boroughs were practically compelled to employ counsel to look after their interests in the inquiry. We fear that Mr. LONG does not even yet appreciate the hardship which he has inflicted on the people of London, for in answer to a question asked in the House of Commons he said that the regulations proposed by the water companies were the practical outcome of the recommendations of Lord LLANDAFF'S Commission, and that therefore the metropolitan boroughs and the other bodies which opposed the regulations ought rightly to pay the expenses which they had incurred in that opposition. We do not think that the people of London will agree with Mr. LONG in this contention, and the fact that all the representative bodies interested were at one in opposing the regulations will, it may be hoped, suffice to show that

although Londoners are a patient people there are limits to the measure of their endurance.

The election of the new members of the London County Council has fortunately occurred at the present juncture and there is no occasion to regret the turn which affairs have taken. The Moderate party have met the fate which they deserved and have been thoroughly beaten. The fact that candidates at the last moment changed the name of the party from "Moderate" to "Conservative and Unionist" has certainly been of no service to them. Electors are not so foolish as to suppose that a change of name means a change of nature. Party politics have no connexion with municipal government. In their policy in regard to water-supply the Moderate party have unfortunately been dominated by some members of the London Municipal Society who have a very close connexion with the business of the metropolitan water companies. This fact has probably not been without effect in deciding the casting of many votes at the late elections. The Progressive party of the Council have now such a large majority that they will have no difficulty in passing any measures which seem good to them. We hope that their power will be wisely used. In the past the Council have failed to be of service in matters concerning water-supply. They have not used the means of control which they possessed over the metropolitan water companies, but they have spent, and not always wisely, large sums of money on agents and surveyors. The expenditure has produced a large quantity of printed matter. The water consumers, however, unfortunately have not been benefited; they have, indeed, been out of pocket by these transactions. It has been conclusively shown that the scheme propounded by the Council for the compulsory purchase of the metropolitan water companies' undertakings could not be advantageously carried out in the interests of the purchasers. It is to be hoped that the Council will waste no more of the ratepayers' money this year in useless or harmful Parliamentary proceedings.

The metropolitan boroughs are to be congratulated on the part which they played in causing the water companies to withdraw their proposed regulations. We egret the expense to which they were put by Mr. LONG'S action in the matter, but, on the whole, we hope that much good will result from the fact that thus early in the history of the boroughs their representatives have had their attention forcibly called to one of their most important duties. To the metropolitan borough councils we chiefly look for the initiation of improvements in the water-supply. Up to the present time the county councils and the vestries have failed to exercise due supervision over the water companies. We confidently trust that the interests of the water consumers will in future be more carefully guarded, and in order that this may be done it will be well for the councils to encourage the burgesses to appeal to their engineers in all cases of difficulty. As a rule, the people of London, and especially the poor, have wished to be interfered with as little as possible in their domestic arrangements, but when they find that help is to be had they will readily avail themselves of it. Up to the present time it has never been tendered to them.

The boroughs will, we hope, obtain and record the important facts in regard to the water-supply in the districts over which they exercise control. Amongst the questions which will require attention it may perhaps not be out of place to suggest some which are of interest:—

1. Has every house a constant water service, and is the pressure at which water is supplied sufficiently high to ensure a supply for the upper storeys of the house?

2. Has the water been efficiently filtered? A daily examination at least of the colour of the water should be made in the case of each company which gives a supply in the borough. Should the water be turbid or of brownish colour a complete chemical examination should be made.

3. A plan should be made of the mains of the water company and their depth below the surface of the ground should be ascertained. Should any of the mains be placed at an insufficient depth notice should be given to the company, so that in case of frost the company should be liable for damage if through their default in so improperly laying the main the water should fail.

4. In the case of excavation in the streets a note should be taken as to the condition of all the mains thereby exposed. It is believed by some engineers that more water is wasted by escaping from the mains of the companies than is lost by defective fittings in private houses. Definite information on this matter would be of great value.

Annotations.

"Ne quid nimis."

MEDICAL AND SURGICAL AID FOR SICK AND WOUNDED OFFICERS.

THE first report of the Duke of Abercorn's Committee, dealing with the work done during the year 1900, was presented for adoption and duly adopted at Hampden House, Green-street, W., on Wednesday, March 6th. The indisposition of the Duke of Abercorn prevented his attendance, and Mr. P. Lyttelton Gell presided and moved the adoption of the report. The report commences by recapitulating the statements contained in the Duke of Abercorn's letter which appeared in THE LANCET of Jan. 13th, 1900, p. 133. It goes on to state that so far back November, 1899, offers of hospitality and of medical assistance reached the War Office not only from the United Kingdom, but also from Madeira, France, Belgium, Italy, Switzerland, Germany, Austria, and Egypt. Many leading consulting physicians and surgeons offered to place their professional skill at the disposal of invalided officers if they were recommended by some accredited authority. To render such generosity available the committee was formed by the Duke of Abercorn and was inaugurated at Hampden House on Jan. 22nd, 1900. The consideration of the conditions upon which the assistance of the professional members of the general committee might be rendered was referred to a sub-committee consisting of Sir Thomas Smith, F.R.C.S. Eng., acting as chairman, Sir Thomas Barlow, M.D. Lond., Mr. Christopher Heath, F.R.C.S. Eng., Mr. Edmund Owen, F.R.C.S. Eng., Surgeon-General J. B. Hamilton, and Dr. Dawson Williams. This committee drew up a report according to which the following regulations were adopted at a meeting held on Feb. 7th, 1900:—

1. Certain physicians and surgeons have definitely agreed to give their services to invalided officers without remuneration, but medical men in general practice who may be in frequent attendance on the clients of the committee will be remunerated at customary rates.
2. Chloroformists and assistants at operations shall be paid the usual fees.
3. All applications for help in connexion with this fund shall be made through the Executive Committee.
4. The Executive Committee shall decide to what nursing-home or

private house each patient is to go, and who shall be invited to attend him.

5. Patients shall be allotted to surgeons or physicians on the General Committee, as far as practicable, in rotation.

6. The Executive Committee shall notify to patients when they are fit to be discharged, either on the recommendation of the medical or surgical attendant, or at the request of the householder.

7. Operations shall, if possible, be performed in nursing homes rather than in private houses.

8. The Executive Committee shall decide where convalescents shall go.

9. The services of electricians, rubbers, and nurses, if recommended by the medical man in attendance, shall be paid for at the discretion of the Executive Committee.

10. The cost of instruments and apparatus recommended by the surgeon in attendance shall be met by the Executive Committee in cases where such assistance appears to them to be necessary.

11. These regulations are subject to revision from time to time as experience of the working of the system is gained.

The Executive Committee was constituted as follows:—The Duke of Abercorn, K.G. (President), Mr. P. Lyttelton Gell, Surgeon-General J. B. Hamilton, Dr. Donald W. C. Hood, Mr. F. A. Johnston, Mr. J. H. Morgan, Colonel J. Stacpole, Colonel on the Staff, and Lieutenant-Colonel H. Charlesworth, R.A.M.C., representing the committee at Southampton; and the Hon. Arthur Brodrick, honorary secretary and treasurer. The duty of making preliminary inquiries into the condition of every applicant was undertaken by Dr. Donald Hood and Mr. J. H. Morgan, and their places were filled during August and September by Dr. Henry John Davis and Mr. T. H. Kellock. Hampden House was on the invitation of the President made the headquarters of the fund, and office accommodation, clerks, and the like were supplied by the British South Africa Company. The Executive Committee desire to pay a warm tribute to the unremitting devotion of Mr. Brodrick. Over 250 cases were considered and of these nearly all received assistance. Of these about 100 were medical cases and 120 surgical, while the remainder were chiefly convalescents. The majority of the medical cases reported upon by Dr. Hood were cases of enteric fever, dysentery, or chronic rheumatism. Except a few who are still under observation, these patients have been satisfactorily restored to health. Of the 120 surgical cases reported upon by Mr. Morgan 39 were operated upon in nursing-homes by surgeons on the General Committee, and the x rays, used under the direction of Mr. Mackenzie Davidson, were found to be of the greatest service. A large number of patients were treated by massage and electricity, while three officers were supplied with artificial limbs under Mr. Morgan's personal direction. There were only two deaths among the whole number of the committee's patients and of these two one was due to incurable disease unconnected with the present war. In addition to officers of the regular army, officers of the Royal Marines, the Imperial Yeomanry, and the colonial forces have also been benefited by the fund. A few of these applications came from officers serving in China or in West Africa. No applications were received from officers of the Royal Navy or from volunteers, though it should be understood that all the advantages of the fund were equally open to officers of these services. Many officers received treatment without applying to the fund through the inexhaustible kindness of members of the medical profession and the hospitality of private persons. The Executive Committee tried to carry out the principle of contributing only towards the exceptional expenses incurred exceeding those which an officer would be unable to defray under the ordinary circumstances of his position. But while pursuing this principle the committee were conscious that many cases might exist in which, though the sufferers were eminently entitled to assistance, yet they might be unwilling to apply. In dealing with such cases the committee were constantly aided by the tactful coöperation of Georgina Countess of Dudley. The generous hospitality of Mr. George Donaldson and of Mrs. Wagg at Brighton and of Mr. George Bullogh in the Island of Rum is acknowledged with special gratitude. The report was seconded by the Commander-in-Chief, F.M. Earl Roberts, in a brief speech, and adopted without a dissentient voice. It tells a tale of most valuable work excellently done.

THE BENNETT CASE.

JUDGMENT has been done in the case of one of the most calculating and cold-blooded murderers on record who within a week or so will pay the penalty for his crime with his worthless life. The trial was one remarkable in many ways. Besides the passions which it aroused making it necessary that the venue should be changed, besides the details which came out, of the existence of a very curious set of people, the proceedings showed that among a certain section of English journals the old-time regard for truth and honour is at a vanishing point. Nothing could have been more damning than the words of the Lord Chief Justice as to the conduct of such journals. The liberty of the press as of the subject is a thing not lightly to be thrown away, but liberty is not licence. Everyone of those responsible for the shameless misuse of their position should be made to answer for his conduct and to pay for it, either by imprisonment or else by a fine so heavy that the process of catching half-pennies by pandering to the worst passions of human nature should be proved to be not worth the risks attendant on such conduct.

URGENT OPERATIONS IN HOSPITALS.

AN inquest was held on Feb. 7th at the North Cambridgeshire Hospital, Wisbech, by Mr. Coroner Welchman upon the body of Joseph Wallis, a farm hand, who died in the hospital on Feb. 6th. Evidence was given that on Feb. 1st deceased was kicked in the abdomen by a horse. He complained of some pain, but went on with his work for about half an hour, after which he went indoors. Mr. T. H. Hills was called and attended deceased up to Feb. 2nd, on the evening of which day the patient was admitted to the hospital. Dr. C. H. Gunson, the house surgeon, said that on admission there was no discolouration or abrasion, but there was a slight distension on the right side of the abdomen. By the evening of Feb. 5th deceased had become very much worse and an operation had to be performed. Mrs. Wallis was not communicated with with regard to the operation, but she knew of the patient's serious condition. Deceased had agreed to the operation himself. The cook at the hospital, who was deceased's niece, said that she had written to Mrs. Wallis on the evening of Feb. 5th, but she said nothing about an operation. The jury returned a verdict of "Accidental death" and added as a rider, "That in the opinion of the jury the deceased's relatives should have been communicated with before the operation and that in all serious cases in future the relatives ought to be communicated with." At a meeting of the hospital committee held on Feb. 19th the rider was discussed and the committee unanimously resolved that they approved of the steps taken by the medical officers and that they were convinced that to have delayed the operation in order to communicate with the patient's wife would have been culpable on the part of the medical officers and prejudicial to the patient. The committee, while anxious to consult the nearest relatives before an operation, as is invariably done when possible, could not accept the rider but preferred to trust in the judgment of the medical officers. It was also resolved that the resolution, the verdict, and the rider should be forwarded to the Home Secretary in order that he might inquire into the matter with a view to the removal of the rider from the records of the coroner's court. We are glad to see that the hospital committee made such a firm stand, for it is obvious that the rider of the jury if acted upon would in many cases render hospital treatment

useless. Cases are constantly arising where immediate operation offers the only chance of life and where it may be impossible to communicate with the relatives who in the country especially may live miles away and who even if a messenger is sent may be out on his arrival. We can only hope that the Home Secretary will decide that this very foolish rider shall not be allowed to remain on the records of the coroner's court.

THE MINERAL WATERS OF FRANCE.

THE society for promoting the study of the natural mineral waters existing in various parts of France intend during the present year to organise an excursion to visit the health resorts in the south-eastern parts of that country. It is intended to include in the projected tour Evian, Divonne, St. Gervais, Sanatorium d'Hauteville, Aix-les-Bains, Marlioz, Challes, Salins Moutiers, Brides-les-Bains, Allevard, Uriage, La Motte, Vals, and Lamalon. Following the successful precedents of former years the excursion is to have the advantage of the presence of Professor Landouzy, who will at each of the places visited give a brief account of the nature and therapeutic value of the waters found there. The excursion is to take place during the first fortnight in September. We are informed that those of previous years have proved highly satisfactory. English visitors were received with every courtesy, and the holiday was pleasant, instructive, and the reverse of expensive. Particulars of the forthcoming tour may be obtained from Dr. Leonard Williams, 8, York-street, Portman-square, W.

INSANITY IN TWINS.

DR. A. CULLERE, medical superintendent of the asylum at Roche-sur-Yon, has published an interesting account of insanity in twins in the February number of the *Archives de Neurologie* and has given the records of two new cases. He first asks the question, "Is there a special insanity affecting twins?" (*folie gémellaire*), and answers the question as follows. The special predisposition of twins renders both liable to one common form of insanity. The attack is characterised by the three following features: first, simultaneity of the attack and more or less parallelism of the symptoms at the onset; secondly, analogous course and similarity of termination of the malady; and thirdly, the spontaneous origin of the disorder arising from a common organic basis. When these features are present it is possible to recognise in the insanity of twins an origin in degeneracy, for the common basis of development is usually some form of congenital mental debility or even imbecility. The onset of intellectual disorder is often early, it is characterised by variability of mental symptoms (polymorphism), and it has a tendency to pass into premature mental enfeeblement (dementia præcox). Dr. Cullere is inclined to view the very fact of twinship (*gémellité*) as itself an indication of inferiority, and quotes to this effect the experiences of Keim, Fournier, and Jonathan Hutchinson that twins are relatively common in the offspring of tuberculous and syphilitic parents. A strong neuropathic heredity is almost always met with in the genealogical history of insane twins, and this even when but one of the twins is the subject of insanity. Thus in six out of seven such cases the parental taint appeared in the form of phthisis and lithiasis, phthisis and nephritis, insanity of the litigious paranoiac form, moral imbecility, or other nervous defect. The following cases illustrate insanity in twins. Case 1.—The patients were twin sisters, firstborn; the father was alcoholic and of precarious health. The mother was in normal health but bearing a neurotic taint from alcoholic and phthisical grandparents. The twin sisters were backward in speech and intelligence but otherwise enjoyed good health. They menstruated at the age of 16 years. One became a seamstress and the other a domestic servant. At about the age of 17 years both began to show signs of mental confusion, irritability, and violence of temper. Both suffered from terrifying dreams and nightmare. They grew worse and one of them had to be placed in an asylum, the chief symptoms being maniacal excitement and irresistible impulses to violence and murder, which continued with remissions and intermissions for some years. She then became mentally enfeebled. The other sister exhibited similar symptoms of mania and murderous impulses and had intermittent attacks of frenzy mingled with incoherent screaming, cursing, and crying; she made several attempts to dash out her brains. She gradually subsided to a quieter condition after a few years and exhibited a less degree of mental enfeeblement than did her sister. Both sisters exhibited facial asymmetry. Case 2.—The patients were twin brothers, the sons of a hypochondriacal man whose sister was insane. The twins were born at the fifth confinement and were during childhood noted to be weak-minded. Their mental disorder began to develop at about the age of 20 years. Both had a marked propensity to alcoholism; one became a soldier and while on military duty was seized with an attack of mental confusion and excitement. After this he had repeated maniacal attacks, and drinking always brought them on. He then developed delusions of a grandiose nature. The other at the age of 20 years had subacute delirium and passed into a stage of stupor. He subsequently developed delusions of persecution of a persistent kind.

THE VALUE OF SALINE ENEMATA IN COLLAPSE AND IN URÆMIA AND PUERPERAL ECLAMPSIA.

THE great value of saline enemata in a number of conditions, of which the most important are severe hæmorrhage, uræmia, and puerperal convulsions, is not sufficiently appreciated. One reason for this appears to be that intravenous or subcutaneous saline injections are much more recommended by authorities. Why they neglect to enforce the value of the much simpler, far more generally available, and equally efficacious method of rectal injection we cannot imagine, unless it be that its very simplicity has caused them to overlook it. In the emergencies of general practice instruments for intravenous or subcutaneous injection will often be wanting and can be procured only after a loss of valuable time. In an annotation [1] we referred to the value of saline injection in the hæmorrhage of typhoid fever, and *à propos* of this Mr. W. M. Gabriel [2] pointed out the advantage of the less cumbrous method of rectal injection over intravenous. He related the case of a man *in extremis* from repeated intestinal hæmorrhages in typhoid fever. Other means having been exhausted, a pint of hot saline solution was injected into the rectum and had to be retained artificially owing to the atony of the sphincter. After several minutes a faint radial pulse was perceptible and recovery followed. In the *Journal of the American Medical Association* of Feb. 9th Dr. T. B. Greenley has related two cases which show the value of saline enemata in collapse from hæmorrhage. He was called to a woman suffering from hæmorrhage due to abortion at the end of the second month. She was collapsed, pulseless, and very pallid. As soon as he could have it prepared he injected nearly half a gallon of hot salt solution into the bowel and kept it there by pressure on the anus for one and a half hours. The pulse returned and turpentine and ergot were given every two hours. The hæmorrhage ceased and the ovum was expelled. Next day the patient was doing well. In a second case a woman was flooding in the third

[1] THE LANCET, Jan. 14th, 1899, p. 112.
[2] THE LANCET, Jan. 21st, 1899, p. 190.

month of pregnancy; she was nearly pulseless and her heart was beating very feebly. The same treatment was adopted and clots were removed with the fingers from the uterus. She rallied in less than an hour, when the hæmorrhage was completely arrested. In another case a child, aged eight months, was suffering from cholera infantum. For three days there had been vomiting and purging, and food had been kept on the stomach only 10 minutes. The "small vibration" of the pulse at the wrist could not be counted. Nearly a pint of salt solution was injected into the bowel and retained by pressure. In less than an hour the pulse improved. A teaspoonful of milk was then allowed every 15 minutes. The child ceased to vomit and recovered in a few days. Dr. Greenley comments on the astonishing rapidity with which the injection is absorbed when the blood-vessels are empty. He uses salt solution at a temperature of from 110° to 115° F. and of the usual strength (a drachm to the pint). He rightly points out that in such cases transfusion would be attended with greater risk and entail much trouble and that there is no time to send for instruments or further medical assistance. Possibly in extreme cases, as Mr. Thelwall Thomas insists,[3] nothing short of intravenous injection is of use, though we are inclined to think that cases of hæmorrhage in which an intravenous injection would save life and a rectal injection would fail are few if, indeed, any. Moreover, the former operation is often impracticable or, if practicable, involves the loss of invaluable time in preparations, sterilising instruments, &c., which more than counterbalances any possible advantage of intravenous over rectal injection. The *rationale* of this treatment was explained by Dr. William Hunter in his lectures at the Royal College of Surgeons of England in 1889. In fatal hæmorrhage death results because the heart is not supplied with sufficient fluid upon which to contract; saline solution supplies the necessary fluid. This treatment should have precedence of all others, though such may also be adopted. Exactly the same applies to the treatment of uræmia and puerperal eclampsia. In these conditions the all-important indication is to re-establish the renal secretion and not, as is often thought, to endeavour to stop the convulsions by chloroform, bromide, morphia, &c. (That these measures are of some value is not denied.) Now the introduction of saline solution into the circulation is the most trustworthy of all methods of re-establishing the renal secretion and the simplest means of accomplishing this is by saline enemata. In addition barley water or other diluents may be given by the mouth—as drinks if the patients can swallow, by the stomach pump if they cannot. If this rational treatment, which aims at removing the cause of the uræmia or eclampsia, were generally adopted, instead of the mere treatment of symptoms by sedatives, we believe that many valuable lives would be saved.

THE INCREASE IN APPENDICITIS.

IN a discussion at the meeting of the Paris Academy of Medicine on Feb. 19th M. Lucas-Championnière expressed the opinion that appendicitis is rapidly increasing in frequency and he is inclined to attribute this to an increase in the causes of intestinal infection, the chief of which he considers to be the eating of meat in large quantities. In this way he explained the fact that appendicular affections are most common in countries where much meat is eaten, such as England and the United States. The explanation of the increase of appendicitis need not be considered until it has been certainly shown that an increase has occurred. M. Lucas-Championnière thought that if appendicitis had formerly been as frequent as at present the fact would have been noted by observers. This does not necessarily follow, for until appendicitis was recognised to be the lesion present in most cases called "typhlitis" and "perityphlitis" it was hardly ever diagnosed till the post-mortem examination. A large proportion of the cases formerly called "idiopathic peritonitis" must have been cases of appendicitis. That ulceration and perforation of the vermiform appendix might occur was known many years ago—for instance, in 1856 Dr. Lewis, in the *New York Journal of Medicine*, collected 47 cases of perforating ulcer of the appendix—but the name "appendicitis" is of comparatively recent origin. There is, in fact, but little, if any, reason for thinking that a real increase has occurred in the number of cases of inflammation of this process, but the transference of many of these cases to the surgeon and the great increase in recent years of laparotomy for obscure abdominal conditions have led to an apparent increase.

[3] THE LANCET, Nov. 26th, 1898, p. 1390.

THE CHEST PANTOGRAPH.

IN the New York *Medical Review of Reviews* of Jan. 25th there is an illustrated description of an instrument devised by Professor Winfield S. Hall of the North-Western University Medical School, by the use of which he claims that chest-contours can be accurately measured and recorded. It has the usual four jointed arms of a pantograph, but differs from the ordinary pantograph in having attached to it at the angle most remote from the fixed point a brass or steel semicircle which lies altogether outside the parallelogram of the frame and has its diameter in a line with one of the arms forming the angle there. The extremity of the semicircle most remote from the pantograph serves as the tracing-point. The object of the semicircular arm is, of course, to permit the tracing point to be carried round the thorax and the semicircle can, when required, be rotated round its diameter so as to reach both sides of the chest. The seat upon which the patient sits is adjustable for height and has back and side supports for the waist, so that the upper part of the body is not allowed to move from side to side, distorting the contour. The patient sits beside a table on which the fixed point of the pantograph is pivoted in the usual way and the contour is drawn by the writing pencil on paper ruled in squares of one millimetre. Professor Hall places the writing pencil so that the contour drawn is one-fifth of the contour copied, giving a size convenient for reference and preservation. He prefers his instrument to the apparatus devised in Sweden for the same purpose. The diameter of the semicircular arm is 40 inches. The parallelogram is, of course, equilateral; the length of the sides is not stated, but it is apparently about 54 inches.

THE "SAINT-PIERRE."

AT the end of a brief summary of the medical transactions in Newfoundland waters carried out under the auspices of the Société des Œuvres de Mer during the year which has just expired, Dr. Bonnafy makes the welcome announcement that in order to replace their present hospital ship the *Saint-Pierre*, which is a sailing vessel, the authorities of the association have caused a steamer to be constructed with special fittings for medical and surgical work amongst the fleet of French ships engaged in the cod-fishing industry. Although dependent for progression on sails alone the *Saint-Pierre*, which left St. Malo last April in charge of Dr. Bonain of the French naval service, was nevertheless able within the space of six months to complete five cruises embracing the whole of the fishing ground. In the course of these continuous peregrinations, during weather that sometimes was calm but more often "dirty," communication was established with 301 fishing

boats, when all slight cases of sickness or injury among the crews were duly attended to on board their own craft, the more serious cases, 88 in number, being transhipped into the *Saint-Pierre* for treatment. The average duration of each of the latter cases was a fraction under seven days, but the time spent on board by 27 additional patients who were carried back to France at the end of the season is not included in this calculation. In addition to affording medical aid the officials of the hospital ship also undertook post-office duties, delivering 7261 letters among the fishers and receiving 4020 in return for conveyance to families and friends at home. Ten sailors adrift in four dories were picked up and rescued by the *Saint-Pierre* during her cruises. This remarkable fact exhibits in a very sombre light the difficulties and dangers of the life led by the cod-fishers. Every year there are numerous victims, sometimes more and sometimes less, swallowed up by the impenetrable fogs. In the season of 1899 the number saved by the hospital ship was 20; in the previous year it was 10. Among the 115 admissions the chief diseases were as follows: typhoid fever, 15; bronchitis, 14; pulmonary tuberculosis, five; scurvy, seven; nephritis, six; rheumatism, six; pleurisy, three; alcoholic gastritis, two (10 slighter cases were treated on board the patients' own ships); phlegmon, nine; ulcer, 10; fracture and dislocation, seven; *embarras gastrique*, four; wounds, &c., 12; and venereal affection, one.

SYMPTOMS OF CEREBRAL SYPHILIS.

DR. JAS. MACBRIDE draws attention in the *Journal of the American Medical Association* of Feb. 2nd to the fact that in the majority of cases of cerebral syphilis the mental symptoms are largely of a negative kind—e.g., loss of mental power and of self-control, impairment of memory, loss of interest in surroundings, and a liability to undue emotional disturbances such as anger and crying. Attacks of loss of speech or of sight ("blind spells") occur not uncommonly at an early stage and demand careful diagnosis, as an error may be serious. Thus one patient suffered from "blind spells" which had been erroneously diagnosed and treated as biliousness until it was found that they were due to cerebral syphilis. Delusions, if present in an early stage, are incongruous and of quickly-changing character, and never deeply affecting belief or conduct. There is general confusion of mind. Drinking and drug habits are prone to be indulged in at this stage, the patient seeking a narcotic or anodyne to relieve his mental distress. The lapsing into such habits at this stage also betokens a loss of mental balance and self-control. Mental disorder may appear in the syphilitic subject very soon after the appearance of secondary symptoms; one such case has been recorded where it developed within three months of infection, and in a case observed by Dr. MacBride the interval was six months. It is found that syphilitic inebriates are particularly liable to commit suicide after a drinking bout. Syphilitic insanity sometimes closely resembles general paralysis, but has more frequent focal symptoms—e.g., paralysis of one or more cranial nerves, local cerebral hæmorrhages or softenings with Jacksonian convulsions, and sometimes recovery may result, though in true general paralysis recovery probably never takes place. Charcot long ago called attention to a characteristic of syphilitic brain disease—viz., irregular and temporary attacks of aphasia, a condition which is correlated with atheroma and disease of the cerebral arteries. In one case noted by Dr. MacBride when the patient took a long walk or played tennis he had transient spasm in the right arm and leg followed by temporary paralysis. "If he talked for any length of time he developed a temporary ataxic aphasia, showing what little reserve power was left to the brain as the blood-stream was gradually shut down" by atheroma. In syphilitic meningitis there was always cortical arteritis. According to its location there were symptoms of headaches, neuralgias, and oculo-motor and other palsies of cranial nerves. The mental symptoms varied from stupor to active delirium and furious violence. Gummata produced local symptoms, and while predisposition had much to do with determining a special encephalopathy following syphilis, yet it was probable that a special virulence of the syphilitic virus was sometimes the cause, as in the case mentioned by a French writer of a woman who infected five youths with syphilis, with the result that three of them died from general paralysis, while two suffered from cerebral syphilis. Syphilis of the brain occurring after 10 years from the date of infection was rare. M. Fournier mentioned a patient who was entirely well for 17 years after syphilitic infection and then died from cerebral syphilis.

THE FIFTH TRIENNIAL INTERNATIONAL CONGRESS OF PHYSIOLOGISTS.

THE fifth Triennial International Congress of Physiologists will be held at Turin this year from Sept. 17th to 23rd. The University Institute of Physiology, under the direction of Professor Angelo Mosso, will be placed at the disposal of the Congress. In connexion with the Congress an exhibition of apparatus will be open from Sept. 14th to 23rd; to it the Marine Biology Station of Naples will contribute a collection of marine forms of animal life useful for comparative physiology. Those desirous of contributing to the work of the Congress should communicate with Professor Sherrington, general secretary for the English-speaking countries, Thompson-Yates Laboratories, the University College, Liverpool.

EPILEPTOID TREMBLING: A SYMPTOM IN PULMONARY TUBERCULOSIS.

IN the *Revue Neurologique* of Jan. 15th an interesting communication upon this new and little known clinical sign of "epileptoid trembling" in pulmonary tuberculosis appears from the pens of M. Léopold Lévi and M. Follet. Epileptoid trembling as a symptom observable in phthisis is far from being exceptional; it is now known to clinical observers, though no mention is made of it in the text-books of medicine. Out of 50 cases this symptom was ascertained to be present in nine instances. The following is a typical case. A young woman, aged 22 years, suffered from pulmonary tuberculosis and had a cavity in the apex of the right lung. When she put her foot on the ground a jerky spasm of the flexors of the ankle came on and was followed by clonic movements if pressure against the ball of the foot was maintained. Ankle clonus and patellar clonus were easily elicited. There was no local muscular atrophy and cutaneous sensibility was everywhere normal. Her occupation was that of a compositor, but she seemed quite free from symptoms of lead-poisoning. She was free from symptoms of hysteria and of epilepsy, but had suffered from attacks of indigestion, with headache, disturbances of vision, nausea, and epigastric discomfort. The visual disturbances occasionally took the form of hemiopia. A second case was similar to the above. Of the seven other cases two were males and five were females, the ages varying from 18 to 30 years. Three of the latter had a previous history of typhoid fever, while another was at one time addicted to absinthe-drinking and appeared to be an unstable, emotional, neurotic person, subject to cramps of the great toe and vaso-motor troubles of the feet. The fifth was nervous and was occasionally subject to hysterical fits. M. Lévi and M. Follet point out that none of their cases suffered from paresis, amyotrophy, trembling, or myoidema. It was not possible to elicit the reaction of debility or of cachexia in the muscles. The

existence of pulmonary cavities in all the cases in which the symptoms of epileptoid clonic trembling were observed suggests the question whether such symptoms were due to the action on the spinal cord of toxins produced by the micro-organisms in the lungs. M. Lévi and M. Follet do not believe that the symptoms belong to the class of phenomena known as idio-muscular contraction. While admitting that "epileptoid trembling" indicates a condition of excitation of the pyramidal tracts which, however, does not result in degeneration of the nerve fibres, they incline to the belief that the trembling is due to the action of toxins of tuberculous or para-tuberculous origin. The symptoms, in short, indicate the presence of the "mixed infection" which supervenes in the progress of pulmonary tuberculosis.

ENDOWMENT OF A LECTURESHIP AT GUY'S HOSPITAL.

IT was announced a few months ago that a generous donor had presented to the governors of Guy's Hospital the sum of £6000, the interest of which was to be used for the purpose of medical education and research. The question of the best means of utilising the benefaction was referred to the staff of the medical school and with the approval of the donor it has been decided to endow a lectureship in experimental pathology. The holder of the appointment will be known as the Gordon lecturer, to commemorate the fact that the endowment is due to the generosity of Mr. Robert Gordon. It will be a matter for general satisfaction that so important an addition has been made to the extremely small number of endowed lectureships in connexion with medical education in London. It is particularly appropriate that this addition should have been made at the moment when the metropolitan medical schools have become affiliated to the University of London. It is confidently hoped that the reconstitution of the University may do much to improve medical education in London, but without money substantial reforms are with difficulty carried out. If Mr. Gordon's example is followed by other wealthy men who appreciate the great benefit to mankind of the increase and dissemination of medical knowledge, the Faculty of Medicine of the University of London will approach its labours in the cause of reform with a light heart.

COLORIMETRY IN WATER ANALYSIS.

THERE is little doubt that with greater attention to colorimetry this convenient method of diagnosing the quality of water for drinking purposes will become more accurate and reliable. The colour of water itself is some indication of its purity and origin while the approximate determination of the degree of turbidity is valuable in the same direction. The value of observations on colour and turbidity depends largely upon the standards adopted. The standards must of course be unvarying and uniform. It may be noticed that in the monthly reports of the chemists to the London water companies the colour of the water is recorded in degrees of brown and blue based respectively upon solutions of standard bichromate of potassium and copper sulphate. Both these salts are permanent and are therefore very convenient and accurate for the purpose. Blue, of course, is the normal colour of pure water, the degree of brown indicating more or less organic matter. It has been shown that the degree of brown varies directly with the proportion of organic carbon in water. In America the determination of the yellowish-brown colour of water has been based upon a standard of Nesslerised ammonia. But better than this standard is that obtained by mixing solutions of a definite strength of potassium platinic chloride and cobaltous chloride. This standard appears to be perfectly uniform and practical and accurate for the determination of the colour in water. It is known as Hazen's platinum cobalt standard. As regards turbidity, permanent standards are made containing a weighed amount of kaolin to distilled water. Permanent standards may be obtained in the case of determining the nitrogen in nitrates in water without recourse to artificial colours; for the production of a yellow colour by the action of nitric acid upon phenol, as is depended upon in the analysis of water, is quite permanent. Permanent ammonia standards for both free and albuminoid forms may be prepared with the cobalt platinum solution already mentioned. In the case of the estimation of nitrites depending upon the production of a pink colour with sulphanilic acid and naphthylamine hydrochlorate, this may be matched perfectly with a cobalt copper solution. In the same way the iron in waters, converted into the ferric form by suitable means, may be exactly measured by means of a mixture of standard platinum and cobalt solution. The permanency of a standard solution is an immense advantage and all contributions to our knowledge relating to these factors in analysis will be welcomed. The latest contribution, upon which some of the above statements are founded, is from the Mount Prospect Laboratory in Brooklyn, New York, by Mr. Daniel E. Jackson, and his observations will be read with interest by all those concerned in the analysis of potable water.

MASQUERADING AS A MAN.

ON March 2nd a person described on the charge-sheet as "Catherine Coome, aged 66, house decorator, of no fixed home," appeared in connexion with a case of alleged fraud. She appeared in court dressed as a man and, according to her own story, she was married at 15 years of age. Having served as a schoolmistress she went to Birmingham where she determined to personate a man, as she thought she would get on better. She served for two years on board of a Peninsular and Oriental liner as ship's cook and became acquainted with the maid of a lady who lived at Hampton Court. This maid she "married" and they lived together for 14 years. The "husband" then returned to London, where, on account of meeting with severe injuries, she had to enter the workhouse, where her sex was discovered. The story is strange enough, but there is nothing particularly new about it. Besides such heroes of romance as Billy Taylor, the immortal Rosalind, and the love-sick crew who (according to Mr. Gilbert) shipped with Lieutenant Belay, there are historical instances of women who have passed their lives as men. Such a one was Christina Davis, who died in July, 1739, after having served many years in the 2nd Dragoons, afterwards the Scots Greys. She was born in 1667, and when quite a young woman married a man named Welsh. One day Welsh was forcibly recruited and sent to serve in Holland in Lord Orrery's regiment. Christina thereupon dressed herself as a man and enlisted as a foot soldier so as to find her husband. After many adventures, during which she served in the battle of Landen, was wounded, taken prisoner, exchanged, and fallen in love with, on account of which last affair she had to fight a duel, she enlisted in the cavalry and was present at the siege of Namur. After the peace of Ryswick she returned to Ireland without having found her husband, but on war being again declared she took up service again. After the battle of Blenheim she was on prisoners' guard and there met her husband, who had long thought her to be dead. They decided to pass as brothers and continued to serve. At Ramillies she was severely wounded and her sex was discovered. Her husband was killed at Malplaquet, but she was twice married afterwards. At her death she was buried in the grounds of Chelsea Hospital with military honours. Two other remarkable women were Anne Bonney and Mary Read, who lived about 200

years ago and carried on a successful career as pirates, but the classical instance of a woman passing as a man is that of James Barry, M.D., of the Army Medical Staff, a full account of whose remarkable career was incorporated into a novel, "A Modern Sphinx," by Lieutenant-Colonel Rogers.[1] The sexual problems involved in such cases form a curious chapter in medical psychology.

MEDICAL MEMBERS OF THE LONDON COUNTY COUNCIL.

THE following medical men are among the members of the newly-elected County Council of London: Dr. W. J. Collins (St. Pancras, W.), Mr. G. J. Cooper (Southwark, Bermondsey), Dr. G. B. Longstaff (Wandsworth), and Dr. J. F. Little (Marylebone, E.). With the exception of Dr. Little, who gained his seat by one vote, all these gentlemen were members of the last council. Among the members of the profession who unfortunately failed to secure a seat on the council was Dr. E. B. Forman who offered himself for re-election.

FARQUHAR, NORTH, AND CO. *v.* LLOYD.

IN commenting upon this case in an annotation in our issue of Dec. 1st, 1900, we expressed the view that the damages awarded by the jury were excessive, even assuming that the article complained of which appeared in the *Daily Chronicle* exceeded the limits of fair comment upon the proceedings in the county-court. It may be remembered that the plaintiffs were manufacturers of tinned provisions and had sold goods to a tradesman who had refused to pay for them, contending that they were defective and that had he sold them they would have proved dangerous to the public. The defective condition of the goods was admitted, but the *Daily Chronicle* appears to have erred in its criticism by implying, in accordance with the view of the jury, that the stock of the plaintiffs' beyond those articles sold to the retailer in the case would be found in an equally defective and dangerous condition. For ourselves we maintain that the press does the public an eminent service by its honest criticism and, if need be, censure. This particular case is one which concerns us as medical journalists, for we are constantly dealing critically with foods and proprietary preparations, and if we found poisonous material in a food or a food dangerous to health we should not hesitate to say so. But in thus performing a public duty it is of course most desirable to restrict all censure to the real facts of the case and to keep it free from the smallest external implication. This the *Daily Chronicle* did not do. All the same, the damages awarded were very excessive, but we are glad to find that on contesting the award of £1900 in the Court of Appeal this week the proprietors of the *Daily Chronicle* were allowed a new trial. The Master of the Rolls said that only a very gross libel could command such excessive damages. The verdict, he added, was a scandal, and there must be a new trial unless the parties would agree that the damages should be reduced to £500. The ultimate issue will be interesting.

LOCAL AUTHORITIES AND THE COST OF CONVERTING CONSERVANCY TO WATER-CARRIAGE SYSTEMS.

DR. MEREDITH YOUNG, the medical officer of health of Stockport, raises some pertinent points in a paper in the January number of the *Sanitary Inspector* in regard to the position of local authorities in embarking on large schemes in connexion with the conversion of conservancy systems to water-carriage systems. As is well known, a number of towns have within the past few years obtained Parliamentary powers to contribute towards the cost of converting privy middens into water-closets. While from one point of view this step, as he points out, is commendatory, it may be, perhaps, scarcely equitable from the standpoint of the general ratepayer. In considering the cases of some large Midland towns he shows that the assumption that the results are in favour of local bodies contributing towards the work of conversion in a wholesale manner is hardly justified when certain points in the information are emphasised. Rather it is evident that care should be exercised in taking advantage of the clauses of a private Act or the general body of ratepayers may have to bear the whole of the cost of transforming foul and dilapidated privies into efficient water-closets. In the same number of the journal referred to Mr. C. W. Laskey, the chief sanitary inspector of Eccles, contributes a paper on the same question in which he points out that, owing to the late Lord Chief Justice's decision, magistrates have now no power to order the conversion of an existing privy into a water-closet under the Nuisances Clauses of the 1875 Act, and that local authorities must either have recourse to section 36 or else obtain a private Act of Parliament.

THE annual clinical debate of the Chelsea Clinical Society will be held at the Jenner Institute of Preventive Medicine on March 12th and 19th. The subject for debate is "The Clinical and Pathological Relations of the Chronic Rheumatic and Rheumatoid Affections to Acute Infective Rheumatism." The debate will be opened by Dr. Archibald Garrod, and the following gentlemen will speak, amongst others, on March 12th, Dr. F. J. Poynton, Dr. Alexander Paine, Dr. G. A. Bannatyne, Mr. N. C. Macnamara, and Dr. C. O. Hawthorne. The meeting will be held at 8.30 P.M.

THE Brussels Medical Graduates' Association have unanimously resolved to send an address to the King which sets forth that the members of the association humbly desire to offer their respectful sympathy to His Majesty in his recent bereavement, "caused by the death of our late Sovereign Lady Queen Victoria." The address further congratulates the King on his accession and prays that he may long occupy that exalted position and may worthily extend the beneficence of that rule "so happily inaugurated by her late Majesty."

IT is announced that the honorary degree of LL.D. is about to be conferred by the University of Edinburgh upon Sir John Williams, Bart., M.D., F.R.C.P. Lond.; upon Dr. James Little, Regius Professor of Physic in the University of Dublin; and upon Sir Robert Bannatyne Finlay, the Attorney-General. Sir Robert Finlay, who has attained such great distinction in the faculty of law, began his career as a medical man and graduated as M.D. at the University of Edinburgh. He is also a Fellow of the Royal College of Physicians of Edinburgh.

A TELEGRAM from the Governor of Cape Colony, Sir Alfred Milner, to Mr. Chamberlain, received at the Colonial Office on Feb. 27th, states that the bubonic plague report for the week ending Feb. 23rd was as follows: There were 29 cases remaining under treatment at the end of the week, seven deaths have occurred since the commencement of the outbreak, and there are 21 cases remaining under treatment and 167 "contacts."

WE regret to hear that the Lord Chief Justice is so unwell as to be obliged to cease work temporarily, though we are glad to learn that he is not likely to be much longer confined to his bed. There is no doubt that Lord Alverstone's illness had its origin in the atmosphere of the Central Criminal Court where he presided for six days over the trial

[1] THE LANCET, Jan. 4th, 1896, p. 82 et seq.

of Bennett. We shall have more to say concerning the condition of this court.

THE St. Patrick's Festival Dinner of the Irish Medical Schools' and Graduates' Association will be held at the Hotel Cecil on Saturday, March 16th (St. Patrick's Day falling this year on Sunday), at 7.15 P.M., the President, Dr. William Alexander, in the chair. Applications for tickets should be made without delay to Dr. J. Hutchinson Swanton, honorary secretary to the Dinner Committee, 40, Harley-street, W.

THE King, as Sovereign Head and Patron of the Order of St. John of Jerusalem in England, has approved the election by the Chapter-General of His Royal Highness the Duke of Cornwall and York, K.G., Sub-Prior of the Order, to the office of Grand Prior, vacant by His Majesty's resignation.

OWING to an epidemic of infectious disease, presumed to be influenza, which is prevailing on board H.M.S. training-ship *Britannia* the cadets were on March 2nd sent home for a period of three weeks.

MR. G LESLIE EASTES, M.B., B.Sc. Lond., who has been Laboratory Director of the Clinical Research Association, Limited, having vacated that post, has opened a laboratory for similar work at 62, Queen Anne-street, W.

HIS MAJESTY THE KING has signified to the President and Council of the Marine Biological Association his pleasure in becoming the patron of the association.

DR. HENRY WARD IRVINE has announced his retirement from the post of consultant to the Birmingham Consultative Medical and Surgical Institution.

THE YESTERDAY AND TO-DAY OF AURAL SURGERY.

BY SIR WILLIAM DALBY, F.R.C.S. ENG., &C.

THE rapidity with which events in any department of surgery crowd upon each other and engross the attention of those who practise our art leaves little time for reflection, but it may not be altogether useless sometimes to pause for a few moments and consider, not only the extraordinary changes which have taken, and are taking, place, but the influence which such changes may be expected to have on the future. After the foundation of the Otological Society of the United Kingdom, which did me the honour of electing me President, the first meeting was held on Feb. 5th, 1900. Subsequently all the meetings were largely attended, the interest never for a moment flagged, and there was more material (all of which was most valuable) than could be presented and discussed. Finally, after the session the Transactions were published.

Not so many years ago it was a prevalent idea amongst surgeons that there was not a great deal of surgery in aural surgery, and that those who practised it were chiefly, if not entirely, engaged in endeavouring to give relief to the symptoms of deafness, tinnitus, and pain in the districts within and around the ear. If any such person is alive at the present moment—and I make no doubt that there are many—let him read those Transactions to which I have referred. He will there find some 30 contributions. Most of the cases were shown, submitted to the careful examination of the members present, and discussed most thoroughly. Anyone who reads these Transactions will find nothing but modern surgery and pathology, and throughout the whole volume hardly a mention (beyond what was incidental to the cases) of deafness or tinnitus. In short, the gravity of the cases in regard to life hardly permitted more than a passing attention to these symptoms. The time of the meetings was chiefly taken up in discussing cases of cerebellar abscess recently operated on, cholesteatoma removed from mastoid and meatus, thrombo-phlebitis of lateral sinus, adeno-sarcoma removed, ossicles removed for long-standing suppuration, complete mastoid operation, papillomatous growths removed, epithelial grafting of the labyrinth after removal of the semi-circular canals, sarcoma of the temporal bone, epithelioma of the meatus, &c.

Surely in this list, which might be enlarged, there was no lack of surgery except that sort of surgery which was supposed to engage the attention (to the exclusion of all else) of the aural surgeon. A not altogether unnatural conclusion to which the reader might arrive is that the aural surgeons were so much engaged in, and so fascinated by, the operative surgery that has been mentioned that they had no time or inclination to bestow to what, after all, the multitude is seeking, the relief of deafness which so interferes with their occupations, their careers, their pleasures, and their happiness. Now this would be an assumption not in accordance with facts. It should be borne in mind that for many years past aural surgeons have been working incessantly and bestowing the most unremitting attention to the pathology of the changes which take place within the middle ear with a view, not only to their remedy, but their arrest and the protection against their advent, in this latter direction, especially in the case of childhood and early life, as our records, our daily practice, and results will show, with remarkable success. Let it be also remembered that nothing but the most laborious attention to details and the most careful watching of minute changes has effected this—so laborious that it has required faith in the possibilities that might follow to sustain the workers. One bit of knowledge (the fruit of experience) must always be present to the mind of the aural surgeon who intends to succeed with his cases, and this is that the most minute variations which are extraordinarily apt to escape the notice of a not very earnest observer make all the difference between bad and good hearing. This applies with especial force to middle-ear troubles, but in a measure also to nervous ones.

The surgery which our Transactions have displayed is no doubt very attractive. It is conceivable then, I repeat, that the reader might be led to think it possible that the more work a surgeon of this sort gets the less inclined he may be to trouble himself about the more wearisome and oftentimes disappointing though numerous cases in which the results are not so striking and life-saving. As one who has borne the burden and heat of the day I may be forgiven for assuming for the moment the position of the reader who asks this question and for sounding a note, not of warning, but rather of suggestion, to those who may be thinking of adopting a speciality the advancement of which has been the chief object of my life for some years. If it were necessary to do so I could point out endless examples in which nothing but the expenditure of a great deal of labour can teach the observer the best treatment of minor troubles and give him the delicacy in manipulation that is so necessary and so appreciated by the patient. Again, notwithstanding all the failures that have attended intra-tympanic operations preceded by incision of the membrane for the relief of obstruction within the tympanic cavity; notwithstanding that at some periods incision of the membrane was largely practised, at others given up (except in acute cases to let out pus), only to be revived again and again discontinued, the problem of relieving labyrinthine pressure will, I believe, some day be solved. Those who share this view with me will gain a ray of hope on reading in the Transactions a case by Mr. C. A. Ballance in which, when removing portions of dead bone from the petrous bone, "the semicircular canals were in part destroyed and the back of the vestibule opened." Later, after epithelial grafting operation, the hearing, which had been absent since childhood (there had been otorrhœa and mastoid disease), returned.

Whilst, therefore, I cannot but think that the reading of our Transactions will be a revelation to some as to the work which has been done, and so interesting a revelation that I venture to recommend their perusal, I should much regret if an impression should arise that any part of the province of aural surgeons was in danger of being neglected by our members, so I have anticipated the possible suggestion that may arise in order to combat it and dismiss it as untenable.

HISTORY OF RENAL SURGERY.

BY DAVID NEWMAN, M.D., F.F.P.S. GLASG.,
SURGEON TO THE GLASGOW ROYAL INFIRMARY.

II.[1]

NEPHROTOMY FOR RENAL CALCULUS AND FOR SEPTIC DISEASE.

IT is in the writings of the ancient Arabians that we first meet with a distinct indication that a desire occupied the mind of the surgeon to incise the kidney for the evacuation of an abscess or the removal of a stone. In the eleventh century Avicenna[2] (A.D. 1037) along with Rhases (A.D. 850) and Serapion (ninth century) had taken a distinct step backwards, and he recommended for bleeding from the kidney to inject the rennet of a hare. Avicenna, however, did not take a favourable view of incision for stone in the kidney. He states as follows: "Sunt qui laborant extrahere (calculum renalem) per incisionem ilii et per dorsum"; which he characterised as "Operatio ejus qui rationem non habet." Severe though this judgment may appear to be, it is still clear from Avicenna's words there is reason to believe that cutting the kidney was practised in his time, for without the practice having been employed the judgment above quoted would not have been given. Charles Bernard[3] says:—

> But from Avicen's words there is some colour to believe it was practised in his days, though undoubtedly if it were, from him talking so slightly of it it was only by persons of mean character, such, perhaps, as our mountebanks, who having no regard or concern for the lives of men and little reputation of their own to lose venture boldly and sometimes successfully upon those things which wary and more judicious men avoid.

And Turner (page 429) says of Avicenna:—

> There are some, saith he, who attempt to take the stone out of the kidneys by incision of the ilea, but there is a great danger therein and it is an unreasonable operation.[4]

In the fourteenth century Guy de Chauliac advocated the advice given by Galen—viz., the administration of drugs to break up the stone, and he regarded stone in the kidney to be beyond the sphere of the surgeon. He says, however, that should medical treatment fail, although it is dangerous, the stone should be cut out of the bladder, but for renal calculus no operation is justifiable. Cardanus (A.D. 1501) complained that the influence of the teaching of Hippocrates had become lost by his time and strongly advised the revival of the methods advocated by the great teacher. According to Turner he thus expostulates:—

> How many operations have we lost, which were common in the days of Hippocrates? Even Galen has been so far from making addition, that he has pretermitted many useful parts of Surgery, practised by him; such as the operation for the Empiema, the cautery for tumours on the liver, the perforation of the Cranium in the Hydrops Cerebri, the Extraction of the stone from the kidney, by section, and of water *inter* cutem. All which, though many, saith he, now take upon them to perform, yet not in the manner done by the direction of the divine old man, when very many were preserved; whereas now they die under the same, scarce one surviving out of many, notwithstanding their great pretences to know more than the Ancients.

He quotes a case of Albertus[5] who reported that he saw a woman, who having been long afflicted with the nephritic illness, the place being cut into, there were taken out 18 stones of the bigness of a die. Casper Bauhine, according to Turner,[6]

> Makes mention of a young girl, born of nephritic parents, who labouring long under suppression of urine, a swelling arose about the loins, which having long waited for suppuration to no purpose, and finding only an induration of the part, the surgeon boldly cut through the same, and drew forth a couple of stones; after which her water came right as formerly, the wound being healed up. This history, saith he, I had from my master Gulielmus Capellus when I was at Paris.

In the fifteenth century the most remarkable instance of an operation upon the kidney, and the first case in which nephrotomy is supposed to have been performed for the removal of a renal calculus from a kidney that was not suppurating, is related in the Chronicles of Jean de Troyes[7] and quoted by Ambrose Paré.[8] In 1474 a free-lance of Meudon or Bagnolet was imprisoned in Chastollet because of several thefts that he had committed in various places. He was condemned to be hanged. The physicians acquainting the king that many of the citizens of Paris were troubled with stone, colic, and affection and illness of the side, more particularly one of his nobles, Monseigneur de Bochaige, and that the free-lance had been similarly troubled, having long suffered under the same disease, it was their request to His Majesty that a dissection might be made for inspecting the particular seat thereof and that an endeavour be made to extract the stone during the operation, and that the malefactor's life might be granted if he survived the same. Accordingly, at the command of the king the section was made and he ordered that it should be done very carefully. The parts having been examined the wound was sewn up and within a fortnight the prisoner was completely cured, and he was granted remission of his crimes. The man is said to have lived for several years in excellent health. The account of this interesting case is not clear and the question has been raised whether the wound was made through the abdomen, in the lumbar region, or into the urinary bladder. Ambroise Paré says that the intestines were replaced and the wound sewn up. It is very reasonable to believe that the stone was in the kidney rather than in the bladder. There is mention made of the prisoner being subject to nephritic pain, as also pain in the side of the abdomen and from the kidney by the passage of the ureter. Besides, in these days the operation for stone in the bladder was not uncommon, and would not have attracted the attention of the profession as this case has done. It appears from the account of the case that the incision was made through the peritoneal cavity, or at least the cavity was opened. Paré himself discredits this operation, and it is very difficult to know how much importance to attach to it. Certainly Paré disapproved and condemned the operation of nephrotomy. The various accounts of this case differ considerably and it would be inadvisable to place too much confidence in them.

In the sixteenth century Roussetus (1581), who had considerable experience in the Cæsarean section, records two cases of operation upon the kidney, which, however, were followed by urinary fistulæ. In one case a pyonephrosis was opened by an actual cautery by Gérard and a drainage-tube was inserted to keep the fistula open for a period of 26 years. The second case was that of a man, 20 years of age, who had suffered from nephritic colic for a long time, culminating in the formation of an abscess in the thigh, which was opened by the surgeon, and a calculus of the size of a bean abstracted. The fistula remained open until the death of the patient by accident. Roussetus takes pains to prove the practicability of lumbar nephrotomy. As far as we can understand, he wished to open the abdomen at the side, grasp the kidney in front, and cut the stone out from behind, but he never defines this transperitoneal operation as one must define it now. Turner[9] says:—

> I find Rousset has taken pains to prove it practicable, instancing, farther, where it had been done, and even proving, from the Structure of the Parts, that a good Knife's-Man may cut into the same, without dividing any large Vessels; and that both the Muscles, and the Substance of the Kidney, will bear wounding; the whole of the latter being often found wasted by Abscesses and Ulcers that leave little more than its outward Capsule, which is found like a Bag full of Sand or Stones; Yet, after all, he owns there are difficulties in the way to the operation as, the uncertainty that there is a Stone which cannot here be explored, as in the bladder, and therefore, he says it must be the last Remedy, practised only, as his Cæsarean birth, when there is no possibility of delivering the woman otherways. His words are these:—Quo ad Renem videtur vulnus, non necessario esse lethale, sive spectemus actionem et usum proprium (modo alter ren sanus et integer fit suoque satisfaciat officio) sive spectemus ipsius substantiam cum per se satis oblaesus, imo saepe ex maxima parte putridus, et per consequens vel ex parte, vel ex toto mutilis, ita ut a bono, et exercitatissimo anatomico, qui solerti, sit manu, et in similibus casibus exercitatus, possit facile, et cum honore, haec sectio administrari, sed in corpore robusto, et cum judicio solum dissecans eum locum ubi calculum persentit, cavendo, quoad fieri potest, ne vel insertionem venae emulgentis, vel ureteris exitum laedat postmodum vero consolidationem naturae committens, quod a natura praestari id possit, praeter rationem non est. Franc. Rousset. de partu Caesario apud nos. Sect. 3, p. 66.

Roussetus eventually withdrew these proposals, but for what reason is unknown.

Schenck von Grafenberg (A.D. 1584), like many of his contemporaries, approached the subject from the philosophical standpoint, theoretically agreed with Roussetus, and distinctly advised the removal of calculi from otherwise healthy kidneys. A dissertation by the French anatomist

Roilan attracted considerable attention after the beginning of the seventeenth century. He was one of the first to point out that the concretions were formed in the pelvis of the kidney and in the ureter, and he distinguished between their form. In an article which appeared in 1618 he showed that the kidneys were situated behind the peritoneum and might be reached without opening the abdomen, but that on account of their deep position he considered that it was not safe to expose them unless the situation of the organ was revealed by an inflammatory swelling. From the beginning to the end of the seventeenth century several discussions took place as to the feasability of the operation, but comparatively little actual progress was made. But certainly towards the end of the century considerable advance had been made in philosophical opinion, and in 1700 Méry strongly advocated cutting down on the kidney in order to relieve patients who were unable to be helped otherwise. Besides the above-mentioned writers, Jean Ducledat (1620), Beverwyk (1638), and Sinibaldi (1650) contributed to the discussions.

Towards the end of the seventeenth century (1670) a very distinct advance was made in the method of inquiry. Previously to the time referred to physicians knew that a kidney might become destroyed by disease or be congenitally absent without seriously interfering with the health of the individual, but experiments upon living animals to show that life could be maintained after removal of one kidney had not yet been demonstrated. The Italian Zambeccarius[10] undertook various physiological experiments upon animals for this purpose. He was the first to suggest the operation of nephrectomy and in one animal the operation was successful. S. Blancard[11] (A.D. 1690) also successfully extirpated the kidneys of dogs and mentioned that kidneys containing stones or abscesses could be operated upon after ligature of the vessels. Several surgeons who saw his operations were of the opinion that they might be performed upon the human subject, but there is no evidence that any of them ever practised nephrectomy. Blundell also performed excision of the kidney in animals. By these experiments as well as by observations in morbid anatomy, a department of knowledge still in its infancy, the surgeon of the day came to recognise that the removal or destruction of one kidney was not inconsistent with life; but, notwithstanding these indications of advancement, many surgeons opposed all operations upon the kidney. Probably the most influential writer who took up the subject was the scholarly and accurate M. Hévin,[12] who saw and examined Mr. Hobson, the English consul at Venice, whose case was, as far as we know, the first authenticated case of nephro-lithotomy. The case is one which has led to much dispute, and while the decision of most writers has been against its authenticity it appears now to have been rejected by them on insufficient grounds. The case is so important that it is worthy of description in detail. It is also due to the memory of the operator to vindicate his right to the honour of having performed the first authenticated nephro-lithotomy. Dominic de Marchetti was born in Padua in 1626, and in 1654 he published his "Anatomia." In 1662 he succeeded his father as professor of surgery, and in 1680 he became professor extraordinary of practical medicine. He died in 1688, and according to an obituary notice in Papa Dopoli's History he is spoken of as having surpassed all his contemporaries in renown for anatomy, surgery, and physics. With respect to the history of nephrectomy Mr. Henry Morris[13] says:—

> The cases of the archer of Meudon, of the British consul at Venice, and others, which had found their way into surgical literature, may be dismissed in the words of M. Hévin, who wrote in the year 1757: "It is very doubtful, if not absolutely improbable, that cutting into the kidney had ever been practised without the operation having been determined by an abscess swelling or by a fistula due to renal abscess which had broken and discharged in the lumbar region."

And in a paper read before the Clinical Society of London Mr. Morris rejects Marchetti's case in the following words[14]:—

> A precedent of undoubted authority had been much needed to give encouragement to the treatment. Surgeons do not seem to have been convinced by Marchetti's operation, doubtless partly for the reason that he does not appear to have referred to it in his own writings, and that the description which has come down to us was written by one (Charles Bernard) who was not a medical man, and to whom the facts were not narrated until ten years after the event. If this operation by Dominicus de Marchetti, of Padua, upon the English consul Mr. Hobson, towards the end of the seventeenth century, consisted, as is believed by some, in the removal of calculi which could be felt through a sinus in the loin—or, as is thought by others, after laying open an abscess of the kidney—then there is no ground for belief that nephro-lithotomy has ever been performed.

The following is the record of the case given by Dr. Charles Bernard, F.R.S.,[15] a distinguished surgeon in London, Master of the Barber Surgeons' Company in 1703, and elected surgeon of St. Bartholomew's Hospital, August 26th, 1686, upon the special command of the king, who occupied the position of serjeant-surgeon to Queen Anne:—

> This gentleman who was consul for the English at Venice, having been long afflicted with the stone in the kidney, was at length attacked with a fit of that duration and violence that it reduced him almost to desperation, and finding no relief from any means that had been used, he determined to apply himself to Dominicus de Marchetti, who, as Ch. Patin in his Lyceum Patavinum tells us, was "Primarius practiciae Extraordinariae Professor" at Padua, a famed and experienced practitioner there, the son of Peter, both well known to the learned part of their profession. To this person, Mr. Hobson, under the greatest extremity of pain imaginable, addressed himself, imploring of him that having made use of all conceivable means and the best advice that was to be had in Venice, without success, he would be pleased to cut the stone out of his kidney, being fixed in his belief that no other method remained capable of relieving him; adding that he was not insensible of the danger, but that death itself was infinitely more eligible than a life in that misery under which he had long and did then groan. Marchetti seemed very desirous to have declined it, representing not only the extreme hazard, but as he feared the impracticableness of the operation, that 'twas what he had never attempted, and that to proceed to it was in effect to destroy him. But Mr. Hobson persisting that if he refused it, he would never desist till he found out one who would do it, Marchetti was at length, by his resolution and importunity, prevailed upon to undertake it; and having prepared him as he thought convenient, he began with his knife, cutting gradually upon the region of the kidney affected, so long, till the blood disturbed and blinded his work so that he could not finish it at that attempt, wherefore dressing up the wound till the next day, he then repeated and accomplished it by cutting into the body of the kidney, and taking thence two or three small stones, he dressed it up again. From this instant he was freed from the severity of his pain, and in a reasonable time was able to walk about his chamber, having been in no danger either from flux of blood or fever. Marchetti continued to dress the wound for a considerable time, but was not able to close it up, it soon becoming fistulous from the continual flowing of the urine through the sinus; but being in all other respects restored to his former health and vigour, and the matter discharged being little, he took leave of the professor and returned to Venice under the care and management of his wife, who, one morning, as she was dressing the sore, fancied she felt something hard and rugged as she wiped it, upon which, examining a little more carefully with her bodkin, which served her instead of a probe, she found it to be a stone of the figure and magnitude of a date-stone, which, being removed, he never after complained of the least uneasiness in the part. About 10 years after this he returned to London, where the learned Dr. Tyson and myself were, by Dr. Downes who had known him formerly in Venice, invited to see him, which we did at the Castle Tavern, in Paternoster Row, when, after we had received this account from himself, he gave us the satisfaction of viewing the sore, which continued open, and permitted me without any complaint (the callosity being great) to pass my probe into the sinus so far that we concluded it reached into the kidney; the matter it then discharged was but little in quantity, but always diluted with and smelt strong of urine. The orifice would sometimes close for three or four days together, and then the matter made its way through the common passages with the urine, yet without any difficulty or pain. There is no question but that there was a coalition of the kidney and the psoas muscle. When we saw it he applied nothing to the orifice but a clean linen rag which had a strong urinous scent. He was then as able in appearance to perform all the functions of life, and to undergo any fatigue, as any man of his years, being then, I conceive, upwards of 50, and was the next day to ride about 40 or 50 miles. I have heard that he is since dead, but could not be informed of what disease.

The question of the authenticity of this case is very fully discussed by Mr. Howard Downes.[16] He says:—

> Mr. Morris gives us five reasons for rejecting the case: (1) Dominicus de Marchetti does not refer to it in his own writings. (2) Charles Bernard, the reporter, was not a medical man. (3) The reporter only heard of the case ten years after the operation. (4) Some people believe that the operation consisted of removing calculi felt through a sinus in the loin. (5) Others believe that a kidney abscess was opened and calculi found.

Mr. Downes meets these objections very fully in the paper above referred to, so that this case seems to be the first authentic instance of a surgeon cutting down upon a kidney free from suppuration and extracting from it a stone. The case, however, remained a *curiosa chirurgica*, no surgeon following the example of Marchetti, and many, indeed, considered the operation as indefensible.

Schurrigius (1744) discusses the whole question under the name "nephro-lithotomy" and takes as a text the case of a certain General Herr von Brickholz, general-in-waiting to the King of Poland and Elector of Saxony, who suffered from stone in the left kidney. In this case, however, the

surgeon refused to operate because he thought the stones were blocking the ureter too low down to be reached. When the general died examination of the body showed the left kidney to be completely destroyed and occupied by several calculi. Schurrigius[17] is certainly the first to employ the word "nephro-lithotomy," the term employed by the older writers being "nephrotomy." Joachim Camerarius[18] (A.D. 1598) relates a case in which a surgeon successfully extracted a stone that was plugging one of the ureters in a nobleman who was suffering agonies from renal colic and who demanded something to be done for his relief.

During the eighteenth century marked progress was made in our knowledge of renal disease. Human anatomy came to be more carefully studied, at least by those who aimed at being competent surgeons, and was expounded more fully to the student. The study of pathology was called into existence also. It is true that previously to this time Malpighi and Swammerdam, by the use of injections and with the aid of the microscope, had given a wonderful impulse to researches into the minute structure. Wharton had investigated the structure of the glandular organs, William Harvey (A.D. 1666–1723) had discovered the circulation of the blood, while Aselli had demonstrated the existence of lymphatic vessels; but Morgagni, who must be regarded as the founder of pathology, had still his work to do and to make his extraordinary influence felt. In Italy, a country which still retained its pre-eminence in medical science, we find during this century Pacchioni, Valsalva, Morgagni, Santorini, Mascagni, and Cotunni; in France Winslow, D'Aubenton, Lieutaud, Vicq d'Azyr, and Bichât; while in Germany the accomplished Haller and Meckel were starting a school of medicine and preparing the way for the remarkable achievements of medical science in their country during the following 150 years. In Holland scientific progress was represented by Sandifort, Bonn, Albinus, Boerhaave, and Camper; while in Great Britain the two Hunters, Cowper, Cheselden, William Lawrence, Cruikshank, Charles Bell, and the Munros worthily developed anatomical and pathological science at home. The work of these men marked a great epoch in the development of the sciences and led up to an exact knowledge of surgery.

During this period there was considerable advancement made regarding the pathology of renal and vesical calculus and the situations in which they were liable to form. Previously the idea entertained was that stones were situated either in the substance of the kidney or in the hollow behind the kidney, and that the swelling or abscess associated with calculus ruptured into the kidney and caused a swelling externally. The most important contribution to the subject is that given to us by the scholarly and accurate M. Hévin[19] (1757) in his historical and critical researches into nephrotomy. He criticises the subject very severely and even the case of Consul Hobson he rejects. The following are his opinions in respect to nephro-lithotomy:—

> To establish the possibility of an operation it is not enough to presume that it will not prove fatal to the patient, but it is necessary that science can assure the execution of it. The plans for any great operation, which is wanting in the certain rules that science demands, can only be suggested by researches and views which may lead if possible to determine exactly the technique of the operation. Great operations are always very dangerous; therefore an operation whose execution is more uncertain than its success is not a lawful one, and can only be undertaken by a surgeon who is honest and religious.

With reference to cases in which suppuration has occurred and where fluctuation can be made out in the lumbar region, or if the abscess lies outside of the kidney, he recommends that the organ itself should be cut into and the stone removed from its pelvis, by opening the kidney with the cautery, and when fluctuation is not distinct a trocar and canula should be inserted, and the wound stretched out until it is large enough to permit the stone being removed. Mr. John Douglas,[20] a surgeon of Edinburgh, records a case of old-standing renal calculus. The patient died in 1731 and at the post-mortem examination he says:—

> Having always been of opinion that there was a stone in the right kidney, I resolved first to imitate the operation called by authors nephrotomy.

This he attempted, but the difficulty was so great on account of the very muscular condition of the subject that he failed to reach the stones and had to open the body in front.

NOMENCLATURE AND CLASSIFICATION.

BY CHARLES POWELL WHITE, M.D. CANTAB., F.R.C.S. ENG.,
DEMONSTRATOR IN PATHOLOGY, THE YORKSHIRE COLLEGE, LEEDS.

A UNIFORM and logical system of nomenclature and classification is a great help in the study of any science. In medicine it is to be feared that such a system is impossible, but, at any rate, our present systems are capable of great improvement and it is my object to endeavour to show in what ways we can effect this improvement. Our conception of what a disease is will vary according to the standpoint from which we regard it. On the one hand, we can say that a disease is characterised by a definite causal agent, and on the other, that it is characterised by definite lesions. We, therefore, have two systems of nomenclature and classification—one based on cause and the other on effect. Both these systems are useful, and, indeed, necessary, but neither can take the place of the other. There are some names (e.g., syphilis) which have no inherent pathological meaning; these have mostly come to be regarded as having an etiological significance.

NOMENCLATURE.

The chief factors concerned in producing the unsatisfactory state of medical nomenclature are (*a*) the bias of antiquity, (*b*) the bias of authority, and (*c*) the progress of knowledge which has caused us to look upon diseases from a different aspect to that from which our forefathers regarded them. A name should comply with certain conditions: it should be classical, preferably Greek, in form; it should express by its derivation the condition to which it is applied; its form should correspond with that of other names expressing corresponding conditions; and it should not be too cumbersome. Although we cannot hope to create an ideal system of nomenclature we can improve the present system to a great extent (1) by removing illogical and redundant terms; (2) by always using corresponding terms to express corresponding senses; (3) by making new names to express new meanings instead of altering the meanings of established words; and (4) in the case of alternative words by choosing that which best expresses the condition.

1. *By removing illogical and redundant terms.*—The most important of the illogical terms at present in use are the prefix "pseudo-" and the qualifying adjective "false." It would be a great improvement in medical nomenclature if these two terms were entirely removed. Why, for instance, should we call a fibroma of a nerve a "false neuroma"? We might with equal reason call a fibroma of the kidney a "false adenoma." These terms have arisen from the advance of pathological knowledge and the consequent alteration in the meaning of terms. For example, the term "tuberculosis" used to mean a disease characterised by the presence of certain structures called "tubercles"; now, however, it means a disease due to the bacillus tuberculosis and, in consequence, some diseases which, having the necessary tubercles as characteristics, would rightly be included in the term in its old sense, now are indicated by the term "pseudo-tuberculosis." Among redundant terms which might be discarded with advantage may be mentioned "atheroma," "epithelioma," &c. The term "cirrhosis" should be used in a clinical sense only; "fibrosis" is a much better term to express the pathological condition of increase of fibrous tissue.

2. *By always using corresponding terms in corresponding senses.*—This is especially necessary in prefixes, suffixes, &c. Terminations:— *-trophy.*—This termination, which really implies nourishment, is always used to imply growth, and it should be restricted to this sense. *-plasia.*—This implies development and it should have this meaning whatever prefix is attached to it. The usual definition of hyperplasia that is given is "hypertrophy by increase in the number of cells," as opposed to simple hypertrophy, which is "hypertrophy by enlargement of individual cells." This, however, implies a meaning of the termination which is not found in the other words of which it forms part; moreover, it is not sufficiently definite because it includes too much. For instance, the term "hyperplasia of the liver" does not indicate whether the change is due to an increase in the number of the lobules of the liver or to an

increase in the number of cells in each lobule. Again, hypertrophy of the kidney may take place in three possible ways. 1. By an increase in the number of tubules and glomeruli. 2. By an increase in the size of individual tubules, the number remaining the same: (*a*) by an increase in the number of cells in the tubule, and (*b*) by enlargement of individual cells. With the ordinary meaning of the terms 1 and 2*a* would both be included in the term "hyperplasia," although they are totally distinct processes. I should call 1 "hyperplasia," 2*a* "numerical hypertrophy," and 2*b* "simple hypertrophy," and I should express the difference between hyperplasia and hypertrophy as exactly that between development and growth. That this is a true distinction is shown by the fact that hyperplasia, as I have defined it, only occurs during the period of development (at least, if compensatory in origin), and that simple and numerical hypertrophy are usually associated together. For instance, if one kidney fails to develop the other undergoes hyperplasia; but if one kidney, having developed, undergoes atrophy or is removed the other undergoes hypertrophy. *-ergia.*—We have the termination "-trophy" and "-plasia" to express growth and development, and I have proposed to introduce the termination "-ergia" to express functional activity; thus "hyperergia" would mean "increased functional activity." *-aemia.*—This termination has two significances, one referring to the condition of the blood and the other to the distribution of the blood in the vessels. This is unfortunate but it would seem to be unavoidable. The other terminations do not need discussion as there is no ambiguity in their use. Prefixes:—Prefixes should always be used systematically and in different words should express the same meaning. The prefix *a-* or *an-*, which really implies absence, is sometimes unfortunately used in the sense of diminution, as in the word a-trophy. In the word an-æmia it implies sometimes absence and sometimes diminution. Strictly speaking, "atrophy" should mean that the part though developed had not grown; it is, however, always used in the sense that the part which had grown afterwards has diminished in size. The prefix *ana-* is sometimes used in this sense, as in the term "anaplasia," which means "backward development." The prefix *hypo-* implies deficiency and should not be used as implying absence. The other prefixes need not be discussed. Suffixes:—*-oma.*—The suffix "-oma" should be limited to the designation of the true tumours and it should not be applied to other conditions. The term "atheroma," besides being redundant, is used in more than one sense and there would seem to be little advantage in retaining it. *-osis.*—This suffix expresses (*a*) an overgrowth or multiplication of the structure designated by the root to which it is affixed. Thus fibrosis means an overgrowth of fibrous tissue and fibromatosis implies multiple fibromata. (*b*) Sometimes this suffix implies that the cause of the disease is expressed in the root to which it is attached; thus anthracosis is a disease due to coal-dust, aspergillosis is a disease due to the growth of an aspergillus, &c. The suffix, therefore, has sometimes an anatomical, sometimes an etiological, significance. *-itis.*—This suffix has an anatomical significance and implies inflammation, and the root to which it is attached should express the organ or tissue which is inflamed. Some authors recently have expressed a wish that the term "inflammation" and the corresponding suffix should be removed from medical nomenclature. This, however, is impossible, as we should in that case have no terms to describe the inflammatory conditions as met with in the post-mortem room. A purely etiological nomenclature can never be suitable for the purpose of describing anatomical conditions, since a specific causal agent does not always give rise to the same morbid lesion, and no single lesion is always due to one and the same causal agent.[1]

3. *By inventing new terms to express new meanings instead of altering the meanings of established words which already have a definite significance.*—For instance, the word "diphtheritic" has long been used to describe a particular form of inflammation and there is no other word to express this meaning. When, however, the disease "diphtheria" was isolated and found to be due to a specific bacillus there was a natural tendency to limit the application of the term "diphtheritic" to conditions met with in diphtheria and so to alter its significance altogether. It is much more satisfactory to leave "diphtheritic" in its old sense and to use the term "diphtherial" as the adjective of "diphtheria." This is done by many writers and editors at the present day and it would be a great advantage if it were the universal custom.

4. *In choosing between two alternative names that one is to be chosen which best expresses the condition*—Thus, "leucocythæmia" is to be preferred to "leukæmia," and "fibrosis" to "cirrhosis," &c.

Nomenclature of tumours.—I have given elsewhere[2] my views as to the nomenclature and classification of tumours, so that I need say very little about them here. Simple or tissue tumours are to be named by affixing the suffix "-oma" to the root expressing the name of the tissue which constitutes the essential part of the tumour. Exceptions occur in the case of epithelial and endothelial tumours since the terms "epithelioma" and "endothelioma" have been applied to malignant growths. The place of these terms is taken by the terms "papilloma," "adenoma," "angeioma." I should call any simple epithelial tumour in which the epithelium forms tubes and spaces lying in a connective tissue stroma an "adenoma," whether the growth starts from a gland or from a surface epithelium. Carcinomata are to be named according to the kind of epithelial cells of which they are constituted; such words as "adeno-carcinoma" are not necessary and only lead to confusion. Cancer.—Most writers at the present day use the term "cancer" as synonymous with "carcinoma." In this sense the term is redundant and therefore unnecessary. It would be much more satisfactory to revert to the older meaning of the word as signifying any malignant growth, since we often have occasion to speak of malignant growths without specifying whether we are speaking of carcinoma or sarcoma.

Another direction in which reform is desirable is in the use of the word "coagulate." This is applied indifferently to the change which occurs in albuminous bodies by the action of heat, alcohol, &c., and to the changes occurring in the clotting of blood or muscle. There would seem to be no reason for this double use of the word.

CLASSIFICATION.

It may be said at once that it is absolutely impossible to find a system of classification which shall be useful for all purposes. A disease is not a definite entity, but is an action. It has been defined as "an abnormal interaction between the structure of the living body and its environment."[3] Our conception of disease is therefore inseparable from life. For example, we can speak of lead intoxication as a disease, but it is not the lead that is the disease, nor is it the effect that lead produces on the body, but it is the action of the lead on the living body. Since, then, diseases are not entities we cannot classify them in the same way as we classify material substances; we can only classify them according to the cause of the disease or according to the effects that are produced on the body. Classification by cause is useful for the systematic consideration of diseases, as, for example, in a text-book of medicine or surgery. When, however, we have to do with clinical symptoms or morbid conditions of the different organs the most useful system of classification is by the effects produced on the body by the causal agent. Whenever we make a diagnosis we make a mental classification by effect. We first observe the effects of the disease and then by successive stages we arrive at a conclusion as to the cause. We thus in diagnosis and in the post-mortem room argue from effect to cause and not *vice versâ;* in the systematic study of diseases, on the other hand, we often argue from cause to effect.

The confusion arising from the use of an illogical and unscientific system of classification is seen in the result of classifying tumours on an embryological basis. In this system carcinoma is said to be epi- or hypo-blastic in origin; those, therefore, who adopt this system must, if they are consistent, deny the existence of carcinoma arising from the renal, testicular, ovarian, or uterine epithelium. Moreover, since the neuroglia is almost certainly epiblastic in origin, the gliomata should be included among the epiblastic rather than among the mesoblastic tumours. At a recent meeting of the Pathological Society of London one of the members is reported to have doubted the existence of carcinoma arising from the hepatic cells because it has been suggested that these cells are of mesoblastic origin.[4] There is no reason whatever why we should classify tumours according to the layers of a three-layered embryo; it is much more scientific

[1] The Relation between Cause and Effect in Disease, Brit. Med. Jour., Dec. 15th, 1900.

[2] Journal of Pathology and Bacteriology, vol. vi., p. 220.

[3] Harry Campbell: The Causation of Disease, London, 1889.

[4] THE LANCET, Jan. 19th, 1901, p. 180.

to classify them on a histological basis, since we can observe their structure and can only infer which embryonic layer they belong to.

Any classification should satisfy certain conditions. 1. It should be based on observable facts and not on inferences. 2. In dividing a class into sub-classes the basis of division must be the same for each sub-class formed; thus it is wrong to divide cirrhosis of the liver into multilobular, monolobular, and syphilitic, as is done in many text-books. 3. The sub-classes of any class should be mutually exclusive—i.e., there should be no overlapping. 4. The sub-classes when added together should include the whole of the class and no more.

Classification by cause.—The factors concerned in the causation of disease can be divided into (*a*) extrinsic and (*b*) intrinsic. A cause which is extrinsic as regards a particular organ may be intrinsic with regard to the whole body. Causal factors can also be divided into (*a*) essential and (*b*) adjuvant, the essential cause being that without which the disease could not occur and the adjuvant causes being those which assist in the production of the disease without in themselves being individually necessary. We can therefore classify diseases as follows. 1. Diseases in which the essential factor is extrinsic—(*a*) parasitic diseases; (*b*) intoxications; (*c*) diseases due to physical or chemical irritants; (*d*) diseases due to alteration in amount or pressure of the surrounding medium; and (*e*) diseases due to altered nerve-supply, &c. The processes concerned in these diseases are inflammation, consecutive atrophy, consecutive hypertrophy, degenerations, &c. 2. Diseases in which the essential factor is intrinsic. For example, those diseases which are characterised by the processes primary atrophy, progressive hypertrophy, tumour formation, maldevelopment, &c. The actual nature of the intrinsic factors in the causation of disease is unknown to us; we cannot, therefore, subdivide the second class in the same way as we can the first. It is obvious that it is very difficult to allot a place to every disease in this system of classification.

Classification for general pathology.—General pathology is the study of pathological processes, their causes and effects, without reference to any particular locality or disease. In any scheme of classification for general pathology we must provide for certain processes or conditions which may be called "physical"—namely, those processes or conditions which depend purely on physical causes. Such are the distension of blood-vessels in obstruction of the circulation and the emptying of the vessels beyond the obstruction, the distension of ducts from obstruction, wounds, deformities, &c. We might classify the pathological processes as to cause in accordance with the scheme given above, dividing them into (*a*) consecutive processes, and (*b*) primary processes. We should subdivide (*a*) according as the processes are the result of irritation, alteration of blood-supply, nerve stimuli, functional activity, &c. This method has the disadvantage that the processes "atrophy," "hypertrophy," &c., would appear under (*b*) and also under most of the subdivisions of (*a*). We might, on the other hand, classify them according to the nature of a process thus: (*a*) alterations of development; (*b*) alterations of growth; (*c*) alterations of functional activity; (*d*) degenerations, &c.; and (*e*) physical. The best method, however, is as to the results of the processes.

If we consider the strictly pathological processes we find that we can divide them into three groups. 1. Those which are characterised by a destruction or diminution of tissue or functional activity (destructive processes). Such are atrophy, hypo-ergia, &c. 2. Those which are characterised by a replacement of tissue or functional activity lost, or by an increase to meet extra demands (reparative processes). Such are repair. regeneration, and the compensatory processes. Inflammation would also come under this heading as a preparation for repair. 3. Those which are characterised by an actual increase of tissue or functional activity beyond the needs of the organism (constructive processes). Such are tumour formation, &c. I should subdivide the first group into primary and consecutive processes, and the third into those which are collateral, such as hypertrophy from increased blood-supply without any demand for extra work, and those which are progressive, such as tumour formation, &c.

Our knowledge of the infiltrations is too incomplete to allow us to assign them their proper place in this classification. In accordance with custom they may be provisionally classed with the degenerations.

SCHEME OF CLASSIFICATION FOR GENERAL PATHOLOGY.

A. Etiology, including parasitology.
B. Developmental errors: monsters; malformations (aplasia, hypoplasia, hyperplasia, and kakoplasia—i.e., irregular development); and malpositions.
C. Physical processes: deformities; displacements; solution of continuity; distension of tubes and spaces; and blocking of tubes and spaces.
D. Cessation of physiological processes: necrosis.
E. Destructive processes: consecutive (atrophy, anergia, &c.; degenerations, &c.); and primary (atrophy, anergia, &c.).
F. Reparative processes: inflammation, repair, regeneration; compensatory hypertrophy; compensatory hyperergia; and compensatory metaplasia.
G. Constructive processes: collateral—e.g., hypertrophy from increased blood-supply; and progressive (progressive hypertrophy, progressive hyperergia, progressive metaplasia, and tumour formation).

Classification for macroscopic morbid anatomy (museum or post-mortem room).—In the arrangement of a museum one section should be devoted to specimens illustrating general pathological processes. This section is best arranged on an etiological basis and it should contain specimens illustrating the various processes and also typical specimens illustrating diseases which are not limited to any particular organ, such as tuberculosis, metastatic carcinoma, &c. It should also contain specimens of the various parasites, animal and vegetable. The rest of the museum should be divided into sections corresponding with the different systems, each of these sections being subdivided according to the organs in the system. In the case of the bones classification should proceed according to the scheme to be given before subdividing according to individual bones, and this should be the case with regard to the joints, muscles, &c. The primary classification should be based on the macroscopic appearances and not on etiology. Cause should be used as a basis of subdivision. In this scheme the inflammatory conditions present the greatest difficulty. I think that the best division is into non-suppurative, suppurative, and ulcerative; they could then be subdivided into diffuse and nodular conditions. Fibrosis (sclerosis in bone, &c.) should be accorded a separate class because it is not necessarily a post-inflammatory condition. Inflammatory conditions and tumours should, if possible, be subdivided according to the portion of the organ affected; thus, tumours of bone should be divided into central and peripheral growths. Cathcart[5] advocates the classification of a museum on an etiological basis, but his system is open to many objections. In the post-mortem room, as at the bedside, we argue from effect to cause and not *vice versâ*. If, then, the museum is to be of assistance in clinical work the primary basis of classification should be the effects produced on the organs by disease, cause being used as a basis of sub-classification. Another objection to Cathcart's system is that similar conditions of an organ, instead of being placed together, would be found under several headings; there is also an unjustifiable separation of syphilis from tuberculosis, the one being called a blood poison and the other a local irritation.

SCHEME OF CLASSIFICATION OF THE MORBID CONDITIONS OF THE DIFFERENT ORGANS.

A. Alteration in form or position: malformations; deformities; malpositions; and displacements.
B. Alteration in structure: metaplasia—e.g., ossification of tendons.
C. Solution of continuity: wounds, fractures, &c.
D. Repair—e.g., cicatrices, healing of fractures, &c.
E. Disturbances of circulation: hyperæmia, embolism, &c.
F. Retrogressive changes: atrophy; and fatty, calcareous changes, &c.
G. Inflammatory conditions: non-suppurative (diffuse and nodular—e.g., tuberculosis, &c.); suppurative (diffuse—e.g., cellulitis, and abscess; and ulcerative).
H. Fibrosis (sclerosis).
I. Necrosis (gangrene).
J. Hypertrophy: compensatory and progressive.
K. Tumours.
L. Cysts.
M. Animal parasites *in situ*.

Classification for clinical purposes.—It is not possible to give a complete scheme of classification for clinical purposes, since it will necessarily vary according to the organ which is affected. The natural system is one based on the symptoms to which the diseases give rise. Thus, we speak of diseases of the liver associated with ascites or jaundice and we divide affections of the serous membranes into those with and those without effusion, &c.

Classification for histological purposes.—In classification for histological purposes we use as our basis the histological characters of the lesions found in the disease; thus, we divide inflammations of the kidney into glomerular, tubal, and interstitial nephritis. In describing the microscopic

[5] Classification in Pathology, Edinburgh Medical Journal, 1896, vol. xlii., pp. 37, 141.

appearances of any lesion we should not use words implying an etiological classification such as "syphilitic cirrhosis," "scarlatinal nephritis," &c. As examples of these various systems of classification let us consider cirrhosis of the liver. 1. Classification according to the cause: (*a*) alcoholic; (*b*) syphilitic; (*c*) biliary; and (*d*) post-febrile, &c. 2. Classification according to the symptoms: (*a*) cirrhosis with ascites; and (*b*) cirrhosis with jaundice. 3. Classification according to the macroscopic appearances: (*a*) small cirrhotic liver; and (*b*) large cirrhotic liver; or (*a*) hobnail liver, and (*b*) smooth cirrhotic liver. 4. Classification according to the histological appearances: (*a*) multilobular; (*b*) monolobular; and (*c*) pericellular. 5. Classification according to the nature of the fibrotic process: (*a*) inflammatory; (*b*) replacement; and (*c*) progressive. It will be noticed that no two of these classifications coincide and that a system which is suitable for one purpose is not suitable for another.

In the foregoing remarks I have endeavoured to indicate some of the rules that should guide us in the construction of names and schemes of classification. It has been impossible to give more than a few examples, but those given are, I think, sufficient to show that nomenclature and classification should proceed according to definite rules and not in the hap-hazard manner which is too common at the present day.

Leeds.

THE ROYAL COMMISSION ON SOUTH AFRICAN HOSPITALS.

(Continued from p. 657.)

III.

IN our issue of March 2nd we gave an abstract of the report of the Commission as far as it dealt with matters up to the occupying, and advance from, Bloemfontein. We now continue the abstract of the report as it deals with the advance to Pretoria and the incidents which occurred on the way.

The advance to Kroonstad was, say the Commissioners, similar in most ways to the advance to Bloemfontein, though the condition of affairs was somewhat better. The sick and wounded accumulating during the advance were sent back to Bloemfontein, except some who were detained for a time at Glen and at Karee. As to the passage by railway from the rail-head to Bloemfontein the Commissioners say:—

As a rule the men were properly supplied with necessaries, but there were cases of prolonged detention when there was a deficiency of supplies. And the open trucks which had generally to be used for the less serious cases must have caused hardship to their occupants. We ought, however, in considering this subject, to observe once for all, with regard alike to this particular advance, to the advance upon Bloemfontein, and also to the subsequent advance of the army to Johannesburg and Pretoria, that, though men may have fallen out from the ranks during the march, there is no real foundation for the suggestion that to any appreciable extent sick or wounded men were left lying on the veldt unattended.

There is one incident connected with this advance referred to in Mr. Burdett-Coutts's evidence which we should particularly notice. It concerns the repulse of the Inniskillings and the Scots Greys. It is said that the wounded were left unattended from 9 A.M. to 4.30 P.M. and that they were then taken to a tin hut by Major Eames, of the New South Wales Bearer Company, and left in charge of a civil surgeon there; that two days afterwards an order was sent to the civil surgeon that the hut must be evacuated; that he protested, on the ground of the condition of the patients, against the order, but that he was obliged to carry it out notwithstanding his protest, and that the sick and wounded were sent away by ox-wagons, excepting only three officers who were detained in the tin hut under the care of a doctor. Mr. Burdett-Coutts adds that it appeared to him that the detention of these three officers alone was an unfair distinction. The facts of the case appear to be as hereafter stated, from which it will appear that any suggestion of unfairness in the treatment of the officers and privates is wholly unfounded. The troops were mounted and had been fighting a skirmishing action in front and it was quite impossible for ambulances to keep up with them. When the loss to the Inniskillings and Scots Greys occurred the wounded could not be collected until some ambulances came up. The first to come up were the ambulances of the New South Wales Ambulance Corps which was well in front and provided with good horses instead of mules. These ambulances at once gathered the wounded men without any undue delay and took them first to a Kaffir kraal where they were tended for a night, three surgeons being present, one of them a gentleman temporarily serving as a private. The next day the men were removed to a tin house at Ventersberg Siding and there they were operated on and carefully and properly attended to by the three surgeons, assisted by Mr. Cheatle, one of the civilian consulting surgeons. Then the surgeon who had been previously serving as a private volunteer was left in charge after his skill had been tested by the other surgeons. Some days after this the wounded in the hut had to be removed, so far as they could be without injury to themselves, on account of the military situation and the fact that the enemy were threatening the position. Before the removal three surgeons had consulted together and selected those patients who, in their opinion, could be removed with safety. No protest of any kind was made in respect of the removal by any surgeon. They all agreed that the patients who were sent could properly be removed. Three patients, and three patients only, were kept because their condition was such that they could not be transported with safety to themselves. Of those, two were officers and one was a private. Their injuries were very severe. They were kept wholly irrespective of rank and entirely upon considerations of their medical condition. That no question of rank entered into the determination of the matter is obvious, not only from the nature of the wounds of the men who remained, but from the fact that amongst the patients who were sent away were included three officers.

Glen and Karee Siding Hospitals.

We may here deal shortly with the condition of the hospital at Glen. Between 200 and 300 patients were kept there during the advance under the charge, as above mentioned, of the 14th Brigade Field Hospital. Complaints have been made, and justly, with regard to the site of the hospital. It was, no doubt, a bad site and unsuitable for a hospital. Lying in a hollow, it was liable to become extremely damp during wet weather, and, accordingly, we find that the men in the tents did complain greatly of the state of the ground on which they were lying, and said that they had become worse instead of better since they had been placed there. The Rev. Robert McClelland, acting as a Presbyterian chaplain to the forces, who gave evidence as to the condition of the hospital, visited it on the 28th April, and he points out how, on removing the waterproofs under the blankets of the men, he discovered a fungus growth existing there. This is sufficient in itself to show the nature of the ground. We inquired from the officer who selected the site (Major Faunce) how it came to be chosen. He said that it was the only possible site that could be selected, because there were military reasons against encamping on higher ground, and then goes on to say: "We should have been behind the outposts and there were other military reasons; in fact, there was no other ground at Glen where we could have encamped, and it was the only clean piece of ground."

It is difficult for us to judge whether another and better site might not have been selected. The hospital was, in fact, evacuated shortly after Mr. McClelland visited it. Apart from the nature of the site there are not many complaints with regard to this hospital except those inseparable, as previously pointed out, from the fact of a field hospital being used as a fixed one. Probably it is to this evacuation that Mr. Burdett-Coutts alludes when he speaks of a convoy being subjected to nameless torture owing to the patients being huddled together in rough springless ox-wagons and jolted over spruit and drift for 40 miles. In his evidence he informed the Commission that in his statement he referred to a convoy which came from Glen some time about the 28th April, and as the 14th Brigade Field Hospital reached Kroonstad on the 14th May Mr. Burdett-Coutts's date would coincide closely with the period of its evacuation. It should be noted, however, that Glen is only 14 miles from Bloemfontein and not 40 miles.

With regard to the temporary hospital formed at Karee it appears to have been overcrowded and to have had the usual drawbacks attributable to a hospital formed under its conditions.

KROONSTAD.

With regard to Kroonstad itself the town was small and the buildings which had to be taken for hospitals—the only existing hospital being full of Boers and British prisoners—were not well suited for the purpose. There were undoubtedly great pressure and corresponding discomfort for the patients, but after the line to Bloemfontein was open the state of matters improved. The army of occupation arrived on May 12th and soon after the state of matters is well shown in the following extract from the report:—

On the 16th May Major Ford of the 18th Brigade Field Hospital took charge of the buildings. Several witnesses bear testimony to the great credit due to this officer for what he did under very trying and adverse conditions, and in our opinion the work he did was, under the circumstances, remarkably good. Those difficulties, as may be easily seen, were very great. For the first few days the staff of the 19th Brigade Field Hospital had practically alone to look after all the sick and wounded in the town though the field hospital of the 3rd Cavalry Brigade appears to have been there for two days. (*Vide* Minutes of Evidence—Captain McMeekan.)

Such a staff was wholly insufficient in numbers and equipment to look after the patients requiring attention. At the time that Major Ford took over the buildings there were in the Kroonstad Hotel 16 officers and 127 men (not 200 as one witness has stated). These men were placed chiefly in the dining-room of the hotel, and all, with the exception of about a dozen, had mattresses. With regard to these latter men, directly Major Ford took command of the building he at once commandeered mattresses for them, and on the next day all the patients in the hotel were provided for. Dr. Manning, a local doctor, was placed in charge of the Grand Hotel to which about 150 patients were removed from the field hospitals on Lord Roberts's advance. Dr. Manning as a civil surgeon was, of necessity, not much experienced in military hospitals, but did well under the circumstances, having to assist him only 15 untrained orderlies. This hotel had not been prepared for the reception of the patients when they first came in, and the rooms in which they were placed were very inconvenient. Great discomfort was, of necessity, suffered by the men, and there was great difficulty in attending to them at all. The men had to lie on the tables and floors of the buildings, and could not be, and were not, properly looked after or nursed for the first few days. But all the patients within three days after the occupation of the hotel had mattresses to lie upon, or their equivalents, and the worst cases had change of clothing provided for them within two days after the hotel was first taken. On the 22nd May Major Ford cleared some of the patients from this hotel to the Rest Camp which had been prepared, and within the next three days the hotel was cleared of all the patients except a few officers who were left in the small rooms on the upper floor, where, having their own servants, they could be properly attended to. There these officers remained until the hotel was closed altogether as a

hospital. Of the privates sent out from this hotel by Major Ford 50 were sent to the Rest Camp, 60 were sent down by convoy to Bloemfontein, and the rest were accommodated in the Dutch Church which was then taken over and turned into a hospital.

On the 17th May the Town Hall was taken and patients placed in it. It was small and inconvenient and very unsuitable for a hospital and was only used because of the great pressure for room existing at the time. 70 patients were temporarily placed there, but the building was only used as a hospital for four days and was then closed. During these few days the men there, or most of them, had mattresses to lie upon, but they must have suffered considerable discomfort. When the hall was given up the patients in it were moved to the Dutch Church. During the temporary occupation of this town hall no separate doctor was in attendance and the patients had to be looked after by the doctors attached to other buildings when they could be spared.

The Dutch Church was first taken and used as a hospital about the 20th May. It was the best building in the town available for the purpose, being large and airy. There was a difficulty originally in ventilating it properly owing to most of the windows being permanently closed, but this difficulty was overcome by the tops of the windows being broken. The church had not a stone floor, as was stated inadvertently by Mr. Burdett-Coutts; it had a wooden floor and the building stood in a large and airy compound which was soon utilised for the sick and wounded by tents being placed in it. For this purpose the compound was very suitable. It had not been used as a burial ground, as has been suggested, but was a perfectly sanitary and good site. Mattresses were obtained for all the patients as they were moved into this church.

In these ways accommodation of a rough kind was provided for all the sick and wounded in Kroonstad. For the first few days after its occupation there were very few doctors in the town, though their number has been somewhat understated by some witnesses owing to their not being aware of, or forgetting, the existence of the doctors in the Boer hospital. At first there were only five doctors in the town. Then shortly afterwards, and before the 25th May, two more doctors arrived. But these were too few in number to properly look after the number of sick and wounded in the town. Orderlies, and especially trained orderlies, were also insufficient in number, and could not cope properly with their duties. There was also an insufficiency of bedpans, commodes, urinals, and so forth. These deficiencies of necessity led to results similar to those which we have pointed out with regard to Bloemfontein in its early days and need not be repeated here. On the other hand, there appear to have been at Kroonstad sufficient medicines, medical appliances, and comforts, such as brandy, wine, jellies, &c.

Owing to the above condition of matters, and also to the fact that Kroonstad itself was for some time threatened by the enemy, it became advisable that all patients who could stand the journey should be removed by convoys to the rail-head for the purpose of being sent down by rail to Bloemfontein. For some time the rail-head to which they were sent was the station at Zand river, the railway between that and Bloemfontein being ready at a comparatively early date. Accordingly, patients were selected to be sent down. The best selection we believe was made that circumstances permitted; at any rate, we are satisfied that the medical officers did their best to judge fairly as to the condition of those selected for the journey, though, of course, in individual cases mistakes may have been made. The men were sent down with such provisions for their comfort during the journey as could in the emergency be provided. But at times (especially when the enemy threatened the town and the lines of communication) the convoys had to be sent hurriedly, and the provisions for their journey down could not be made in a satisfactory way. To many men in some of these convoys there must, of necessity, have been considerable suffering caused during the journey, but as a whole they bore the journey well. Surgeon-General Wilson in his evidence says that he saw them on their arrival at Bloemfontein up to the date he left that town and that they arrived in a satisfactory condition. But it was not always possible to send any convoys away, owing to the interruption of the lines of communication by the enemy. For example, on the 20th May, a convoy had been arranged to start with 200 men in it for Bloemfontein, and the men were put into the wagons prepared. It was then found impossible for the convoy to be sent with safety and the men had accordingly to be shifted and accommodated again in the town.

On the 22nd May the advance of Lord Roberts from Kroonstad commenced, and of course the field hospitals, having to accompany the troops, were cleared of patients who had to be accommodated elsewhere. All the field hospitals did not accompany the advance, inasmuch as one-half of the 18th Brigade Field Hospital had to remain behind until the general hospitals could be got up to Kroonstad. We have evidence as to the state of the buildings occupied as hospitals at the date of the advance. According to Major Ford it appears that in the Grand Hotel there were 174 patients with one medical officer and 20 orderlies (mostly untrained) to attend upon them. In the Kroonstad Hotel there were about 25 officers and 170 men to be attended to. In the Dutch Church and Compound there were 200 patients, 90 being in the church itself; to attend to these there were two medical officers and four trained orderlies, the rest being merely regimental. In the Russo-Dutch Hospital there were 20 officers and from 80 to 100 soldiers with two doctors to attend. This does not show a satisfactory state of things.

By the 25th May the railway line up to Kroonstad was made fit for traffic and on or about this day the first train from Bloemfontein arrived. The opening of railway communication greatly relieved the pressure of things in Kroonstad. Surgeon-General Wilson came by the first train and brought up the *personnel* of the Scottish Red Cross private hospital, and the staff and equipment of half of No. 3 General Hospital, the remaining half arriving shortly after. He also brought some nurses, orderlies, and hospital equipment. On the 26th May there were sent from Bloemfontein to Kroonstad 500 mattress cases; on the 1st June 200 beds were sent up, and 300 more on the 6th.

No. 3 General Hospital on its arrival helped to supply beds for such patients in the buildings used as hospitals as had up to that time only had mattresses to lie upon. Part of the staff of this general hospital took over the Dutch Church from the 18th Brigade Field Hospital, which then advanced and joined the army at the front. No. 3 General Hospital opened and took in about 140 patients on the 28th and 29th May. In this hospital, for the first few days after its occupation slight cases had to remain in bell-tents lying on mattresses. The severe cases were accommodated in marquees.

Professor Henry Edward Clark, chief surgeon in charge of the Scottish Hospital, in his evidence shows how urgently aid was needed at Kroonstad on the 25th May when he arrived. He found all the buildings which had been taken as hospitals overcrowded; for instance, he found men in the Grand Hotel lying on and under the billiard table and on the settees and floors. All had mattresses, but three-fourths of them had no bedsteads to lie on. Owing to the lack of orderlies and utensils he found that some men had remained unwashed for some few days and that their clothing remained unchanged, even, in a few cases, when fouled by evacuations. He further says that sometimes men could not get proper comforts and that there was a temporary deficiency of certain medicines, and he adds that this condition of affairs lasted till about the 8th June. Dr. Cowan, of the same hospital, however, points out that the very severe cases were attended to, and other witnesses show by their evidence that all essential drugs were forthcoming.

Immediately the railway was opened patients were sent down by it to Bloemfontein both from the buildings and from the field hospitals. For this purpose the hospital train, which had been telegraphed for by Surgeon-General Wilson immediately on his arrival in the town, was used for the conveyance of severe and bad cases, and the men in these hospital trains could be, and were, sent to Bloemfontein with comfort. Cases not so severe had to be, and were, sent by ordinary trains. A selection was made as to the men to be sent down and as to the kind of train by which they should travel. As a rule, we think that proper food and comforts were provided for the men on their journey, though there have been some complaints in certain cases where food and proper comforts are said to have been insufficient. No doubt cases of the kind did occur, though not, we think, frequently. In the case of the ordinary trains, owing to lack of better carriages, some patients had to be sent down in open trucks. These were slight and non-fever cases. Some of these trains had no doctor or trained orderlies accompanying them, for the reason that at Kroonstad at the time there were none available to send. But in these cases regimental orderlies were sent, and some of these being medical students who had volunteered were very suitable for the purpose. The food and comforts necessary for the journey were committed to the care of the senior non-commissioned officer accompanying the train. However, at times there must undoubtedly have been considerable suffering in these trains.

In one respect Kroonstad differs from Bloemfontein, inasmuch as from its very first occupation commandeering was resorted to, and in this way most necessaries were obtained for the hospitals. We think, however, that with regard to a few things commandeering was not pushed to the full extent that it might have been.

On the day after Kroonstad was first occupied the landrost was told to commandeer for 200 mattresses and 400 blankets. He did so and obtained the quantities required and even more, and these were put into the Dutch Church. The landrost also obtained stretchers and had more made. He further commandeered for and obtained many bedsteads and much linen. Still there was a delay in obtaining a few articles; for example, more bedsteads might have been obtained at an earlier period. Professor Clark says that some beds were required by his hospital and were bought by his junior officer in the town as late as the 10th June. We can only attribute this delay in the early days to the confusion caused by the military occupation of the town and the fact that the medical officers were wholly occupied with looking after the sick and wounded. But this does not explain the later delay, unless, indeed, the landrost's explanation be correct—namely, that more bedsteads were not commandeered or ordered because, even had they been obtained, there was no room for them at the time in the buildings which were then occupied. At the same time, as Professor Clark points out, the patients did not appear to suffer to any serious extent from the lack of bedsteads, and he endorses the statement that several of the rooms in the building which had been taken and which were being used could not have accommodated so many patients if more bedsteads had been used.

With regard to fresh milk there was the usual deficiency, but though a few individuals in the town may have been able to obtain some we think on the evidence as a whole that no substantial increase of milk could have been obtained by the medical authorities.

By the 3rd June the trains had removed so many patients that the overcrowding in the town was greatly reduced, and by the 8th June its troubles were to a great extent over. It is clear from Colonel Richardson's evidence that there were at Kroonstad, from and after the 9th June, ample supplies of all kinds for the hospitals at Kroonstad. All witnesses are practically agreed that by the third week in June matters were put on a satisfactory footing and the grounds of complaint to which we have called attention disappeared. As things improved the buildings which had been taken were gradually cleared of their patients. The Kroonstad Hotel was cleared on the 21st June, the Russo-Dutch Hospital on the 27th June, the Dutch Church on the 31st July, and the Grand Hotel (which had only been used for officers from the date of the arrival of No. 3 General Hospital) on the 31st August, shortly before the Commissioners arrived there.

We have investigated the subject, and on the whole, bearing in mind the difficulties in the way, we think there was no undue delay on the part of the medical authorities in getting up the general hospitals. As we have pointed out, No. 3 General Hospital arrived practically on the very day the railway was opened, and could not have been got up earlier. The Scottish private hospital arrived on the 27th of May, complete except as to some huts which were heavy and which arrived soon after, and it opened on the 4th June.

We do not think, looking at the position of matters, that blame can rightly be attached to the medical authorities for not sending up, before the railway was opened, doctors, trained orderlies, or nurses, in carts (as it has been suggested they might have done), even assuming doctors and trained orderlies to be available for the purpose. The fact that it was possible for a private individual like Mr. Burdett-Coutts to get up to the town with cart and mules does not, we think, justify an inference that it was practicable for the authorities to have sent up staff in this way.

As already pointed out from the evidence of Lord Roberts it is clear that the amount of sick and wounded at the time of the first occupation of the town was more than could have been reasonably anticipated.

The troubles at Kroonstad which we have pointed out were undoubtedly chiefly due to three causes—namely, the insufficiency in number of the field hospitals, the deficiency of the Royal Army Medical Corps staff, and the difficulties of transport.

JOHANNESBERG.

The army left Kroonstad on May 23rd and reached Johannesburg on May 31st. No great difficulties arose on the march and the Commissioners state that there was no lack of suitable buildings for hospitals and that on the whole the patients therein were well looked after. There was a good deal of friction at the hospital in the Victoria Hotel which somewhat hampered its working.

PRETORIA.

Pretoria was occupied on June 5th and the report says:—

When the British force first occupied this town on the 5th June the field hospitals accompanying it brought with them many sick and wounded. There were good buildings which were suitable for hospitals and there was no difficulty in procuring hospital necessaries and equipment in the town, or from Johannesburg, which was within easy distance. Steps were at once taken to prepare and equip some of the buildings, in which many of the patients were placed, but the equipment put in was in many respects deficient at first, and there was a delay of several days on the part of the medical authorities in remedying this deficiency. Moreover, the best building in the town, the Palace of Justice, was not taken for a hospital as quickly as it should have been. Surgeon-General Stevenson's explanation on this head is that he had, immediately on his arrival with the forces, considered the advisability of taking that building as a hospital, but thought he had sufficient other buildings available, and that there might be a difficulty in warming and ventilating such a large place, and he so informed Lord Roberts when the latter suggested its being taken. But on or about the 13th June the question was reconsidered. There is a little discrepancy between some of the witnesses on this subject as to how ultimately it came to be taken, but that is a matter of but slight importance. The essential fact is that shortly after the 13th June it was taken and equipped by the army medical and military authorities and the care of it was then committed by Lord Roberts to the Irish Hospital, of which Sir William Thomson was the chief surgeon in charge. That hospital had come on with the advancing force from Johannesburg and immediately on its arrival at Pretoria had pitched its tents on the racecourse, and had to keep, or take in and temporarily provide for, rather over 100 patients, whereas it was equipped at that time for only 50. It was originally equipped for 100 patients, but half of the staff had been left behind at Bloemfontein. For some few days, therefore, in this hospital on the racecourse only 50 patients could be provided with mattresses and stretchers to lie upon, the remainder of the patients having only their blankets and waterproofs. But Sir William Thomson, who was in charge, says that the weather was dry at the time and that no suffering ensued.

There is some difference of opinion amongst the witnesses as to whether or not other buildings might have been taken as hospitals as, for example, some of the hotels and churches; but having regard to the difficulty of warming, lighting, and staffing them we think on the whole that there was no want of judgment displayed by the medical authorities in selecting such buildings only as were in fact taken.

For some days after the first occupation of the town there were undoubtedly deficiencies experienced in the hospitals of many material things, and in particular of beds, mattresses, bed-pans, commodes, cups, and similar articles. For example, it appears from the evidence of Sir William Thomson and Mr. Murray Guthrie, M.P., that the Irish Hospital, which arrived on the 6th June, was for some days short, not only of mattresses and stretchers but also of change of clothing for the men, who had accordingly to be kept in their khakis, and that the men suffered in consequence.

As already pointed out, we think that many of these deficiencies might or should have been made good by the medical authorities earlier than they were, for the things required might have been obtained in the town or from Johannesburg, except such articles as bed-pans and commodes, which apparently could not be obtained at all.

There is some evidence to the effect of deficiency in respect of drugs, dressings, and blankets in the hospitals in the town, but on the whole we think that these articles were not wanting to any substantial extent, though in a few cases a deficiency was experienced for a short time. For example, there was a shortage of blankets in the 14th Brigade Field Hospital, owing to the number of sick that was sent into the hospital from the Boer prisoners and the British released prisoners, who had with them no blankets at all. Major Faunce, the principal medical officer of that hospital, was told by Surgeon-General Stevenson to purchase or otherwise obtain in the town such blankets as might be required, but finding that Mr. Murray Guthrie, on behalf of the committee which we shall presently mention, had bought up all the blankets in the place, he bought plushette, which he cut up and made into suitable coverings for the men. When the Palace of Justice was taken as a hospital a large supply of cots, mattresses, and blankets for it were obtained from contractors in the town. And after the lapse of about 10 days from the first occupation of the town Lord Roberts appointed a committee consisting of Mr. Murray Guthrie, Sir William Thomson, the Honourable Rupert Guinness, and Mr. Wood, who bought for the authorities and supplied to the hospitals most of the equipment which was then deficient. This committee sent a circular round to the various hospitals in the town informing the medical officers that any deficiency in their equipment could be remedied by application to the committee, and the hospitals appear to have availed themselves freely of the opportunity thus afforded.

For some time after the occupation of the town there was also an insufficient number of doctors and of orderlies, especially trained orderlies. There was also an insufficient number of nurses for a time, but we do not think that this state of things could have been remedied easily, having regard to the fact that the communications with the town were interrupted by the enemy and that there were considerable risks attending the transport of nurses. But the deficiencies we have mentioned were at any rate to a great extent made up directly the condition of the railway permitted fixed hospitals being transmitted, and on the whole we think there was no undue delay on the part of the authorities in regard to this.

On June 30th Surgeon-General Wilson arrived and brought with him a full supply of beds and other articles. Thereafter all substantial grounds of complaint ceased, and at the time we arrived in the town we found nothing concerning the care of the sick and wounded which could form fair or substantial matter for complaint.

Notwithstanding the temporary deficiencies after the first occupation of Pretoria above pointed out we are able to say that the condition of things there was much better than that existing at Bloemfontein and at Kroonstad after these places were first taken by the British. We believe that after a time no considerable hardships were endured by the sick and wounded in Pretoria and scarcely any complaints have been made with regard to their treatment.

Having regard to some of the evidence given we think it advisable to add a few words upon the sanitary arrangements in the town. There was no existing system of drainage and consequently, from this point of view, and for some time, the arrangements with regard to sanitation were not satisfactory. After a short period, however, Dr. Turner, the medical officer of health to the Cape Government, was consulted on the subject by Lord Roberts and authorised to deal with the sanitation, and under him matters were soon remedied. But previously to his appointment great need existed for a good expert sanitary officer to properly supervise the town and the camps, &c., and also to select proper and healthy sites for the troops to camp upon. This need of a good sanitary officer who should have authority, amongst other things, to select suitable and healthy sites for camps is shown by a statement made by Dr. Turner in his evidence that a very insanitary site was selected for the Welsh Regiment on its arrival which might have led, if it had not been changed, to considerable sickness being developed in that regiment.

After a few general remarks as to the care of the sick and wounded at the front the report goes on to consider the question of the conveyance of patients to and from fixed hospitals. With regard to this point the Commissioners say:—

Many complaints have been made, and many cases of hardship referred to, in connexion with the circumstances under which patients have been removed to and from the hospitals. We have already dealt to a certain extent with some of these cases under previous heads, especially with reference to patients being sent by convoys from the front. As already appears, beyond question considerable hardships had on many occasions to be endured by the men. Where the railway could be employed in their removal they naturally had to submit to comparatively few privations, but complaints are forthcoming with regard even to the train service. No doubt there are cases where inconveniences or even hardships have had to be endured by the sick and wounded conveyed by railway. The most severe cases, however, were always sent by the hospital trains when available. These were very well equipped and the men in them were well looked after. Others had to be sent in ordinary carriages and on occasions some convalescents had to perform the journey in trucks, owing, first, to the deficiency of suitable carriages, and, secondly, to the necessity of hurriedly relieving the congestion at the front, even at some risk to the men, as being the lesser of two evils. In these cases undoubtedly at times the patients must have suffered. An example is given by Dr. Jones, civil surgeon, of a convoy of convalescents arriving from Bloemfontein at Norval's Pont on the 10th June. These men had been 18 hours in open trucks on the way, some of them being convalescents from dysentery and enteric fever. The witness points out the deleterious effect the journey had upon them and states that one died five days afterwards from bronchitis. But though we cannot regard this as an isolated instance we have had the testimony of a great many patients who were conveyed by railway under various conditions, and we think that the cases in which such hardships as we have indicated were endured were not numerous and in most instances could not be avoided.

We have already dealt, under the head of Bloemfontein, with cases of ordinary railway carriages containing convalescents being sent down without the provision of proper blankets and how this was after a time remedied. We find complaints about similar cases where men were sent down without suitable arrangements for relieving themselves in cases of necessity between the stations; also statements as to the trains conveying them being occasionally foul and evil-smelling; as to the insufficiency of food during some of the journeys, and, in a few instances, as to want of attention to the patients at the intermediate stations during the journey. Cases of the kind no doubt did occur. Professor Chiene points out in his evidence how, in the matter of food, in the case of journeys by ordinary carriages, the patients' wants might have been relieved by placing a portable stove in the train, though this course did not apparently recommend itself to the medical authorities. But at most stations on the railway through which the sick and wounded had to pass the medical authorities provided medical comforts in sufficient quantities to supply the men, and before the men started on any journey they were, as a rule, well supplied with such comforts as well as with proper food. We have also already pointed out the existence of cases where, owing to the insufficiency of the medical staff, some convalescents or patients had to come down from the front without being accompanied by a medical officer or by trained orderlies; but these cases were not very numerous, and the men were generally able to a great extent to look after themselves, though, no doubt, there were individuals who suffered.

Speaking generally, though the hardships or inconveniences endured by some of the men in the cases above mentioned ought not to be made light of, we think, judging from the large number of witnesses who gave evidence on the subject, that as a rule the men were well looked after during their conveyance from the front, especially bearing in mind the conditions existing. This view of the case is supported by the fact that the mortality arising from these journeys was remarkably low, as appears from the following returns of the principal medical officer at the base (*vide* Appendix—*Supple* 1):—From commencement of the campaign to Sept. 1st, 1900: total number of sick and wounded sent down from the front in ambulance trains, 11,880; number of deaths in ambulance trains in transit, 14; number of deaths within two days of arrival at the base hospitals in ambulance trains, 20; total number of sick and wounded sent down from the front in ordinary trains, 10,867; number of deaths in ordinary trains in transit, *nil*; number of deaths within two days of arrival at the base hospitals in ordinary trains, one.

Touching the hospitals on the lines of communication the Commissioners say that there were not many complaints, but as regards Sterkstroom and Norvals Pont they find that there was good cause for the complaints. Sterkstroom at the time during which the causes of complaint arose was only a field hospital which had to be used as a fixed hospital. Concerning the deaths of three volunteers in the Kaffrarian Rifles the report says:—

As to one of these volunteers, a painful dispute arose with regard to his coffin, which it is not necessary for us to dwell upon. These deaths certainly occurred under very regrettable circumstances and formed the subject of much indignant comment in the local newspapers, and the correspondence relating to the subject was forwarded to the Commander-in-Chief. Without endorsing to the full the complaints against the hospital, still, after making allowances for the fact that it was only a field hospital, we are satisfied that its management and condition were not satisfactory.

NORVALS PONT.

The Commissioners say:—

The complaints as to the stationary hospital for some time after its opening show that its condition was far from satisfactory. It was deficient in bedsteads, bed-pans, commodes, feeding cups, basins, and similar articles, and according to some witnesses was lacking for some days in apparatus such as is to be found in well-equipped hospitals. For some time, also, this hospital had but few nurses or properly trained orderlies, and the attendance on the patients appears to have been accordingly somewhat lax. The deficiencies we have mentioned caused the inconveniences and hardships usually flowing therefrom. For example, the lack of sufficient commodes and bed-pans led to several enteric and dysenteric fever patients having to go long distances from their tents to the latrines, which were themselves not properly equipped or kept. It is right to state that the latrines were after some short delay moved nearer to the tents and were then properly provided with buckets, seats, and disinfectants.

BASE HOSPITALS AND HOSPITAL SHIPS.

These were satisfactory, even the much-abused Woodstock Hospital being in the opinion of the Commissioners suited to its purpose. There were bugs, but they did not materially affect the patients. Speaking generally of the base hospitals the Commissioners say:—

Base Hospitals Generally.

We need not dwell on the base hospitals (properly so called) in Cape Town or the neighbourhood, there being nothing in our opinion beyond what we have already stated which calls for special comment or forms just matter of complaint. These hospitals, or most of them, were visited by us, and with regard to each hospital as it existed at the time of our visit there will be found in the Appendix a short account prepared by our medical members (*vide* Appendix—*Church and Cunningham*). Speaking generally, the condition of these base hospitals appears to be well summed up by Colonel Cooper, the staff commander at the base, who visited the hospitals constantly at the time of greatest pressure. In speaking of the patients he says: "They were all housed and all had good mattresses to lie on, and were well looked after—much better than I have ever seen on service elsewhere." And in answer to the question: "Have you ever seen as much done for the sick and wounded as in this campaign?" he said, "Never. It was a revelation to me when I arrived here to go round the Wynberg Hospital." This favourable view of the base hospitals as a whole is corroborated by the fact that from the commencement of hostilities up to the 21st August last there were admitted therein 31,305 patients, and that only 362 deaths occurred out of this number, being an average of 1·15 per 100 (*vide* Minutes of Evidence—*Colonel Supple*). But there are some places in the neighbourhood of Cape Town which were not, properly speaking, used for the purposes of base hospitals, but which we may properly deal with under the present head. At these places some sick and wounded were tended, and much complaint has been made about their treatment, the complaint in our opinion being to a great extent made with good cause. We refer particularly to McKenzie's Farm and Maitland Camp, and they require some detailed consideration.

As regarding McKenzie's Farm and Maitland Camp they were neither of them intended for a hospital originally, and—

until McKenzie's Farm was changed into a hospital it was not, nor was Maitland Camp, suitable for the retention of sick men who ought to have been accommodated in proper hospitals, as in these camps they could not receive the full care and attention they needed. At Maitland Camp at one time for a few days matters were made worse by the illness of the civil surgeon there. The retention of sick men in these camps naturally caused suffering and formed the ground for substantial complaint. There were no proper beds for the sick and, of course, no nurses and for some time no properly trained orderlies. It is much to be regretted under the circumstances that the offer of Mrs. Wakefield to provide accommodation for the patients at Stellenbosch, to which we have referred, was not accepted by the medical authorities, as it would, at any rate to a certain extent, have relieved the pressure at the base hospitals and enabled some of the men detained in these camps to have been sent away. This was the more regrettable as in the camp at Stellenbosch, where at that time there was no hospital (though a good one was subsequently established there), some patients were being kept who ought to have been sent into a proper hospital and who had ultimately to be sent to McKenzie's Farm.

NATAL.

With regard to Natal the campaign there, so far as regards the sick and wounded, was conducted under much more advantageous circumstances than that in the Orange River Colony and the Transvaal. The railway was always available and therefore field hospitals did not have to be converted into fixed hospitals. The Commissioners proceed:—

To a great extent, by reason of the advantages above pointed out, we found but few substantial complaints about the campaign in Natal as compared with the campaign elsewhere. But the deficiency in the staff of the Royal Army Medical Corps at the outbreak of hostilities and the want of appreciation by the authorities of the forces necessary to carry the war to a successful conclusion were felt also in Natal. The army stationed in Natal at the outbreak of the war and which was first landed after war was declared came out with its proper units, that is to say, with its regimental doctors and with the field hospitals and bearer companies complete, but with no provision for base or general hospitals. As the army increased the difficulty was felt of providing a sufficient supply of doctors and properly trained orderlies and for a time there was an undoubted deficiency. Moreover, the general hospitals were not forthcoming as early as they should have been. But owing to a great extent to the energy displayed by the principal medical officers in Natal and the steps taken by them the deficiencies were made up with commendable promptitude. We may in particular refer to the evidence of Colonel Gallwey, Royal Army Medical Corps, as showing the good work done by that officer in Natal and as giving details as to the establishment there of the hospitals and the supply of civil surgeons, orderlies, men for the bearer companies, and nurses, details which we need not repeat in the body of this report. All necessaries for the sick and wounded were either obtained from the base or were bought promptly on the spot, though there was some delay in obtaining a sufficient supply of bed-pans and commodes. The Red Cross Society materially assisted by gifts of comforts. Speaking generally, we think that the sick and wounded in Natal were well cared for.

LADYSMITH.

In Ladysmith there was naturally a very great strain. Many of the medical officers broke down and at one time there were over 800 enteric fever patients and over 300 cases of dysentery, all of an aggravated type. There were only 69 in all of the Royal Army Medical Corps and of these 17 were in hospital at once, mostly suffering from enteric fever. The nurses exhibited much devotion.

HOSPITALS ON LINES OF COMMUNICATION.

The hospital at Pietermaritzburg was an old building and dirty. It was also overcrowded and understaffed at first. The linen was occasionally not properly washed.

As to the complaint that the principal medical officer in Natal had refused to form a convalescent camp, which was much needed, the Commissioners say:—

His critics appeared to be ignorant of the existence at the time they were referring to of a large convalescent depôt which had been established by him for 50 officers and 1500 men with all proper comforts and necessaries (*vide* Minutes of Evidence—*Colonel Gallwey*, Question 13,958). It was owing to the existence of this large convalescent depôt that when a small convalescent depôt was offered to him by certain local authorities, coupled with the condition that it should be staffed by the principal medical officer, he declined the offer, his reason being that he could more usefully employ his staff elsewhere. However, he offered to pay the local authorities for farming out convalescents at the rate of 4*s.* a day for privates and 6*s.* for officers and nurses, and this offer was accepted and the arrangement carried out. We do not think the principal medical officer can properly be blamed for his action in the above matters, nor do we think we need dwell upon a dispute which arose between the principal medical officer and some local authorities on a question whether certain refugees employed as orderlies should be clothed at the expense of the Imperial Government.

PART IV.

SUGGESTIONS WITH A VIEW TO REMEDYING DEFECTS.

These suggestions, which have already appeared in our issue of Feb. 2nd, are as follows:—

In previous parts of this report, and especially in Part II., we have mentioned several matters connected with the Royal Army Medical Corps as at present constituted, and the care of our sick and wounded, in which improvements are required. The extent to which, and the way in which, these improvements can practically be made, require detailed and careful consideration by military and medical experts. We recommend the appointment at some early convenient time of a departmental or other committee of experts to inquire into and report upon the steps needed to effect the following objects:—

1. The establishment of the staff of officers and orderlies of the Royal Army Medical Corps, and its equipment, on a scale sufficient to enable it to discharge adequately the duties ordinarily cast upon it in times of peace and by the smaller wars in which the Empire by its vast extent is so frequently engaged.

2. Regulations and provisions which will enable surgeons and trained orderlies in sufficient numbers to be rapidly obtained and added to the ordinary staff of the Royal Army Medical Corps in the event of a great war; and that will also ensure a rapid supply of all hospital and other equipment required for the due care of the sick and wounded in such a war.

3. The attraction to the Royal Army Medical Corps of a sufficient and regular supply of officers of good professional attainments. And the improvement of the position of the officers by the allowance of sufficient holidays; and by provisions enabling them to become adequately acquainted with the advancements in medical and surgical science; and the necessity of employing in the higher posts men selected for their merits rather than by seniority.

4. The employment, to a greater extent than that recognised and practised until the later stages of this war, of nurses in fixed hospitals for the care of the wounded and of fever and dysenteric patients, and such others as can properly be nursed by females.

5. The appointment of properly qualified officers of the Royal Army Medical Corps to undertake sanitary duties.

And with regard to other matters:—

6. The improvement of the existing ambulance wagons.

7. The selection and employment of the form of hospital tents best suited for the reception of sick and wounded in a campaign.

We also think that the committee might usefully consider the following questions, on which we ourselves express no opinion beyond what appears in Part II. of this report:—

(*a*) Whether it is advisable and practicable to some, and if any what, extent, that the Royal Army Medical Corps should have exclusive possession of and control over all necessaries for the sick and wounded (other than ordinary food and clothing, not being hospital clothing), so as to avoid the necessity of requisitioning upon the Army Service Corps or the Ordnance authorities.

(*b*) Whether the administrative and clerical duties of the principal medical officers can be lightened and in particular to what extent the reports and returns which have to be made can and should be shortened.

(*c*) Whether the men of the bearer companies, when not engaged on the field, could be employed to assist in the field hospitals, and whether with this object it is advisable that the staff of the bearer company and of the field hospital of a brigade should be under one chief officer.

(*d*) Whether in times of peace a regimental doctor should be attached to each regiment for some fixed time.

(*e*) Whether general hospitals could be advantageously divided into smaller units.

(*f*) Whether it is practicable and advisable that the reception and distribution of all charitable gifts for the sick and wounded should be by some organised body on their behalf; and if so, what that body should be.

The following are not matters for inquiry by the suggested committee. It will be sufficient if the attention of the Royal Army Medical Corps be specially called to what we are about to state, with a view to our recommendations being acted on.

Having regard to what we have said on the subject in Part II., we think that strict inquiry should be made in the various military hospitals in South Africa and proper steps be taken in order to stamp out, where it exists, pilfering by orderlies of the stimulants, comforts, or property of patients, and the receipt of bribes by orderlies from patients.

We also suggest that the officers should, so far as it is possible and consistent with due discipline to do so, relax the strict military rule generally adopted in military hospitals, so as to give an additional feeling of ease to the patients and enable them to better appreciate the comforts of a hospital.

The power and duty of every officer in this campaign in cases of emergency to buy for his hospital at the expense of the Government any necessary not in hospital and not procurable without delay elsewhere has been fully recognised by the authorities, and the power has been by many freely exercised. But, as we have already pointed out, some officers appear not to be fully acquainted with the existence of the power, and it is advisable that it should be made widely known that any exercise of that power will be favourably viewed by the authorities, unless, of course, in cases of its abuse.

ERRATUM.—In Part II. of our abstract of the Report of the Royal Commission on South African Hospitals which appeared at page 652, col. 2, in our issue of March 2nd, the word "Kimberley" in the paragraph commencing "The present article only deals with ....." should be "Bloemfontein."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6697 births and 4858 deaths were registered during the week ending March 2nd. The annual rate of mortality in these towns, which had been 19·5 and 21·2 per 1000 in the two preceding weeks, further increased to 21·5 last week. In London the death-rate was 20·9 per 1000, while it averaged 21·9 in the 32 large provincial towns. The lowest death-rates in these towns were 13·9 in Leicester, 14·1 in Oldham, 15·3 in Huddersfield, and 15·5 in Croydon; the highest rates were 25·4 in Halifax, 26·0 in Wolverhampton, 30·1 in Liverpool, and 38·2 in Plymouth. The 4858 deaths in these towns included 395 which were referred to the principal zymotic diseases, against 347 and 387 in the two preceding weeks; of these 129 resulted from whooping-cough, 109 from measles, 62 from diphtheria, 47 from diarrhœal diseases, 25 from "fever" (principally enteric), and 23 from scarlet fever. No death from any of these diseases occurred last week in Croydon; in the other towns they caused the lowest death-rates in Norwich, Halifax, Bradford, and Newcastle, and the highest rates in Bristol, Liverpool, Blackburn, and Sunderland. The greatest proportional mortality from measles occurred in Portsmouth, Liverpool, and Hull; and from whooping-cough in Plymouth, Bristol, Cardiff, Swansea, Derby, and Sunderland. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 62 deaths from diphtheria included 19 in London, seven in Sheffield, 6 in Birmingham, five in Bristol, and five in Salford. No death from small-pox was registered last week in any of the 33 large towns, and only one case of small-pox remained under treatment in the Metropolitan Asylums hospitals on Saturday last, March 2nd. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1823, against numbers decreasing from 2535 to 1834 on the nine preceding Saturdays; 185 new cases were admitted during the week, against 145, 142, and 162 in the three preceding weeks. Influenza was certified as the primary cause of 35 deaths in London last week, as compared with 12, 16, and 32 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 397, 420, and 493 in the three preceding weeks, further rose last week to 501, but were 58 below the corrected average. The causes of 72, or 1·5 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Leicester, Nottingham, and in 11 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Halifax, Sheffield, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·6 and 23·7 per 1000 in the two preceding weeks, further rose to 24·5 during the week ending March 2nd, and showed an excess of 3·0 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13·4 in Perth and 17·6 in Aberdeen to 27·0 in Glasgow and 28·3 in Dundee. The 768 deaths in these towns included 67 which were referred to whooping-cough, 23 to diarrhœa, 13 to measles, 12 to small-pox, four to scarlet fever, two to diphtheria, and one to "fever." In all, 122 deaths resulted from these principal zymotic diseases, against 106 and 99 in the two preceding weeks. These 122 deaths were equal to an annual rate of 3·9 per 1000, which was 2·2 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 33 and 36 in the two preceding weeks, further rose last week to 67, of which 43 occurred in Glasgow, 11 in Dundee, eight in Edinburgh, and three in Aberdeen. The deaths from diarrhœa, which had been eight and 16 in the two preceding weeks, further increased to 23 last week, and included seven in Glasgow, seven in Edinburgh, four in Dundee, and three in Aberdeen. The deaths from measles, which had been 25 and 19 in the two preceding weeks, further declined last week to 13, of which five were registered in Edinburgh, five in Aberdeen, and two in Glasgow. The fatal cases of small-pox, which had been 11, 20, and 15 in the three preceding weeks, further declined to 12 last week, and all occurred in Glasgow. The mortality both from diphtheria and from "fever" showed a marked decline from that recorded in recent weeks. The deaths referred to diseases of the respiratory organs in these towns, which had been 153 and 177 in the two preceding weeks, further rose last week to 184, but were 140 below the number in the corresponding period of last year. The causes of 40, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 34·3 and 33·7 per 1000 in the two preceding weeks, rose again to 46·6 during the week ending March 2nd. During the past four weeks the death-rate in the city has averaged 37·2 per 1000, the rates during the same period being 19·9 in London and 21·5 in Edinburgh. The 309 deaths belonging to Dublin registered during the week under notice were 85 more than the number in the preceding week and included 12 which were referred to the principal zymotic diseases, against 16, 10, and 11 in the three preceding weeks; of these, five resulted from whooping-cough, three from "fever," two from diarrhœa, one from measles, and one from diphtheria. These 12 deaths were equal to an annual rate of 1·8 per 1000, the zymotic death-rate during the same period being 1·6 in London and 3·7 in Edinburgh. The fatal cases of whooping-cough, which had been nine, three, and three in the three preceding weeks, increased to five last week. The deaths

referred to different forms of "fever," which had been five, two, and four in the three preceding weeks, declined again last week to three. The two fatal cases of diarrhœa showed a decline from the number in the preceding week. The 309 deaths in Dublin last week included 35 of children under one year of age, and 117 of persons aged upwards of 60 years; the deaths of infants corresponded with the number in the preceding week, but those of elderly persons showed a very large excess. 14 inquest cases and five deaths from violence were registered; and 122, or nearly two-fifths, of the deaths occurred in public institutions. The causes of 12, or nearly 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: H. L. Norris to the *Isis*, A. J. Laurie to the *Jason*, and T. H. Vickers to the *Alexandra*.

ROYAL ARMY MEDICAL CORPS.

Major J. G. Black is appointed to the charge of the Station Hospital at Devonport vice Major Wilson. Lieutenant-Colonel B. B. Connolly, A.M.S. (retired), is selected for appointment to the medical charge of the new Recruiting Depôt, New Cross-road.

THE DEBATE IN THE HOUSE OF LORDS.

It is some time since the House of Lords has been the scene of such an animated and brilliant debate as that which has been taking place during the present week in connexion with the relations of the military and civil branches of the War Office. The question raised by Viscount Wolseley as late Commander-in-Chief of the Army is one which may be termed a root question, because it goes down to the principles of constitutional government on a Parliamentary system. But it was, no doubt, the personal side of the controversy between his lordship and the Marquis of Lansdowne, the late Secretary of State for War, that gave rise to the extreme interest manifested and imparted a peculiar piquancy to the debate. It may be said that Lord Wolseley brought an indictment against a system; but Lord Lansdowne, in the course of his reply in its defence, preferred an indictment against the late Commander-in-Chief. There the matter ends for the present, but only for the present. What interests us, however, is confined within much narrower limits—namely, the side-light that it casts on the charges made against the medical service in South Africa. The debate shows one thing clearly enough—that the authorities at the War Office made all their preparations (which might have been, and probably were, good enough and even ample for the force originally intended and sent out) on far too small a scale as it turned out. As nobody seemed to have had any idea of the magnitude and enormous difficulty of the task which was being undertaken followed as a matter of course that the force originally sent out, and the medical, transport, and supply branches which went with it, proved quite inadequate.

SOUTH AFRICAN NOTES.

Lieutenant Forbes-Winslow, R.A.M.C., and Civil Surgeon Mowatt have much improved (Pretoria, March 2nd).

Civil Surgeons J. Stevenson, G. L. Hayden, and R. B. Williams have been discharged from Hospital to duty.

Major C. Stonham, Imperial Yeomanry Hospital, and Civil Surgeon F. Green are returning to England in the *Harlech Castle* which left South Africa on March 2nd.

Captain C. E Douglas, R.A.M.C., and Civil Surgeons J. C. Hibbert, T. W. Atkins, R. W. Collum, W. Tarr, and W. H. Rowell left South Africa in the *Manhattan* for England on March 2nd.

Major L. Haywood, R.A.M.C., and Civil Surgeons A. B. Dunne, V. W. Low, and P. E. Adams have arrived in England.

DEATHS IN THE SERVICES.

Major Henry Ernest Hill Smith, R.A.M.C., on Feb. 22nd at Cairo, aged 39 years. He served with the Dongola Expeditionary Force under Sir Herbert Kitchener in 1896, including the engagement at Firket and the operations at Hafir (mentioned in despatches, British medal and Khedive's medal with two clasps, and the Fourth Class of the Order of the Medjidie). He also took part in the Nile Expedition of 1897, and was present at the capture of Abu Hamed (mentioned in despatches, two clasps). In the Nile Expedition of 1898 he was present at the battles of Atbara and Khartoum (mentioned in despatches and promoted major, two clasps).

MEDICAL AND SURGICAL AID FOR SICK AND WOUNDED OFFICERS.

The first report of the Duke of Abercorn's Committee, dealing with the work done during the year 1900, is dealt with in another column of the current issue of THE LANCET. The report mentions that "no applications were received from officers of the Royal Navy or of the Volunteers, though it should be understood that all the advantages of the fund were equally open to officers of these services."

H.M.S. "BRITANNIA," DARTMOUTH.

In consequence of an epidemic of influenza on the training ship *Britannia* at Dartmouth the Admiralty, acting upon the advice of the medical officer in charge, have granted the cadets three weeks leave of absence, dating from March 2nd. There have been about 40 cases of illness, with two deaths from pneumonia.

Correspondence.

"Audi alteram partem."

INTERNATIONAL CATALOGUE OF SCIENTIFIC LITERATURE.

To the Editors of THE LANCET.

SIRS,—The formation of an international catalogue of scientific literature, which was initiated by the Royal Society and has been the subject of several international conferences during the last few years, has at last been started and cataloguing is in active progress. It is hoped that all papers published on and after Jan. 1st of the present year will be indexed; the indexes will be two in number—viz., an author index and a subject index. Each participating nation will be responsible for the indexing of the papers published in that country, and the indexing for Great Britain and Ireland is in the hands of a British bureau. A central bureau is to collect, coördinate, and publish the labours of the various national bureaus. I am writing this letter in order to make these facts known more particularly to medical authors and to invite their coöperation in making the venture a success. The various recognised journals for the publication of original investigations will be carefully searched, but it is possible that even the most conscientious and painstaking indexer may inadvertently miss an important paper, especially if it is published in journals or books which are not readily accessible. In order to guard against such omissions may I request authors to send separate copies of their publications to one or other of the following gentlemen who are responsible for the sections of the medical sciences appended to their names?

Anatomy.—Professor G. D. Thane, University College, London.

General Biology.—Professor E. A. Minchin, University College, London.

Physiology (including Pharmacology)—Dr. W. A. Osborne, Physiological Laboratory, University College, London, or to myself at King's College, London.

Experimental Pathology.—Dr. T. G. Brodie, Examination Hall, Victoria-embankment, London, W.C.

Bacteriology.—Mr. S. G. Shattock, St. Thomas's Hospital Medical School, London, S.E.

Experimental Psychology.—Dr. W. H. R. Rivers, St. John's College, Cambridge.

If authors are not able to forward actual copies of their papers, a note of place and date of publication, with full title of the paper, should at least be sent. Authors would considerably lighten the work of the indexers if they were also to send an index slip with their papers, indicating under two or three main headings the subjects of which their papers treat. Full details respecting the work and publication of the index could be obtained by writing to the director of the central bureau of the

catalogue, Dr. H. Forster Morley, 34–35, Southampton-street, Strand, London, W.C.

I am, Sirs, yours faithfully,
W. D. HALLIBURTON.

King's College, London, March 4th, 1901.

THE RECENT HUNTERIAN ORATION: THE EVOLUTION OF MAN.

To the Editors of THE LANCET.

SIRS,—Possibly you may find space to allow me to mention one or two difficulties which crop up in perusing the markedly interesting and important details brought forward in this year's Hunterian Oration[1] touching the origin of the human race and the sources and physical characteristics of the European sections; and I ask light not so much in regard to what we now are as whence and how we came to be man.

Assuming that man and the apes are derived from an identical or kindred stock, if I understand Mr. Macnamara aright his view is that the departure of the one branch from the common stock leading to man with his vast intellectual predominance over the other primates was rendered possible by a retarded closure of the frontal sutures permitting of the anterior brain growth and evolution, while in the anthropoid apes the sutures continued to close early in life, "the anterior part of their brain not increasing beyond the size it had attained at the end of the first year," and the explanation of this imperfect evolution of their frontal lobes lying to a large extent in "the premature ossification of that part of the skull which encloses the fore-brain." But granting that the line of structural changes was such, does not a more important question lie behind it, to the originating and guiding force which rendered possible this divergence from the hitherto prevailing rule? At the time at which these two sections of higher animal life commenced to diverge presumably the skull features in the one closely approximated those in the others; presumably the change was not accidentally brought about, nor by abnormal divergence, but by a gradual physiological process not common to the whole stock but limited to the one section and not potential then or at any subsequent period in the anthropoid apes; what, then, was the intrinsic power or extrinsic conditions which brought about the structural change which permitted the one section to advance to man and the absence of which retained the apes in the lower stage of being?

An innate faculty to respond to external natural demands, and an environment necessitating an increased brain and higher function of an intellectual character and the organ responding thereto, provide an apparently rational explanation, but to permit of it the bony cranium must accommodate itself to the altered brain conformation, either by accident or in physiological response to it. But, apparently, the view taken by Mr. Macnamara, while admitting an innate power of the brain "to develop and so meet the increased demand arising out of the struggle for existence," is that "the factors governing the growth of the skull differ from those which develop the brain," the brain not being dominant in the outcome, though the marked correspondence during the subsequent evolutionary steps of the human race between the osseous protection and the protected viscus indicate at least a clear coördinating power correlating both in structural advances if not an actual controlling influence of the brain in the skull conformation arrived at. Yet if this non-closure of the sutures in the man section of the primates is not to be found in an advancing brain organism, the osseous framework developing on lines independent of it, wherein lies the explanation of the anterior part of the anthropoid ape skull remaining a shut box controlling the size and function of its brain, while that of man has been permitted gradually to expand in conformity to an enlarging viscus not only endowed with higher intellectual powers, but with an additional speech faculty? Why the poor ape has been handicapped by the continuance of this common original structural defect which has clung to him ever since despite his surroundings, while man was freed from it and allowed to progress, is a mystery; nor is it easy to understand why, assuming that the line of progress has laid through a struggle for existence, the anthropoid apes escaped this struggle at the time when it operated to the advantage of the human family or since, or assuming that they have since been subjected to its influence why the same sequence of events has not again followed in their case as originally in man.

There is yet another point. The race of man has since developed two distinct cranial divergencies in altered relation of length and breadth, carrying with them corresponding brain peculiarities—dolichocephalic and brachycephalic. What relation do these bear to the original change? which was the dominant factor in the result—brain or cranium? and what was the cause in operation?

I write solely with the view of hoping to get cleared up knotty points in the chain of evolution of man, not as throwing any doubts on his probably common physical source with the lower primate order; to some it may suffice to know that he "is what he is," but to others the gradually unravelling past may be pregnant with hope touching his future; and among these latter I enrol myself.

I am, Sirs, yours faithfully,
FRANCIS H. WELCH, F.R.C.S. Eng.,
Surgeon-Colonel (retired), M.S.

Brandram-road, Blackheath, Feb. 25th, 1901.

PREGNANCY AND LABOUR COMPLICATED BY OVARIAN TUMOURS.

To the Editors of THE LANCET.

SIRS,—The valuable lecture on pregnancy and labour complicated with ovarian tumours by Mr. J. Bland-Sutton published in THE LANCET of Feb. 9th (p. 382), will serve the useful purpose of directing attention to an important subject which has been hitherto much neglected in the obstetric literature of this country. While in general agreement with the opinions he expresses and more especially as to the superiority of ovariotomy in labour where that is possible, I must take exception to his denunciation of reposition as a means of treatment. He characterises it as a measure "decidedly in opposition to all the canons of surgery." He founds this dictum on the two-fold proposition that "pregnancy exerts a baneful influence on ovarian tumours, and ovarian tumours are, as a rule, inimical to successful pregnancy." These reasons, though perfectly valid in regard to operation during pregnancy, are, it seems to me, irrelevant where an ovarian tumour blocks the pelvis during labour. It will naturally suggest itself at the outset that a woman in labour with an ovarian tumour in the pelvis presents an obstetrical rather than a surgical problem. In comparatively few of the published cases where reposition was effected would the circumstances have permitted the services of a skilled operator to be called in. Experience thus bears out the observation of Playfair that it is only exceptionally that expert attendance, with all the necessary appliances, can be had.

The great danger in these cases is delay, to which much of the mortality arising from this complication is to be attributed. This danger is well illustrated in the case which Mr. Bland-Sutton himself cites where, from the firm impaction of the head, it was found necessary to perform Cæsarean section before the tumour could be brought out of the pelvis. It will not be denied that this must add to the dangers of ovariotomy. Whether reposition was attempted earlier in labour is not stated.

On *a priori* grounds it would seem that to push the tumour out of the pelvis is a procedure comparatively free from danger and calculated to give immediate obstetric results quite as good as ovariotomy undertaken in unsuitable surroundings. *A posteriori* evidence confirms this view. In 41 cases in which reposition was accomplished six deaths followed, but three only can be fairly attributed to reposition, that is a mortality of 6·9 per cent. It is true that of several cases of ovariotomy performed during labour all have been successful, but all were performed by experienced operators and their numbers are still too few to justify dogmatic conclusions. A fairer means of comparison is to be found in the statistics which Dsirne has published of ovariotomy in pregnancy. Notwithstanding that the operations (135 in number) were in general undertaken under the most favourable conditions and with the strictest antiseptic precautions Dsirne found a maternal mortality of 5·9 per cent., little better than that obtained by reposition during the actual progress of labour.

I do not for a moment maintain that reposition is

entirely free from danger, but to found on one unsuccessful case an unqualified condemnation of a method which in the past has given such good results can scarcely be regarded as fair; indeed, the case which Mr. Bland-Sutton cites is, so far as I know, the sole published instance in which axial rotation followed reposition, with the doubtful exception of a case reported by Camden. Even should complications arise after delivery, though they do not seem to be more common in pelvic tumours that have been reposed than in the case of abdominal tumours, the statistics of post-partum ovariotomy show that they may be dealt with by operation with every prospect of success. Where, as must often happen, circumstances do not allow of immediate ovariotomy reposition is without doubt the best method of dealing with this dangerous complication of labour, as I have elsewhere shown,[1] and it will, I am convinced, continue to obtain the sanction of the most advanced obstetric authorities. It would, indeed, be as unreasonable to expect the general practitioner, under whose care most of the cases come, to advise an ovariotomy, which would involve dangerous delay, and expect him to advocate immediate operation in a case of strangulated hernia without first attempting reduction.

I am, Sirs, yours faithfully,

Aberdeen, Feb. 25th, 1901. R. G. MCKERRON.

"RETURN" CASES OF SCARLET FEVER: A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 23rd, p. 576, you referred to the recommendations made by the Royal College of Physicians of London to the Metropolitan Asylums Board that experiments should be made with a view to ascertaining in what way the tendency of patients to carry home infection from hospital can best be overcome. The suggested experiments are in the direction of a much greater classification of patients than has hitherto been practised, as regards the separation of complicated from uncomplicated cases, and of the complete isolation of cases for a short time prior to their leaving hospital. In view of the not very satisfactory results which, as recent statistics have shown, the hospital treatment of patients on the aggregation system has hitherto yielded, everyone, I think, will welcome any attempt to ascertain whether or not the methods hitherto practised are really the best. May I venture to suggest that the proposed experiment might with great advantage be carried further? Would it not be possible, in one or more of the hospitals of the Metropolitan Asylums Board, to set apart a considerable number of isolation wards (specially built for the purpose if necessary) for the separate treatment of patients or families of patients during the *whole course* of their stay in hospital—in other words, to try the effect of substituting true isolation for aggregation? There is reason to think, judging from the remarkable experience of towns where patients are treated in their own homes, that with such a method the percentage of septic complications would be lessened, the number of return cases reduced, and the patients could be allowed to return home very much sooner than is at present the case.

I am, Sirs, yours faithfully,

C. KILLICK MILLARD.

Town Hall, Burton-upon-Trent, March 1st, 1901.

CAMBRIDGE APPOINTMENTS ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—It will be a great kindness if you will once more draw the attention of qualified medical men who are graduates of the University of Cambridge to the Cambridge Appointments Association. We have an increasing number of applications for medical men to act in various capacities and would very gladly be of service to Cambridge practitioners who have the requisite qualifications. The amount of the subscription to this association (5*s.* per annum) is not large and no commission is charged in respect of appointments given or received. We have, therefore, no hesitation in asking Cambridge men who are qualified to join the association in order that we may extend its operations in the medical world. What is lacking at present is not appointments but men to recommend for them. We are in need particularly of those who have had special training in bacteriology as well as in other subjects, but we hope to be of service to others.

I am, Sirs, yours faithfully,

W. A. J. ARCHBOLD, Secretary.

73, Trumpington-street, Cambridge, March 1st, 1901.

[1] Transactions of the Obstetrical Society of London, 1897.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—Your able leading article on the above subject on Feb. 9th should lead the way to concerted action on the part of the profession by (1) the issuing of a largely and influentially signed statement pointing out in plain and truthful language the action on the organs of the body of excess in alcohol, particularly when taken in the form of spirit; and (2) the determination of each subscriber to the document to use his influence with his patients in correcting the false ideas that are current with the public as to the remedial and dietetic value of alcohol. Bands of Hope do much good by teaching the young the wisdom of avoiding the snares of drink, and temperance societies are a sort of continuation school for the youth as well as a means for reforming the drunkard, but the great mass of excessive drinkers are wholly untouched by these means. One of the greatest hindrances to true temperance is the virulent denunciation of the moderate drinker indulged in by some total abstainers. Intemperate speech will never promote temperance. By "moderate drinkers" I mean those who take habitually a moderate amount of light wine or beer with their meals and, as a rule, avoid spirits. If this standard were commonly followed there would not be one-tenth the present amount of drink consumed.

Very few people outside the medical profession have any idea of the havoc wrought by excessive drinking. The ordinary signs of excess are plain enough, but what the laity require instruction upon is the insidious and ever-increasing damage to the vital organs caused by over indulgence, especially when it takes the form of constant nipping. These facts must be urged on patients, alike in the hospital and the consulting room. It may be said that a medical man has not the time to take on the rôle of a temperance reformer. My reply would be an appeal to the spirit of true patriotism. The substitution of whisky for wine and malt liquors, which is so much the custom just now, is responsible for much of the chronic alcoholism so prevalent. The bugbears gout and rheumatism are a plausible excuse with many spirit-drinkers.

Societies, lectures, and addresses have had but little effect on the insobriety of the nation, and it is high time to adopt a man-to-man treatment, and the one to undertake it is the medical man. The late Professor Drummond has referred to the importance of individuals in carrying out great reforms as follows:—

> The past has, indeed, no masses. *Man*, not masses, have done all that is great in history, in science, and in religion. ..... We require to be taught again to-day to be content with aiming at units. Every atom in the universe can act upon every other atom, but only through the atom next it. And if a man would act upon every other man he can do so best by acting, one at the time, upon those beside him. The true worker's world is a unit. ..... Work with units, but above all work *at* units.

I am, Sirs, yours faithfully,

CHAS. W. CHAPMAN.

Weymouth-street, W., March 6th, 1901.

"THE COVENTRY DISPENSARY."

To the Editors of THE LANCET.

SIRS,—That "the heads of the profession" are the men who stand in the way of reform is proved by the action of some of the Birmingham consultants. Had the consultants been true to the profession the resolution lately passed by the Birmingham and Midland Counties Branch of the British Medical Association would have been a gigantic step in reform, but consultants by continuing to meet in consultation the dispensary staff are obstructing reform in a most audacious manner. The Birmingham consultants professed a very high standard of ethics when their own pockets were assailed by the Birmingham Consultative Institution and when they were loyally supported by the general practitioner, but when the interests of general practitioners are assailed these consultants, instead of giving a helping hand, are found in the camp of the enemy—i.e.,

bolstering up a condemned institution and encouraging the staff to set at defiance the mandate of the profession. The very men who did all in their power to compel Dr. Irvine to sever his connexion with the Consultative Institution are now doing all in their power to encourage the dispensary staff to serve a lay committee and to set at defiance the wishes of the British Medical Association and other ethical organs of the profession. Could anything be more despicable? "If the profession is true to itself" it will now treat those consultants with the contempt they deserve. Those who continue to support the Coventry Dispensary should be included in the same category as the dispensary staff and therefore "in future no professional recognition should be given to them." It will be very easy to discover the names of those consultants who continue to think more of the fees they get through the dispensary staff than of the good opinion of the profession at large. I was always taught to look upon consultants as the upholders of the honourable traditions of a learned profession, but from what I have seen lately I have come to the conclusion that they are greatly to blame for the degraded state of the profession. How can we general practitioners expect reform and expect our interests to be safeguarded when we find such men occupying the principal seats on the General Medical Council, on the council of the British Medical Association, and on the councils of our universities and colleges?

The resolution passed by the Birmingham branch of the British Medical Association has at least done one good thing by making the consultants show their hands. We see them now in their true colours and we can discern those that deserve the support of the general practitioner and those that deserve to be included in the "boycott."

I am, Sirs, yours faithfully,

Coventry, March 4th, 1901. J. LESLIE CALLAGHAN.

"'THE DUMMY CORPSE' CASE."

To the Editors of THE LANCET.

SIRS—I regret that in my letter on the above case I omitted to state that the temperature was taken from the mouth. Information as to the present condition of Browning can only be obtained by special permission of the Prisons' Commissioners.

I am, Sirs, yours faithfully,

GIDEON W. B. MARSH.

Tachbrook-street, S.W., March 4th, 1901.

THE ROYAL ORTHOPÆDIC HOSPITAL.

To the Editors of THE LANCET.

SIRS,—The report in THE LANCET of Feb. 23rd, p. 591, of the annual meeting of the above hospital held on Feb. 8th, will be clearer with the addition of some details which perhaps you will kindly allow me to furnish.

The honorary medical staff have always condemned the removal of the hospital to another site. Nevertheless, the former committee resolved to take that step and were contemplating the sale of the property for £28,000 when they were defeated on June 8th, 1899, by Mr. H. H. Marks. Lord Wantage (the president), Sir Walter Gilbey (the chairman), Sir Ernest Clarke, and other members of the committee subsequently resigned. The majority at that meeting was publicly acknowledged by Mr. Marks to have been obtained from votes specially created for the purpose. Later Mr. Marks became chairman and several of his friends were appointed members of the committee, while a near relative was made honorary architect. At the time of the meeting it was generally understood that the old committee had been defeated because they wanted to sell the hospital site. Soon after Mr. Marks and his friends came into power, however, they announced that they intended to sell the premises. No reasons were given for that sudden reversal of policy. The premises had been rendered sanitary at a cost of £2000 and the medical staff were still adverse to removal. The next steps were even more extraordinary. The value of the site, as given by Mr. Marks himself on Feb. 18th last, is £1500 at 30 years' purchase, or £45,000. The committee therefore proposed to sell their enormously valuable freehold property, their only asset, and to spend some £30,000 of the purchase money in building a new hospital on leasehold property in a slum. They were only prevented from that course by the unhesitating condemnation of their projected site by a sanitary expert.

On Feb. 18th Mr. Marks, by means of his following of votes, obtained from the governors full powers to sell the site. No financial details of any kind were, or ever have been, given. The alternative scheme for rebuilding on the present site was not discussed. The fact that the hospital premises consist of two blocks, one facing Hanover-square and the other Oxford-street, renders it easy to keep the hospital buildings at the Hanover-square end, and at the other to build two shops, with staff accommodation overhead. The rent from the two shops would be £800. To build such shops and rebuild the hospital is the alternative scheme. The argument that the site is too valuable to be retained as a hospital will not hold water. To deduct £30,000 from £45,000 is to leave £15,000 in hand. The £30,000 would be sunk in bricks and mortar and the remainder of the £15,000, after purchase of freehold and cost of removal, would be left in hand in lieu of the present splendid asset of the Oxford-street premises. Moreover, the larger new hospital in contemplation would mean a great increase of expenditure. In face of these facts it seems impossible that the Prince of Wales's Fund can have gone into the matter when they urge the sale of the Oxford-street site year after year.

The case seems to be on all fours with that of the Royal London Ophthalmic Hospital in Moorfields which sold the enormously valuable site near Broad-street and moved elsewhere. Their present bankrupt state is now the subject of heartrending appeals. Was their removal undertaken under pressure of the Prince of Wales's Fund? It is to be hoped that THE LANCET will look into this matter and see that arbitrary methods of company directors are not allowed to dominate the interests of an old-established medical charity. Lastly, one would like to know, as the Royal Orthopædic Hospital is a chartered institution, whether the Charity Commissioners will permit so unbusinesslike a scheme as the sale of the present freehold to be carried out.

I am, Sirs, yours faithfully,

London, Feb. 25th, 1901. A GOVERNOR OF THE HOSPITAL.

"THE ALLEGED DRYNESS OF AIR IN ROOMS WARMED BY GAS FIRES."

To the Editors of THE LANCET.

SIRS.—I see by an annotation in THE LANCET of Feb. 16th (p. 495) that Mr. Thomas Fletcher, F.C.S., attributes the unpleasant effects occasionally noticed in connexion with the use of gas-stoves principally to the escape of the products of combustion arising from defective flues. These unpleasant effects are not, however, confined to the use of gas fires, but are noticeable in most forms of close and independent stoves. Long ago it was suggested that this was due in a measure to the organic particles present in the air being decomposed when in contact with the highly heated metallic surface of the stove.

According to Sir John Leslie on Heat and Moisture, the moisture present in the external air is doubled by each increase of 27° Fahrenheit.[1] When air is artificially heated, therefore, and deprived of any means of absorbing the due proportion of moisture, the effect upon the lungs and skin of those subjected to its influence must be painfully apparent. Rapid evaporation and consequent reduction of temperature would naturally take place from all exposed surfaces, causing a contraction of the superficial blood-vessels, while those parts not so exposed would in consequence become congested. These ill effects are less apparent in those forms of gas fires adapted to the ordinary open fireplace. As, however, the object of most makers of gas stoves is the conservation of heat, the independent form of stove is the more popular with them.

I am, Sirs, yours faithfully,

Feb. 19th, 1901. A. C.

[1] Air at 32° F., for instance, contains $\frac{1}{150}$ of moisture, at 59° $\frac{1}{75}$, and at 86° $\frac{1}{38}$.

WEST CORNWALL MINERS' HOSPITAL, REDRUTH.—The annual meeting of the subscribers of this institution was held on Feb. 25th. The medical report stated that 150 patients had been admitted against 137 in 1899. The total cost per bed was £60 per annum. The financial statement was satisfactory and showed a favourable balance of £337. The secretary reported that the late Mr. W. P. Michell had left a legacy of a quarter of the residue of his property to the hospital which it was estimated would amount to about £7500.

THE ORGANISATION OF THE PROFESSION.

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 666.*)

Origin and Formation of the County of Durham Medical Union.—Strikes Hastily Organised and Insufficiently Supported.—Partial Successes and Partial Failure.—Extensive Importation of Outside Practitioners.—The Gradual Strengthening of the Medical Union.—Dissatisfaction with the Imported Opponents and Return of the Miners to their Former Medical Advisers.

THE first step taken towards the foundation of a medical union is always a matter of considerable practical interest. There are many medical practitioners scattered about the country who feel the necessity of organisation but do not know how to set to work so as to create a medical union. Any information as to the means which can be adopted for this purpose must therefore be of use. Sometimes it is felt that no one in the neighbourhood holds a sufficiently prominent position to be justified in assuming the leadership. In that case it is well if some old-established medical society can take the initiative; but it sometimes occurs that there is no such society available or that it is not disposed to move in the matter. More especially is this the case where the population is widely scattered, as in mining districts. Also the position and material circumstances of the colliery surgeon do not lend themselves to the participation of this section of the profession in the social gatherings and scientific discussions held by the old-established medical societies that exist in various parts of the country and which have their headquarters in the larger towns. The sense of isolation is certainly a strong deterrent to all forms of organisation and constitutes a serious obstacle to the formation of strong and well-disciplined unions among the rural practitioners and the colliery surgeons. These difficulties were undoubtedly present in the minds of the three practitioners who met together in the month of October, 1898, and resolved to make some effort to unite in one association all their colleagues practising in the county of Durham. For the moment it would be more prudent, I am told, not to mention the names of these three bold pioneers. Their names may be handed down to fame when the acuteness of the present struggle has worn itself away. For the present it will suffice to say that they all three practise in the north-east corner of the county, that they felt they had not sufficient personal influence to move the profession at large, and they very modestly entertained doubts as to their organising capacity. Nevertheless, they determined to make an effort and hit upon the very ingenious idea of asking a firm of solicitors to help them. They therefore requested Messrs. Graham and Shepherd, solicitors at Sunderland, to send out circulars to all the medical men practising in the county, urging the necessity of forming a medical union. Including in this appeal the town as well as the rural practitioners, this meant the distribution of more than 400 circulars. The fact that this was done by a firm of solicitors helped to inspire confidence. It could not be said that some particular medical man was seeking to push himself forward, assuming a leadership to which he had not been appointed. The fear also of blunders, of legal errors, was in a measure dispelled by the fact that a business-like firm of solicitors were engaged in the work. The formation of an association is, indeed, a very delicate matter. Here are, for instance, some 400 practitioners; if a few among them, six, or even a dozen, medical men, had formed a nucleus there might be ever so many personal objections to some or all these men. It is true that self-appointed committees, secretaries, or presidents only hold these positions *pro tem.*, and the society when definitely organised may elect other officials. In practice, however, this rarely occurs. It is generally felt, and rightly so, that those who have taken the first steps and done much arduous and unrequited work deserve to be elected as the permanent officials. Thus a personal impress is given to the society at its very birth; and if these personalities are not universally popular this is a source of weakness. Rather than go and vote against the self-appointed committee or secretary, and thus appear to be ungrateful, men who might have been good members stop away altogether. In this case, however, there was no secretary, no committee, no president, only a firm of solicitors who could not be looked upon as rivals by any of the medical men to whom they addressed the circulars. Thus, the personal rivalries, jealousies, and enmities which at the very onset constitute a formidable obstacle to the work of organisation were avoided. Consequently no less than half the practitioners who received this first circular replied in a sympathetic manner.

Encouraged by such widespread support Messrs. Graham and Shepherd sent out another batch of 400 circulars, inviting all the members of the medical profession to meet at the Freemasons' Hall in Durham on Dec. 8th, 1898, and there to discuss the advisability of forming a union. 51 practitioners were present and as everyone had been invited the meeting was sufficiently representative to take action. The proposal to form a union was adopted and Dr. Edward Jepson of Durham was elected its president. Then a council of 12 members was also appointed and the services of Messrs. Graham and Shepherd were retained as secretaries. The council was not only instructed to prepare a set of rules but was authorised to adopt them without convoking another general meeting. This work of organisation was rapidly carried out and terminated at a meeting of the council held on Jan. 10th, 1899, and from that date it may be said that the County of Durham Medical Union was definitely constituted. There was not much time lost before a move was made. Hardly was the medical union fairly in existence than a deputation was appointed to wait on the miners' leaders. The deputation consisted of Dr. Edward Jepson, President; Dr. J. F. Armstrong, Vice-President, from South Shields; Dr. C. F. G. Mann, from Washington; and Dr. J. Murphy from Sunderland. They were received at the Miners' Hall, Durham, by Mr. John Wilson, M.P., Mr. Johnson, the miners' financial secretary; Mr. Henry Cann, their treasurer; and others. Representations were made showing that 6*d.* per fortnight for medical attendance upon an entire family was insufficient. This sum was fixed some 50 to 60 years ago when the cost of living was much higher and the pay received by the miners was very inferior to what they are now earning. Under the present altered and more favourable circumstances the miners could well afford to pay 9*d.* per fortnight. On the other hand, the cost of medical education, of drugs, and of surgical instruments had greatly increased. The miners' representatives did not attempt to controvert any one of these statements. They simply explained that they had no power to deal with the matter. The miners were free to make whatever arrangement suited them best for medical attendance. Such questions should be negotiated with the men themselves or with whatever local organisation they might have established for the purpose of securing medical aid.

Thereupon the medical union at once prepared a letter which was forwarded on Jan. 26th, 1899, to every miners' lodge or organisation throughout the county, numbering in all 181. The letter inclosed a printed report of the meeting held by the members of the medical profession at which the question of raising the fortnightly subscription from 6*d.* to 9*d.* had been discussed and asked that the matter should be laid before the members of these organisations. If there were any objections the medical union would arrange for a deputation to meet the subscribers and discuss the matter amicably. This circular had been sent everywhere and not merely to those districts where the medical men had joined the medical union.

On March 2nd, 1899, the council of the County of Durham Medical Union met to discuss the answers received. From the 181 lodges, &c., only 42 replies had been received. The great majority evidently refused even to consider the proposal. Some desired to discuss with a deputation, as had been suggested; only a few accepted and undertook henceforth to pay 9*d.* instead of 6*d.* per fortnight. It was thus early rendered evident that the position of the profession was not to be improved, at least on a large scale, without a struggle, and perhaps a severe struggle. Consequently there would be victims, and therefore the first step was to make good provision so as to come to their assistance. A general meeting was convoked in Durham on March 7th, 1899, and it was then resolved to establish what was called an Indemnity Fund. So as to start this fund two medical men each subscribed £10 10*s.* Five others gave £5 5*s.* each. 14 practitioners promised to give 10*s.* weekly and seven put themselves down for 5*s.* per week. A circular giving these results was issued and it brought further subscriptions. It was decided that this fund should be administered by the President and the Vice-President only, so as to avoid unnecessary publicity. Members who were in need

of such assistance were requested to apply to the secretaries and to show their books establishing the loss they had experienced to the solicitors. They were assured that they would then receive every help, financial and otherwise. Those members who had obtained the increased rate of payment through the efforts of the union were urged to subscribe liberally; at the same time they were informed that they would not be called upon to fulfil their promises unless the money was really needed. This fund had barely been constituted when two practitioners had to be indemnified. In answer to their demand for the 9*d*. the miners had imported a medical practitioner who at first did all the work, and the two old-established practitioners found themselves without patients and without income. Fortunately, these imported practitioners rarely give satisfaction, and the miners gradually, one by one, came back to their old practitioners, so that the two practitioners who at first received financial assistance have now no longer any need for help from the indemnity fund.

Unfortunately, all the colliery surgeons had not the courage to hold out. Indeed, and as often happens in such cases, it was some of those who had been the loudest in clamouring for immediate action and in proposing a general strike who were the first to give way. They seemed to think that such contests are won by mere words and that the miners would yield at once. But the miners felt that if the medical men's cause was really a good cause it was worth fighting for, and if the medical men had so little faith in their own claims as not to fight for them then the miners need not trouble to make financial sacrifices on behalf of such milk-and-water individuals. The fact that there were a considerable number of week-kneed practitioners who mildly submitted to the refusal made by the miners rendered the struggle all the harder for those who had the courage to hold out. At Framwellgate Moor, at South Moor, and at Craghead, the colliery surgeons held out well. Opponents were imported, the colliery surgeons lost their patients, but still they persisted and the patients slowly returned to them. At the onset only a few medical men stuck to their point. There was no general battle but scattered skirmishes occurred, and when one colliery surgeon had won the day then some others in the neighbourhood would pluck up courage and enter the lists. Whenever the miners advertised for an outside practitioner to come and to establish himself in their district the County of Durham Medical Union immediately published counter advertisements in the same papers urging no medical man to accept these offers without first communicating with the secretaries of the medical union. This led to a great mass of correspondence; but, to the credit of the profession be it said, not a single one of the correspondents accepted the offers made by the miners after they had been informed of the true state of affairs. Thus the offers were only taken up by a class of men who find it difficult to get employment otherwise. That there is such a class is a fact that cannot now be denied and it is an important fact which must be dealt with. In the county of Durham alone some 20 such men have been imported.

The first annual meeting of the County of Durham Medical Union was held on June 6th, 1899, some six months after the definite creation of the union. It was then shown that 214 medical practitioners had adhered to the principles of the union and that 201 had paid their subscriptions as members of that organisation. As there are, in all, about 430 practitioners in the country, and as the union had not yet dealt with the interests of the town practitioners, this total of membership cannot be considered otherwise than satisfactory, at least for a beginning. The objects of the union are wide and far reaching, but so far the union has only attended to the one question of raising the subscription for contract work for the colliers. Unlike the Northumberland and Newcastle Medical Association, which is worked on the principle of centralisation, the rules of the county of Durham Medical Union admit the formation of district committees. It is true that the members of these local associations are to pay their annual subscription to the central body, but they are to be allowed by the general council any reasonable expenses incurred in carrying out the work of local organisation. At the first annual meeting it was stated that 10 such local committees had been formed and that the South Shields Medical Association had been affiliated to the County of Durham Medical Union. It was also reported that the colliery surgeons in eight districts had from the very first adhered to their notices demanding the increase. Strangers had been imported in seven out of these eight districts. At Southmoor five medical men had been imported, but only one remained; the others had left after a few weeks' experience of the unpleasantness of their situation. In the Stanley district the inaction of the majority of the local practitioners was a great source of weakness. Mr. Ingram-Johnson and Mr. S. J. Fox alone refused to accept less than the 9*d*., and they had to contend, not only against the importation of eight outsiders, but also against their colleagues and neighbours who were too timid to persist in the demand. At Washington also some of the local practitioners gave way, but Dr. Mann and Dr. W. Jacques held out manfully, though an opponent was imported to compete against them and is still in the district. Little by little the miners have individually returned to these practitioners and consented to give the 9*d*., so that these two surgeons have now gained back their former position, and in the course of time it will doubtless be considerably improved.

On Jan. 24th, 1900, a large general meeting of the County of Durham Medical Union was held. The union had then been in existence a full year, but complaints were still made of want of courage. The local committees were in dread of the family clubs organised by private practitioners and which could not be controlled. The report suggested that a minimum fee should be established for such clubs. On the other hand, the members present were cheered by the announcement that at Monkwearmouth 1400 miners were now paying the 9*d*. Five more collieries had been notified and four had got one practitioner from outside whom they shared between them, but he did very little harm. The Stanley district was again warned. Two practitioners had each received £50 from the indemnity fund, but there had been no other calls for such assistance. The employment of an unqualified assistant had been discovered by the council of the union and he had been denounced and had now left the county. It was urged that all members of the union should set a good example in this respect and not employ unqualified assistants. Canvassing which had been practised at Auckland was reported to the General Medical Council, but this body asked for affidavits which were difficult to procure. As the expenses had been very heavy it was found necessary to increase temporarily the annual subscription from half-a-guinea to one guinea. Dr. Alfred Cox of Gateshead gave a report in regard to a conference held at Newcastle during the previous month of November on the question of direct representation on the General Medical Council, with the result that the meeting passed the following motion:—

> That this meeting is of opinion that the medical profession is not sufficiently or properly represented on the General Medical Council and it is strongly recommended that all representatives from universities and corporations be elected by the individual votes of medical graduates of each university and members of such corporations.

During the ensuing month of March a circular was sent to all the practitioners of the county urging those who were not already enrolled to join the union and pointing out that at least 100 members had already had their incomes substantially increased by the efforts of that organisation. But it was necessary to deal, not merely with the contract work of the colliery surgeons, but also with family clubs, friendly societies, yearly boxes, midwifery fees, certificates, &c. In several places these questions had been taken in hand and with success. Soon after this, in June, 1900, the second annual meeting was held, when it was reported that success had been achieved in some more collieries, but that there was a prolonged struggle at Bishop Auckland and that the state of affairs in the Stanley district was still very deplorable. The imported practitioners had now departed from the Craghead district. At the Wardly Colliery district it had been difficult to get the colliery surgeons to act together. One of them was not a member of the union; nevertheless, the demand for the increase had been made and in reply a somewhat inoffensive opponent had been imported. In another district an imported practitioner had been compelled to appear before the General Medical Council to answer the charge of employing an unqualified assistant. Some districts still refused to give the increase and a few practitioners had suffered substantial loss. At Sunderland, South Shields, and Stockton the friendly societies had been approached with a view of improving the position of their medical officers.

All last year the work of organisation was continued and actively pressed forward. Throughout the President of

the union, Dr. Jepson, had been indefatigable, travelling long distances to interview recalcitrant practitioners, to attend local committees, or to address meetings of medical men so as to explain the action and policy of the union. Then there had been all manner of efforts made to get rid of the imported practitioners, and they, too, had been interviewed and many letters had been written to them. Of course, they were boycotted and none of the members of the union would meet them in consultation. Even the practitioners who were not members of the union joined in this boycott. If a second opinion was desired the imported practitioner must retire from the case. When the last annual meeting was held—and it took place on Feb. 5th, 1901—still further progress was reported. During the course of the year that had elapsed a considerable amount of important work had been done. In various districts, which at first had not joined in the movement, the members of the union were pressing for the increase and had met with at least partial success. It was strongly felt that the demand for the increase must be made at once while the high rate of wages still prevailed. There were very emphatic indications that the present state of prosperity would not last, and it would be very difficult for the colliery surgeons to obtain a rise in the face of a downward tendency in wages. At Hetton the local practitioners had been induced by the union to stand out for the increase and they had been entirely successful. Similar applications were made in the adjoining districts of Seaham and Silksworth, but one of the local practitioners hesitated to press forward his claim and preferred to renew his application at a later period. At Silksworth the colliery surgeon held out, and the colliery manager, acting in consequence of a notice he had received from the miners, determined that he would not retain any sum from their wages for medical purposes. The miners here threatened to form a medical aid association, but the local practitioners were striving to meet this by persuading individual miners to sign an agreement to pay the 9*d*. and arranging to have this sum collected independently of the colliery office. This had been so successful that out of 830 houses the inhabitants of 710 houses had accepted the proposal and were now paying the 9*d*. to a collector. It was suggested that this method of proceeding might with advantage be more generally introduced in other districts. At Crook strenuous efforts had been made to persuade an imported practitioner to leave, and though this was not achieved he was induced to raise his charge from 8*d*. to 9*d*. per fortnight, and therefore the members of the union were now competing with him on equal terms. Perhaps, however, the greatest event recorded was that the practitioners in the Stanley district had at last been brought into line. They had once again plucked up courage, made their demand, and this time stuck to it. The result was a complete success. A few malcontents were striving to get a practitioner to come to the district and to practise at the old rate of payment, and went about canvassing to secure adherents. Thereupon Messrs. Graham and Shepherd wrote and threatened them with legal proceedings, and this had somewhat damped their ardour. They had almost secured the services of an outside practitioner; but when the latter found that there was a chance of his being brought up before the General Medical Council for being in the service of an organisation that practised canvassing he promptly disclaimed any connexion with the concern. The members of the medical union who resided in the town of Sunderland, but who attended to patients who worked in neighbouring collieries, had also secured the 9*d*. and were now pressing similar claims on the friendly societies established in the town. In this latter direction some improvements had already been effected. The report presented at the third annual meeting then went on to say:—

> Our members will no doubt have noticed that attempts to form medical aid associations are in progress all over the country. This is a question that the General Medical Council ought to take up. They have already expressed disapproval of practitioners canvassing for patients and it is felt that they ought also to condemn and declare that it is infamous conduct in a professional respect for any registered practitioner to become the paid servant of any medical association formed and carried on by working men. The council intend, when sufficient evidence is obtained, to lay the facts before the General Medical Council and press them to take the matter into their consideration.

Such are the most salient facts connected with the history and development of the County of Durham Medical Union. Like all other movements, this union has had to learn by experience and has blundered from want of experience. There were at first over-confidence and a tendency to make efforts without due preparation and consequently they were not efficiently and strenuously sustained. The miners, on their side, complained that the medical men were lacking in tact in the way in which they opened negotiations. Some practitioners had a tendency to lay down the law and assumed a tone that unfavourably impressed the miners. After all, there were two sides to a bargain, and when some colliery surgeons declared that henceforth they were not going to do this or that, as if the decision rested entirely with them, the miners took the other view and thought that they also had a voice in the matter; and as there seemed to be no disposition to consult them they determined to act independently and to import medical men who would accept without question their terms. This feeling and attitude were not general, but they existed in some localities; and there could be no doubt but that some colliery surgeons were lacking in tact. They seemed to have forgotten that the miners, by the strength and discipline of their trade unions, had compelled the colliery owners to treat them on a footing of equality, and they expected to be treated by the medical men, whom they paid, with at least as much deference as was shown to them by the colliery owners from whom they derived their wages. But apart from this somewhat sentimental aspect of the question there was the material grievance that the miners did not get proper medical advice. Anybody seemed good enough to attend a miner when he was ill. Any unqualified assistant was sent to see the patient. Hardly any miners really object to pay the 9*d*. per fortnight or think the sum too large if they obtain in exchange careful treatment from a fully qualified practitioner, but they object to pay this sum if they are to be attended only by an unqualified assistant, and such unqualified assistants still exist in the county of Durham.

It will be seen from the above that the County of Durham Medical Union is quite in agreement with the miners on that question and that active measures have been taken to get rid of all the unqualified assistants. Under all these circumstances, and when time has rubbed off a few rough corners, there is every hope that both sides will come to terms amicably. The leaders of the miners—and I have lengthily discussed the matter with them—are really anxious to be on the best of terms with the members of the medical profession. There are mutual interests that should unite them. The Miners' Union give sick allowance to their members during illness, and it is therefore to their interest that malingering should be prevented and that the sick should be cured and return to work as soon as possible. On the other hand, the medical practitioners, if they do their best to insure these results, have the right to claim to be remunerated sufficiently. Thus with the abolition of the unqualified assistant, with a greater show of deference on each side, with a better understanding of each other's interests, peace may ultimately be brought about and the remaining contentions set at rest.

Durham, Feb. 25th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Epidemic.—The Famine Fund.—Hospital Ship for China.—The Queen Victoria Indian Memorial.

THE mortality from plague proceeds apace—declining in some places while it is rapidly rising in others. For the whole of India there were 3415 deaths last week, as against 3396 in the previous week and 1869 in the corresponding week last year. The chief increase has occurred in Bombay city, where the general mortality has risen to 1941, including 786 deaths from plague. This is a rise in one week of 320 plague deaths and of 522 in the general mortality. When it is mentioned that the normal mortality should not exceed, say, 500, the disastrous nature of the outbreak will be understood. This fifth outbreak looks as unfavourable as any that has preceded it. By comparison with previous charts it can be seen that the rising death-rate is proceeding on exactly parallel lines and indicates that there will be a still higher mortality for several weeks to come. In Bengal the total number of plague deaths has not increased, only 2129 deaths having occurred as compared with 2261 during the preceding week. Patna reports 1212 deaths, Saran 514, Mongbyr 245, Gya 36, and Calcutta 71. The outbreak in Calcutta is developing, more cases having

occurred in the quarter always first attacked, and a larger number of undoubted cases with a smaller proportion of suspicious deaths having been reported. Small-pox, however, is raging in the city and this caused 120 deaths last week. From previous experience elsewhere there is no evidence to show that this disease running at the same time effects any modification in the course of the plague outbreak. Elsewhere the disease does not indicate any marked virulence. More cases have occurred in Karachi which seem to herald an impending outbreak, and the plague has at last shown itself in Benares city. In many villages around it is still spreading. The Madras Presidency returns only 44 deaths, the North-west Provinces 14, the Punjab eight, and the Mysore State 269.

Famine in certain districts still continues. Some idea of the cost both to the Government and to the country has been previously published. The thirty-fifth list of subscriptions towards the famine fund has just been published and shows over 144 lakhs of rupees, equal to nearly a million pounds sterling. Assistance has been received from all parts of the world, which shows the sympathy of other peoples in probably the greatest famine that India has ever known.

The hospital ship *Gwalior*, which is maintained by the munificence of His Highness the Maharajah Scindia of Gwalior and which is estimated to have cost that prince £120,000, has sailed again for China. The following officers are in charge:—Lieutenant-Colonel A. M. Crofts, I.M.S., Lieutenant-Colonel W. Coates, I M.S., Captain Jay Gould, I.M.S., and Lieutenant G. Tate, I.M.S. Reliefs are being taken out, and it is hoped that the *Gwalior* will be able to bring away the sick and invalids from Peking which the *Carthage*, recently returned, was unable to do owing to the rivers being frozen.

An Indian memorial to Queen Victoria is contemplated and the support it has already received is unparalleled. Before a meeting was held or a subscription list opened nearly £200,000 were promised. It is proposed to erect a magnificent hall on the north end of the Maidan of Calcutta and to surround it with gardens. This will be the national memorial and it is fitting that it should be placed in the capital. Other cities are already arranging to have memorials of their own. Some of the princes of India have already shown their loyalty by a splendid munificence, the Nawab of Dacca having promised Rs.50,000, the Maharajah of Gwalior Rs.1,000,000, the Maharajah of Kashmir Rs.1,500,000, and the Maharajah of Jeypur Rs.500,000.

Feb. 9th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Progress at the Manchester Royal Infirmary.

THE admission of women students to the wards of the Manchester Royal Infirmary would have been scouted 50 years ago as revolutionary and worse. Now, however, the change is made without exciting surprise or feeling and the matter occupies just three lines of the report of the infirmary that has just been issued: "On the application of the Council of the Owens College and with the concurrence of the medical staff it has been decided to admit women students to the hospital practice of the Infirmary." A second important and wise decision has also been arrived at. The report says: "Your board have come to the conclusion that it would be desirable in the interests of the institution that the honorary staff should be more intimately connected with its management." Four of the staff being trustees—i.e., being subscribers of three guineas or more annually—may be elected annually by their colleagues to serve on the board of management. The question of rebuilding on the present site or removing the infirmary is also apparently settled in favour of the former and has so far advanced that plans and estimates are now being obtained.

Crusade against Tuberculosis.

Dr. Harold Coates, the special medical officer employed by the city council to assist in the crusade against tuberculosis, has been making investigations as to the infectivity of the dust found in the dwellings of tuberculous patients. The samples were collected with strict aseptic precautions. The dust was mixed with sterilised water and was then used to inoculate guinea-pigs. In many cases the animals died within 48 hours from septic disease due to germs other than the tubercle bacillus. The others were killed a month afterwards; post-mortem examinations were made, and where tuberculous lesions were found microscopical preparations were made and the bacilli were demonstrated. The houses examined were divided into three classes: 1. Dirty houses, where consumptive patients take no precautions to dispose of their expectoration so as to prevent infection of the atmosphere. Of this class 23 were examined. 2. Very clean houses, but where consumptive patients were living who were not sufficiently careful. 10 of this class were examined and in five—i.e., 50 per cent.—infective dust was found. 3. Very dirty houses in which there had been no case of tuberculosis for some years past. A number of houses, all very dirty, but where there was a clear history that no case of tuberculosis had occurred for three years or more, were selected, and in no case was infective dust found in them. It has been the practice of the Manchester Hospital for Consumption for several years past, with the coöperation of Dr. Niven and the health department of the corporation, to have the houses of the patients disinfected, for it was found that many of these patients who were apparently cured became re-infected on returning to their homes. The plan adopted in Manchester is that of disinfection of walls, floors, ceilings, furniture, &c., by washing with a solution of chlorinated lime, one and a half ounces to the gallon, which is found to be thoroughly efficient. The importance of precautions in the disinfection and disposal of expectorations is by now becoming known to the more educated portion of the community, but there is a great amount of apathy and ignorance among those who form the bulk of the out-patients of the hospitals.

Typhus Fever in Ancoats.

Since Dr. Niven's first report to the sanitary committee of the Manchester City Council 25 more cases of typhus fever have broken out. So far as ascertained the total number amounts to 60. Nine of the patients who were removed to hospital have died. It seems that most of those "by whom the disease has been introduced into households or by whose instrumentality the disease has been spread" have been rag-sorters or tobacco workers. But the original cases have been traced beyond them and the connexion is now considered doubtful between these trades and the outbreak. Meanwhile the outside source of infection has not been discovered. There is nothing in the work of the tobacco factory to aid in the spread of the disease, "and it is possible that the large number of cases occurring in this occupation and in the sorting of rags is due rather to the poverty and wretched homes of the workers than to the character of the work," but the possibility of its spread from rags or tobacco has been taken into account and preventive measures have been taken. Dr. Niven expresses himself indebted for assistance and counsel in dealing with the outbreak to Dr. C. H. Braddon, the chairman of the hospitals sub-committee.

The Owens College Jubilee Memorial Fund.

The fiftieth anniversary of the opening of Owens College will occur on March 12th. It is unnecessary to say anything as to the important work that has already been done by the College for higher education, not only locally but through the country at large. Since it was founded other university colleges have sprung into being, as at Birmingham, Bristol, Leeds, Liverpool, Newcastle, Nottingham, and Sheffield, having had their origin, Manchester may claim, to a great extent in the example set them in Manchester But the growth of the College and the extension of its work involve financial necessities, and it is proposed to commemorate this Jubilee year by raising an endowment fund equal to that bequeathed by John Owens. This means at least £100,000. Another sum of £50,000 is to be raised so as to clear off debts and "to repay the deficit on income account in past years." The largest of the debts is £22,000, "the balance of the sum which was required to complete the buildings of the Medical School on a scale commensurate with its high rank among the medical schools of the kingdom." Already five sums of £5000 eacn have been promised and it is hoped that the remaining large sum will be obtained without any extraordinary difficulty. The appeal draws attention to the large amounts raised in America for educational purposes, it having been computed that since 1883 at least £22,000,000 have been given by private citizens (apart from State aid) to promote advanced education in their country—an example to be followed, it may be hoped, by some of the wealthy Lancashire people.—At the half-yearly meeting of the Court of Governors, held on March 5th, the appointment of Dr.

R. B. Wild to the Leech Professorship of Materia Medica and Therapeutics was confirmed.

The Port of Manchester.

A meeting of the Manchester Port Sanitary Authority was held on March 4th. The medical officer's report showed an absence of serious sickness on the 93 vessels which had entered the port since the last meeting. Dr. J. H. Crocker is leaving for Richmond, where he has been appointed medical officer of health, and his resignation has been accepted with regret. In this, his final report, he says that he "had never felt quite sure that some cases of plague or small-pox might not escape him owing to his inability to be present at the arrival of every vessel." Fortunately, no case of plague has escaped him, and, indeed, a most assiduous watch has been kept up. He stated that it was advisable to appoint a medical officer who should devote the whole of his time to port sanitary work, and as his time would be fully occupied at Manchester it would be necessary to arrange for deputies at other parts of the port. Rats were mentioned as a great source of danger, and it was suggested that the ships should be kept four or six feet from the quay and the ropes guarded to prevent the rodents from swarming upon them. In all ships the rats should be exterminated and in the warehouses, too. After some discussion it was agreed "to advertise for a medical officer to devote his whole time to the work outlined in the report, the salary to be £350 a year." This gentleman must, of course, be well qualified, must have a diploma in public health, and must be always on the alert, for his responsibilities will be great and constantly increasing with the increase of traffic, so that the salary proposed does not err on the side of liberality.

March 6th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Infirmary: Local Public Spirit.

THE annual meeting of the supporters of the Cardiff Infirmary has of late years been a gathering at which the single story has been told of increasing expenditure and lessening income with the natural accompaniment of a standing debt mounting higher and higher. Year after year suggestions have been made for lessening the expenditure or for increasing the income of the institution. Wards have been closed and small economies have been effected, while bazaars, balls, and concerts have been organised for the purpose of reducing the adverse balance. In spite, however, of every effort the amount of indebtedness increased until at the beginning of the year 1900 it stood at £10,700 and although there was an increased income during the year of £825 and a decreased expenditure of £612 the executive committee managed to spend £633 more than they received. At the end of 1900, therefore, the standing debt was £11,333. The decrease in the expenses is attributed to the closing of the special gynæcological wards which contained 30 beds and were opened three years ago. The reduction of the number of beds in the infirmary constantly available from 150 in 1899 to 120 in 1900 is said to account for the increase in the annual cost per bed from £54 5*s.* in the former year to £63 15*s.* in the latter. It had long been felt that only by a great effort, and one which was supported by the leading men in the town, could the institution be cleared of its incubus, so that when the newly elected mayor (Mr. T. Andrews) announced on Nov. 9th last that he was determined to wipe out the debt brighter prospects seemed in store. Although subscriptions, some of considerable sums, came in rapidly in response to the mayor's appeal it is doubtful if he could so speedily have achieved his purpose without the assistance of one of the Cardiff daily papers, the *Western Mail*, the managers of which inaugurated a "shilling fund" and placed at the head of it their own munificent subscription of 500 guineas. In a little over three months, at the annual meeting on Feb. 27th, the mayor was able to hand over a cheque for £11,272, a sum which was practically sufficient to extinguish the debt and which included £5697 sent to the mayor's fund, £5375 sent to the *Western Mail*, and £200 sent to a fund established by the Mayor of Cowbridge, a small town which is joined to Cardiff for Parliamentary purposes.

Refuse Destructors.

The large towns in South Wales have been slow to adopt the methods of refuse destruction which have for many years been employed in other parts of the United Kingdom, notably in the manufacturing towns of the north of England. At Cardiff, at Swansea, and at Merthyr house refuse is still carted out to large "tips" in the suburbs of those towns. In the Rhondda valley there is approaching completion a destructor of the type known as "Mason's gasifier," which appears to have recommended itself to the sanitary authority in consequence of the small chimney which is required, a factor that can be appreciated in those localities where the refuse to be destroyed cannot readily be brought to a central depôt, but has to be dealt with in different parts of the district. At Barry a destructor was formally started on Feb. 27th and is actually the first to be erected in South Wales. It is of the Beaman and Deas type and consists of two cells which are said to be capable of burning 30 tons of refuse per day of 24 hours. The entire cost of the installation is £7500.

Pembrokeshire and Haverfordwest Infirmary.

The annual report of this institution states that during the year 1900 there were treated 99 in-patients and 673 out-patients at a cost of £869. The total income for the year from interest upon investments and from subscriptions amounted to £860. It is anticipated that the alterations in the drainage, &c., which are now being carried out will be completed and will permit of the wards being reoccupied by the beginning of May.

The Medical Officers of Health of Haverfordwest.

Mr. George Griffith has resigned his appointment as one of the four medical officers of health for the Haverfordwest rural district. The population of the whole district is about 32,000 and the area 160,000 acres. Each of the medical officers of health receives a salary of £20 per annum.

Public Health Laboratory at Cardiff.

The Cardiff and County Public Health Laboratory has been established nearly three years, and the increasing usefulness of the undertaking is demonstrated in the report of the bacteriologist (Dr. W. G. Savage) for the year 1900. Three suspected cases of plague were bacteriologically investigated during the year—two with a positive and one with a negative result. For suspected diphtheria 243 specimens were examined and in 72 instances Klebs-Löffler bacilli were found; Widal's reaction occurred in 73 specimens examined and tubercle bacilli were demonstrated in 36 of the 86 specimens of sputum examined. There were bacteriologically examined 119 samples of water and 198 additional samples were submitted to chemical examination. A small fee is paid by medical practitioners or medical officers of health who forward material for bacteriological examination, but all samples of water sent by medical officers of health within the administrative county are examined both bacteriologically and chemically free of charge.

Royal West of England Sanatorium, Weston-super-Mare.

The annual meeting of the subscribers of this institution was held on Feb. 23rd. The medical report stated that 2120 patients had been admitted during 1900—an increase of three as compared with the previous year. 8462 hot and cold sea-water baths had been given and had afforded much relief in rheumatism. The financial statement showed that the total income for the year was £3788 and that the expenditure amounted to £3471. Mr. F. J. Fry was re-elected president.

Exeter Dispensary.

The annual meeting of the governors of this institution was held on Feb. 23rd. The medical report stated that 5571 patients had been treated during 1900, against 6256 in 1899. The financial statement showed a favourable balance of £212. The chairman (Mr. S. Ward) said that by a rule of the dispensary members of clubs who were entitled to medical treatment and medicine were not eligible as patients.

March 5th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Edinburgh.

As was to be expected several fresh cases of small-pox have shown themselves in Edinburgh. At the date of

writing there are four cases in hospital. The public are not yet, however, sufficiently alarmed to seek revaccination to any great extent. A circular has been issued by the Local Government Board to local authorities, recommending the coöperation of the local authorities of county districts with those of burghs and the prompt establishment of small-pox hospitals and houses of reception, while it also refers to the power now given to local authorities by the Public Health (Scotland) Act, 1897, to offer free vaccination when such appears necessary.

Edinburgh Royal Infirmary.

A meeting of the managers of the Edinburgh Royal Infirmary was held on March 4th. Dr. D. Berry Hart was appointed gynæcologist, in room of Dr. J. Halliday Croom whose term of office had expired. Dr. Croom was appointed honorary gynæcologist to the institution. The quarterly financial statement was presented by the convener of the house committee, being the accounts of expenditure and revenue for the quarter ending Dec. 31st, 1900. This statement showed an increase in the quarter on the ordinary expenditure of nearly £1000. In maintenance there was an increase of £140 1*s.* 5*d.*; in medical expenditure, £57 11*s.* 9*d.*; in wages, £235 1*s.* 7*d.*; in coal and dross, £624 11*s.* 9*d.*; in lighting, £106 11*s.* 4*d.*; in salaries, £155; and in taxes, fire-insurance, &c., £31. The increase in most of those departments was due to a rise in the price of articles bought. The total ordinary expenditure for the quarter had been £13,526 10*s.* 4*d*, so that at that rate the infirmary would cost at least £1000 per week, or over £54,000 in the year. Mr. Blair pointed out the necessity of encouraging the public and others to increase their subscriptions and donations. It was arranged that a private meeting of the managers should be held to examine the accounts.

University of Edinburgh.

The Senatus Academicus has offered the honorary degree of LL.D. to (among others) Dr. James Little, Regius Professor of Physic, University of Dublin, and to Sir John Williams, Bart. At a meeting of the Edinburgh University Court held on Feb. 18th the Senatus reported that the Faculty of Medicine had appointed Professor A. R. Simpson to be Dean of the Faculty in room of Professor T. R. Fraser, who had resigned that office. The court approved of various grants, recommended by the Senatus, from the Earl of Moray Endowment Fund for the following researches: 1. Research by Dr. J. M. Beattie on the Origin, &c., of Cells in Inflammation. 2. Researches by Mr. Nelson Annandale in the Malay Peninsula. 3. Researches by Dr. J. H. Ashworth on Marine Worms. 4. Research by Dr. Beard on the Development of the Elasmobranch Fishes. The court granted the application for recognition by Dr. Alexander Bruce, Edinburgh, as a lecturer in medicine. It was agreed to accept with thanks the sum of £200 offered by the Scottish Association for the medical education of women and subscribed for the foundation of a prize for women students of medicine in memory of the late Janet Dorothy Gilfillan, M.B., Ch.B. Edin.

The Glasgow Small-pox Epidemic.

The report issued on March 1st announced that during the past week 130 new cases had been admitted to hospital, 90 patients had been dismissed well, and 10 deaths had occurred. The number of patients remaining in Belvidere on March 1st was 385, an increase of 30 on the previous week. This record has produced great disappointment and something like consternation in the city. The recent announcement of the discontinuance of the daily bulletin had produced a general impression that the worst of the epidemic was passed and that there was no longer any need for anxiety. But it is now recognised that these favourable anticipations were ill-founded and the tension of public feeling has correspondingly increased. Apart from the serious features of the epidemic as painful and serious facts, it is keenly realised that the existence of small-pox in the city on so extensive a scale is likely to exert a most prejudicial effect on the success of the forthcoming exhibition, and this feeling has found expression in the public press. With a view to allay public anxiety the Lord Provost on March 3rd received and made a statement to the chief reporters of the local newspapers. His lordship announced that 20 additional inspectors had been appointed and that the whole time of the inspectors was to be devoted to house-to-house visitation with a view to discover unvaccinated persons and to press on all the necessity of revaccination. In his weekly report the medical officer of health draws attention to the large proportion of adults among the patients as showing that it is those who neglect revaccination who keep small-pox active in the city. He also alludes to the influence of a fall in the number of cases on the practice of revaccination. The number of revaccinations reported during the past fortnight reached a total of 77,562, but judging from the amount of lymph given out during the last few days there has been considerable less activity in this direction. The mild cases of the disease, which are often regarded as chicken-pox or "spots" caused by "indigestion," cause the health department much trouble, as they are both difficult to discover and produce numerous "contacts" which it is impossible to trace. As indicative of the popular feeling the *Glasgow Herald* calls for the appointment of a special commission consisting of leading physicians and representatives of the health authorities. It also proposes the mapping out of the city into some 150 districts, each to be put in charge of a medical officer and a lay assistant. There is certainly a need for energetic measures if the city is to be made safe for its inhabitants and attractive to visitors. This claim has all the more urgency in view of the approach of the months which provide the seasonal conditions that favour the spread of small-pox. Dr. A. K. Chalmers warns the public that there is need for increasing apprehension if the apathy in reference to revaccination which has recently manifested itself is allowed to continue.

Faculty of Physicians and Surgeons of Glasgow.

Dr. A. K. Chalmers and Dr. Robert S. Thomson having passed the necessary examinations have been elected Fellows of the Faculty. Dr. Robert Muir, Professor of Pathology in Glasgow University, has also been admitted to the Fellowship.

Medical Appointments.

Mr. David Chalmers has been appointed casualty surgeon to the Glasgow Southern Police District. Dr. E. A. Gibson has retired from the position of obstetric physician to the Glasgow Training Home for Nurses, his term of office having expired.

Scottish Special Hospitals.

The fifteenth annual report of the Glasgow Samaritan Hospital for Women gives evidence of the increasing usefulness of this charity. The pressure on both the in-patient and out-patient departments has become so great that the directors have been compelled to consider the possibility of increasing the hospital accommodation. They propose, therefore, to build a new wing to provide 20 beds and two operating rooms at an estimated cost of £7000. Towards this sum the trustees of the Bellahouston bequest have generously contributed £1700 and the directors now appeal to the public to subscribe the balance, at the same time intimating their intention not to commence building until the greater part of the sum needed has been promised. The report gratefully acknowledges the gift of a convalescent home by a lady who desires to remain anonymous.—The annual meeting of the subscribers to the Glasgow Cancer and Skin Institution was held on Feb. 26th, and the chairman, in moving the adoption of the report, announced that it would be necessary, in view of the increased demands for admission, to contemplate the enlargement of the hospital at an early date. The vote of thanks to the medical staff was proposed by Dr. David Yellowlees who paid a high compliment to the excellence of the work of the institution both in the wards and the laboratories.—At a recent meeting of the subscribers to the Paisley Eye Infirmary it was announced that Mr. Kenneth M. Clark had presented to the institution a complete outfit of instruments at a cost of £500.

Scottish National Red Cross Hospital.

The staff of this hospital have determined to celebrate their associated work in South Africa by holding an annual dinner and the first meeting took place in Glasgow on March 1st. The chair was taken by Mr. J. Luke, in the unavoidable absence of Mr. Henry E. Clark, senior surgeon. The other members of the staff and a number of medical students who acted as dressers were also present. In the course of the evening the chairman presented to the members of the hospital burgess tickets constituting them freemen of the City of Glasgow.

March 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Cullen Case.

WHAT has been known as the "Cullen case," has caused much interest in Dublin for a period of many months and has been the subject of much comment in the press. It will be remembered that an outbreak of enteric fever took place more than a year ago at the north side of Dublin which was traced to infected milk supplied from a dairy situated in the Castleknock district, the proprietor of which suffered from that disease. The Local Government Board held an inquiry, and although the resident medical and sanitary officer declared that he was not aware that his patient owned a dairy, the Board after full investigation decided on calling for the resignation of the two officers of the corporation who had neglected to inspect or register it, and of Mr. J. J. Cullen, the dispensary medical officer, who had omitted to notify the case. The latter tendered his resignation, but the board of guardians declined to accept it and appointed him to do the medical work of the district as "locum-tenent," a position which he has held for many months and up to the present date. On August 10th, 1900, the Local Government Board applied for a conditional order for a mandamus directed to the guardians of the North Dublin Union ordering them to elect a duly qualified person in the place of Mr. Cullen. On August 15th, when an application was made by the guardians for an extension of time to enable them to show cause against the conditional order, Mr. Justice Barton said that the motion ought to be heard by the full court. He said that there could be no more important case than this, in which a great department of the State was in conflict with one of the elected representative bodies of the country. Therefore it ought to be heard by the full court, and their decision should be accompanied with all the authority which a court of justice could give to a case of this kind. Accordingly, on Nov. 29th the application of the Local Government Board for Ireland against the Board of Guardians of the North Dublin Union was heard in the Queen's Bench Division before the Lord Chief Baron, Mr. Justice Andrews, and Mr. Justice Boyd, the arguments being sustained by a full representation of the Irish Bar and occupying two days. On Dec. 10th the Lord Chief Baron delivered the judgment of the court and said that the conditional order for a mandamus would be made absolute. The merits or demerits of Mr. Cullen's conduct were not considered and were pronounced to be inadmissible, the decision of the court, as the Lord Chief Baron stated, being based on purely legal and technical grounds. He said that the Local Government Board were wrong in their plea that Mr. Cullen's resignation (sent to the Local Government Board and to the board of guardians but not accepted by the latter) rendered his position vacant, but that *per contra* the appointment of him as a "locum-tenent" signified that the dispensership at Castleknock was vacant. The latest stage of this weary case, and one which perhaps gives it some additional importance, is as follows On Feb. 27th the weekly meeting of the North Dublin Rural District Council was held when the Lord Mayor of Dublin, Mr. Harrington, M.P., after a speech in which he arraigned the action of the Local Government Board, proposed a motion that Mr. Cullen was a fit and proper person to fill the position of medical officer to the Castleknock and Blanchardstown district. That was, of course, directly opposed to the decision of the Irish Local Government Board, which had notified in a formal letter published in the papers that Mr. Cullen was inadmissible as a dispensary officer for that district, although he was eligible for any other Poor-law appointment. In accordance with the direction of the Board that a new election must be held, the guardians later that day received applications from five candidates for the post legally vacant. The applicants included Mr. Cullen, and he was re-elected by a majority of 35 to 3. It seems impossible to say positively what may be the outcome of this unfortunate conflict between the Local Government Board for Ireland and the guardians of the North Dublin Union, but the matter must be settled very soon. The guardians complain that the Board were discourteous in omitting to lay before them the evidence received at the inquiry and the reasons which led the Board to require the resignation of the guardians' medical officer in whom they always had, and still continue to have, confidence. The Local Government Board cannot, however, be expected to alter the decision at which they arrived so many months ago and which they have since upheld by expensive legal proceedings.

Death of Mr. Bellew Kelly of Drogheda.

Mr. Bellew Kelly, J.P., whose death took place on Feb. 28th after a short illness, was one of the best known, most popular, and most highly esteemed of provincial practitioners in Ireland. He was a Fellow of the Royal College of Surgeons in Ireland for more than a quarter of a century and was looked upon as a trustworthy consultant in the county of Louth for many years. He formerly filled the office of high sheriff there, was a vice-president of the Irish Medical Association, and held many local appointments which are now rendered vacant by his death.

Presentation to Mr. Frederic W. Kidd, M.D. R.U.I.

A committee representing the staff, students, and nurses of the Coombe Lying-in Hospital who wished to mark the occasion of the termination of Dr. Frederic W. Kidd's period of office as master of the institution by some token of their esteem, waited on him at his residence on March 1st and presented him with a valuable watch.

The Health of Belfast.

At a meeting of the Statistical and Social Inquiry Society of Ireland, held in Dublin on Feb. 22nd, a paper was read by Councillor H. O'Neill, M.D. R.U.I., on the Progress of Sanitary science in Belfast. In returning the thanks of the society to Dr. O'Neill for his lecture the Registrar-General for Ireland (Mr. Matheson) gave some statistics in order to put before the society exactly the state of things in Belfast with regard to its death-rate and the public health. From the returns issued in his department it appeared that during last year there were registered as having occurred in Belfast 42 deaths from measles, 14 from scarlet fever, 2 from typhus fever, 145 from whooping-cough, 54 from diphtheria, 8 from simple continued and ill-defined fever, 261 from enteric fever, 241 from diarrhœa and dysentery, 1115 from phthisis, 1784 from diseases of the respiratory system, and 163 from various other maladies. In this list he directed special attention to three features, the first of which was the large number of deaths from enteric fever, which were 261 in 1900, 263 in 1899, 640 in 1898, 354 in 1897, 136 in 1896, 188 in 1895. 145 in 1894, 122 in 1893, 108 in 1892, and 151 in 1891. In other words, for the past 10 years the average deaths from enteric fever in Belfast had been 236, and these deaths were not in one locality but were scattered all over the city. The mortality from this disease was very serious in Dublin, but it was worse in Belfast for while the average was 154 for the 10 years in Dublin it was 236 in Belfast. The circumstances of the two cities were very different. In Dublin they had an old city with a legacy of very old houses and the soil polluted with the accumulation of filth for years and years. Belfast, on the contrary, was a comparatively new city and a good deal of it had been built within a period during which the requirements of sanitary science were pretty well known. Being curious to see in what class of houses enteric fever was found in Belfast the Registrar-General extracted from the records of his department the addresses of the persons who died from enteric fever in 1900, and he found that about a third of the cases occurred in houses which did not appear in the Belfast Directory of 1892 and which presumably had been built since that time. He would like to know more about the sanitary regulations introduced in the year 1892, what their nature was with regard to the sewerage of new houses since that date, and also what steps had been taken with regard to the sewerage generally in Belfast, seeing that this terrible disease existed all over the city, and that a large number of the cases must have been in houses comparatively recently built. The second serious feature in the mortality returns of Belfast was that the number of deaths from diphtheria amounted in 1900 to 54, and that 17 of these deaths, according to his returns, occurred in No. 12 district which in 1891 had a population of 23,000. He found that eight of these 17 occurred in houses which did not appear in the Belfast Directory of 1892 and which, he presumed, were houses erected since that date. The disease being connected with imperfect sewerage, how did it come about that so large a number of deaths were found in this particular quarter? The third feature in the death returns in Belfast was the 1115 deaths from that terrible disease phthisis. So far as his department was concerned the Registrar-General said that they would give the Corporation of Belfast every assistance to make their city a model one as regarded its public health. It need

hardly be added that this sweeping condemnation of the sanitary condition of Belfast, coming from an official like the Registrar-General of Ireland, has aroused a great deal of interest in that city and demands the utmost attention. At the meeting of the City Council held on March 1st the chairman of the Public Health Committee (Alderman J. Graham, M.D. R.U.I.), referred to the statement recently made by the Irish Registrar-General. He said that the department over which that gentleman presided was the most stupid of all the departments in Dublin Castle. When they estimated the population of Belfast in 1891 they under-estimated it by about 21,000, while they over-estimated the population of Dublin by 9000, and that made a serious difference when the respective death-rates were taken into account. Before making statements as he had done the Registrar-General should have made adequate inquiries in reference to the causes of enteric fever in Belfast. In his opinion there were other causes of enteric fever in Belfast than in the insanitary condition of the houses. There was the water-supply. With a pure water-supply Belfast would be one of the healthiest cities in the kingdom. Dr. Graham said he would like to tell the Registrar-General that in 1895 their death-rate in Belfast was 24·3 per 1000, and they had now reduced that to 21, while in Dublin the death-rate in 1895 was 30 per 1000, and at the present time it was 30·3. It did seem extraordinary that a gentleman in the position of the Registrar-General should make such charges against a city of which he prides himself that he was not an inhabitant, and he thought he had been very ill-advised in his attack on the health of Belfast. An animated discussion followed in the council after these remarks of the chairman of the Public Health Committee, some of the councillors defending the water commissioners, while others, as for instance Dr. J. D. Williamson, blamed the erection of houses on filthy and polluted "made" soil as the great cause of the prevalence of enteric fever in Belfast. Even at the present time, despite all the rules existing in reference to these so-called "dumped" grounds, it is stated that houses continue to be erected in situations where the soil is certainly not the virgin one.

The Royal University of Ireland.

At a meeting of the council of the Royal University Graduates' Association held on March 1st in reference to the proposed Commission of inquiry into the working of the Royal University of Ireland resolutions were passed requesting that such a Commission, if appointed, should be constituted after the manner of the Gresham or London University Commission which, in addition to its president, Earl Cowper, was composed of five eminent scientific, five literary, and two legal members. It was also urged that no person who had committed himself to any particular policy on the Irish University question or who is connected with any of the institutions likely to be dealt with by the inquiry should be appointed on the Commission. Further, the council condemned "the false and mischievous statements made by persons in official position in connexion with the Royal University of Ireland tending to lower the character of its degrees, which, notwithstanding admitted defects in the constitution of the examining board, are recognised by those who understand university affairs as not surpassed by those of any other university in the kingdom."

Belfast Maternity Hospital.

At the annual meeting of the supporters of this charity, held on Feb. 26th, the report which was presented showed that during the past year 282 patients had been treated in the wards with only one death and that in the extern department 204 poor patients had been attended in their own homes. The total receipts during the year had been £788 11*s.* 2*d.*, while the expenditure had been £713 9*s.* 3*d.* The capital account had been drawn upon to some extent.

The Responsibility of Medical Men for Certificates delivered by themselves.

DOCUMENTS written by medical men under the name of medical certificates which they hand over to their patients who are desirous of giving evidence as to the state of their health before courts of law or other authorities are very often given without due consideration. Too often the patient looks upon a certificate as something which the medical man cannot refuse, and the latter in his turn acts wrongly in acceding to the patient's wishes in the same spirit. The result is lamentable weakening of the trust reposed in these certificates, which have the name of *certificats de complaisance*, and nearly all the courts now insist upon a sworn expert examining them with a view to checking the statements therein contained. A certain number of trials which have lately taken place show that these certificates have their risks for the medical man whose responsibility is at stake. Some time ago a pharmaceutical chemist was convicted of assault by cutting and wounding a lady named R——. She produced a certificate signed by Dr. D——, and at the same time brought two witnesses of the assault. Later the pharmacist was able to furnish proofs that the whole case had been got up to injure him and that the two witnesses had been bribed by the woman. All three were sentenced to three years' imprisonment. The pharmacist next brought an action against Dr. D—— for having furnished a false certificate. As a matter of fact, all that he had done was to write down the patient's statement without taking the trouble to verify it. He was sentenced to pay a fine of 500 francs, the court, while censuring his imprudence, throwing no doubts upon his good faith. The judgment declared that although from the point of view of treatment or for prescribing the medical man may put faith in the statements of the patient, yet he must not certify as an actual fact and as verified by a personal examination the existence of an injury which he has not himself verified, and Dr. D——'s imprudence was all the more culpable inasmuch as he knew that his certificates were intended to furnish grounds for an action at law against another. A somewhat similar case has just been before the courts at Caen. A person named D——, to avoid payment of a debt, succeeded in making out that his creditor was a lunatic and in getting her placed in an asylum on the strength of a certificate furnished by Dr. C—— alleging that she was out of her mind. After eight days she was set at liberty since the asylum physicians could find no sign of madness about her. She accordingly claimed damages from M. D—— and from Dr. C——, the latter of whom was sentenced to pay 2000 francs damages. The court, in giving judgment, was of opinion that Dr. C—— had acted imprudently, carelessly, and in a profoundly mistaken manner; that although he had acted in good faith he was wrong in placing blind confidence in the obviously interested statements of D—— and his wife who represented the alleged lunatic as dangerous both to themselves and to the community; that he had not ascertained or determined upon any obvious manifestation of acute mania such as was attributed, without, however, any details being given, in his certificate referring to the alleged lunatic; that this was the more inexcusable inasmuch as he himself had known the alleged lunatic for a long time and was well aware that she had never shown the least sign of mental instability; and that he had formed his opinion simply upon the statements of the D——s, both husband and wife, without submitting the alleged lunatic to any examination or observation whatever and without any attempt to get at either the truth or the importance of the facts laid before him. Again, only last year a medical man was prosecuted for having given a certificate to one of his patients setting forth that the said patient was unfit for military service, and that without ever having been to see the patient who was in perfect health. As a rule medical men give these certificates owing to having too great regard for the feelings of their patients whom they do not wish to offend, but the various trials mentioned above must show them that by so doing they render themselves liable for much responsibility.

Hæmorrhage during Appendicitis.

At the meeting of the Academy of Medicine held on Feb. 19th M. Lucas-Championnière said that in his opinion the hæmatemeses which had been observed during an attack of appendicitis were comparable to the "black vomit" which had been noticed after certain abdominal operations. While allowing their extreme gravity he thought that they were sometimes curable, and mentioned that he had occasionally been able to put an end to them by washing out the stomach with an alkaline solution. He considered that the observations of M. Dieulafoy[1] pointed to the increasing frequency

[1] THE LANCET, March 2nd, 1901, p. 669.

of appendicitis, and that, too, under a graver form than previously. If in former times appendicitis had been as frequent as now the fact would surely have been noted by observers. These remarks applied equally to the appendicitis of pregnant women, of which disease M. Pinard had reported three cases as occurring in one month, although he himself had seen but one case in the 10 years during which he had practised obstetrics. Appendicitis, if not absolutely new, is at all events a different complaint from the typhlitis and perityphlitis of former days. As regards this point M. Lucas-Championnière stated that he was one of the first to advocate free and early opening of abscesses of the iliac fossa. From 1882 to 1898 he had operated on 34 such cases, while in 1899 and 1900—i.e., in two years—he had operated upon 19. If this proportion had existed during the former period the number would have been 152. Nowadays appendices are removed as a preventive measure and therefore iliac abscesses should become more rare. The increased frequency of appendicitis is due to the increase of the causes of intestinal infection, and he had been struck by the fact that appendicular affections were most common in meat-eating countries, such as the United States and England. The unmerited discredit into which purgatives have fallen also tends to cause intestinal infections. In the old days children were well purged at every change of season—a wise precaution which has fallen into desuetude. Purgation is the best way to fight against intestinal infection and this treatment could not be too strongly recommended provided that at the same time a strict dietary was enforced. In this way a large number of cases of appendicitis might be prevented from occurring. The discussion was continued on Feb. 26th, when M. Guyon gave an account of three cases of hæmatemesis due to urinary infection. He argued that these cases were a confirmation of the infectious origin of appendicular hæmatemesis. M. Dieulafoy said that he thought it likely that such conditions as were wont to be called intestinal occlusion, colic, volvulus, and abscess in the iliac fossa were entirely due to an unrecognised appendicitis, for laparotomy was then by no means common. M. Dieulafoy did not dare, as did M. Lucas-Championnière, to prescribe washing out the stomach in the cases of appendicular "black vomit." He considered that rest was necessary so that clots might form. He quite agreed with M. Lucas-Championnière that once a diagnosis was made operation was necessary. M. Lucas-Championnière said that despite everything appendicitis was increasing in frequency. All his cures had been obtained after washing out the stomach, for the removal of clots and the alkaline fluid diminished acidity and gave rest to the organ. M. Pinard hardly thought that appendicitis was really increasing, but in obstetric practice the peritonitis of pregnancy and that due to rupture of adhesions were now referred to their true cause—namely, appendicitis. M. Kelsch declared that he regarded appendicitis as a malady at first generalised, but which ended by giving rise to local manifestations. On this theory it was possible to compare the appendicitis of dysentery, of cholera, of influenza, and of cerebro-spinal meningitis, and to recognise that as these affections were either endemic or epidemic, so appendicitis might appear at certain epochs, might increase in frequency, or might disappear.

March 6th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Bacteriology of Acute Rheumatic Arthritis.

IT is very probable that in many cases of acute rheumatic arthritis the tonsil has been the channel of infection. In a paper read before the Verein für Innere Medicin and published in the *Deutsche Medicinische Wochenschrift* Dr. Meyer, assistant in the clinic of Professor A. von Leyden, announces that he has discovered a microbe which he suggests is of importance in connexion with the etiology of rheumatic arthritis. This organism was present in the tonsils of five patients suffering from rheumatic arthritis and when injected into rabbits caused symptoms very similar to that disease. It is described as a rather small diplococcus which usually forms chains. It is easily stained by anilin colours, but only to a slight extent by Gram's method. It does not grow well on any of the usual culture media, except on blood-agar. In growing it forms single soft droplets, which under the microscope show yellowish granular colonies with a somewhat darker centre. The cultures after a short time lose their virulence. When eight cubic centimetres of the culture were injected under the skin of rabbits much infiltration generally ensued, leading to necrosis of the skin but never to suppuration. After from six to 10 days one of the joints usually became swollen in consequence of serous or sero-purulent exudation containing no bacteria. The exudation disappeared after a week, but as a rule other joints were subsequently involved. The temperature of the animals rose to 40° or 41° C.; they, however, in most cases did not die. At the necropsy inflammation of the serous membranes was found as in the acute rheumatic arthritis of the human subject. Pericarditis was found in eight instances, peritonitis in three, and pleurisy in one. The results of the bacteriological examination of the fluid were negative. In seven instances endocarditis was present, partly in the warty and partly in the ulcerative form. In these seven cases the above-described organisms were met with twice in pure culture, and subcutaneous injections in rabbits again gave rise to articular exudation. In five instances the cultures remained sterile. Dr. Meyer concluded from his researches that these organisms producing specific effects on animals were characteristic of acute rheumatic arthritis because they were present only in the tonsils of patients suffering from that disease, and were never found in tonsillitis associated with other diseases, such as scarlet fever, septicæmia, influenza, &c. It is, however, doubtful whether the microbe is really the cause of the disease.

The late Professor von Pettenkofer.

The funeral of Professor von Pettenkofer, whose death has been already announced in THE LANCET,[1] took place on Feb. 12th. There was an enormous attendance, including every class of the population of Munich, where the deceased was one of the most popular citizens. In the cemetery appropriate addresses were delivered by the mayor of Munich on behalf of the city and by Professor von Ziemssen on behalf of the university. At the necropsy chronic meningitis of the dura mater and sclerosis of the cerebral arteries were found; there was also a chronic inflammation of the right knee-joint which had caused deformity and much pain and had contributed a good deal to the mental depression from which the deceased had suffered.

Vomiting induced by Chloroform Inhalation.

Vomiting is one of the most undesirable complications of chloroform anæsthesia. According to a recent article by Dr. Lewin this symptom is caused by direct irritation of the stomach by the chloroform and not, as in the case of some other toxic substances, by an irritation of the brain. In the first stage of the anæsthesia, when the lungs are filled with chloroform vapour, the patient executes the movements of swallowing and the chloroform is brought into contact with the mucous membrane of the stomach. It then depends on the degree of irritability of the gastric nerves whether vomiting takes place or not. The vomiting which occurs after the end of the anæsthesia and often continues for several hours is caused by chloroform which has passed into the circulation and is eliminated through the gastric glands. There has not hitherto been any certain means of guarding against this complication. The principal precaution is, of course, for the patient not to take food for a certain time previous to the induction of the anæsthesia so that the stomach may be empty; but everybody knows that vomiting cannot be absolutely prevented in this way, for even in surgical clinics and hospitals where the patients are under strict observation vomiting is very frequent during, or after, anæsthesia. Dr. Lewin's views of the causation of vomiting during chloroform anæsthesia have led him to suggest that the sensibility of the nerves of the stomach may be reduced by means of a local anæsthetic and that its mucous membrane may be covered with a substance which will to some extent protect it from the chloroform. He recommends the administration of cocaine in a small dose (one decigramme) dissolved in sufficient water to flow over the whole of the mucous membrane. For the mechanical protection of the stomach against the action of chloroform he recommends mucilaginous substances which from their adhesive power tend to remain a somewhat long time in the stomach. The most suitable substances are one part of gum arabic dissolved in two parts of water, carrageen moss, and tragacanth. It is desirable that the patients should

[1] THE LANCET, Feb. 16th (p. 490) and 23rd (p. 589), 1901.

take a dose of this from three to four hours previous to, and another dose immediately before, the operation.

March 4th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Imperial Medical Society.

THE Imperial Medical Society, which was founded by the medical officers of the allied armies in 1855, celebrated its forty-sixth anniversary on Feb. 15th. It is on this day that the election of officers takes place. The officers for the session 1901–1902 are as follows: President, Dr. Mordtmann, representative of the German Empire on the International Sanitary Council; vice-presidents, Dr. Stepochief (the chief physician of the Russian Hospital) and Dr. Noulis. The outgoing secretaries were re-elected. The following honorary members were elected: (1) Dr. Caramitza, professor of pathology in the medical school of Athens, who celebrated the twenty-fifth anniversary of his professorship in that university in February; (2) Dr. Walter Wyman, supervising surgeon-general of the United States Marine Hospital Service; and (3) Professor Heubner of Berlin. At the conclusion of the elections the members of the society dined together and the new President proposed the health of the Sultan. It is greatly to be desired that the statements made in the President's speech should come to the knowledge of the Sultan, as something might then be done to place the society in a more satisfactory position. The Turkish Government seems to forget that the Imperial Medical Society is the oldest scientific association in Turkey and is entitled to the credit of initiating all the sanitary improvements which have been made in the country.

Public Health in Constantinople.

The prevailing disease here since the beginning of the winter has been influenza, which, however, has been of a mild character. Many of those who are attacked think it unnecessary to have medical attendance and prefer to treat themselves with domestic remedies. A lady who suffered from influenza and was following this system met with a sad accident a few weeks ago. While applying to her chest an alcoholic solution of camphor she thoughtlessly went too near a stove, the alcohol caught fire, and she was so severely burned that she died in two days. In addition to the influenza there have also been some cases of measles and diphtheria.

Plague.

A girl, aged five months, who had been taken on board at Alexandria died on the steamer *Apollo* a few hours before the arrival of the vessel at Rhodes on Feb. 13th. The medical officer of the sanitary service at Rhodes having found enlarged glands in the child's right groin and armpit, the passengers and crew and the inhabitants of Rhodes who had been in communication with them were at once placed under medical observation and the vessel was sent to the lazaretto at Clazomenes for disinfection and for the making of a microscopical examination of the child's enlarged glands.

The International Sanitary Council.

Some progress has been made towards the adjustment of the difficulties which have arisen in connexion with the appointment of the inspector-adjoint of the International Sanitary Council. As I have already mentioned,[1] the Turkish delegates on the council, according to the international stipulations, must not exceed eight in number and two of these must be medical men professing the Christian religion. After the death of Dr. Vitalis, the late inspector-adjoint, the Turkish Government appointed two delegates, one who had been a custom-house official and one who was a medical man, so that the number of Turkish delegates was raised to nine, and the foreign Governments protested. The Turkish Government have found a way out of the difficulty by promoting Lutfi Bey, one of the Turkish delegates and a medical man, to the rank of pasha and general, and he will accordingly leave the sanitary service and take his place among the medical officers of the army. The appointment of the new inspector-adjoint still has to be made. He must be a medical man professing the Christian religion, must have been engaged in the sanitary service, and must have travelled in Turkey so as to possess an acquaintance with the sanitary condition of the country.

March 1st.

[1] THE LANCET, Dec. 22nd, 1900, p. 1846.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Infection of Contagious Diseases in Clothing.

THE health officer of the Port of New York, Dr. A. H. Doty, in a paper read at the late meeting of the American Public Health Association, took the ground that infectious diseases were rarely communicated by the clothing of persons. In a recent letter he replied to criticisms of his opinion as follows:—"What I presented was not a theoretical conclusion but a plain statement of facts which have come under my observation during a continued experience of 20 years with infectious diseases, both in connexion with this department and the New York City Board of Health. I am well aware that what I have said is antagonistic to the views held by many physicians, nevertheless it is the result of careful, practical observation, and such observation must receive the most careful consideration in making rules and regulations for the protection of the public health. Some of the most careful observers, both in this country and abroad, are in accord with the views which I have presented. As a matter of fact, these views are apparently endorsed by the medical profession, both in private practice and in matters relating to public health, inasmuch as physicians daily visit infectious diseases and go from them directly to other patients without disinfection or change of clothing. Moreover, health departments throughout the country permit their inspectors and diagnosticians to visit infectious disease in the same manner. For instance, in families where scarlet fever exists the adult members, who are actively employed outside, are allowed to continue their business without interruption. Of course, they are usually admonished not to enter the apartment of the sick when at home. In a large percentage of cases the patient roams about the house or apartment at will. Therefore, if the clothing worn by well persons was a medium of infection to the extent which is commonly believed, we would certainly and surely have indisputable evidence of it, which we do not. If such were the case physicians and health department officials would be continually aiding and abetting the propagation of disease in the most serious and pronounced way, inasmuch as they go directly from one patient to another, sometimes within the interval of only a few moments. I have distinctly stated in my paper that infectious diseases may in some cases be transmitted through the medium of the clothing of well persons. This statement gives no licence to ignore reasonable precautions which may be deemed necessary to prevent the transmission of infection in this manner. I believe this answers the point raised by the committee in regard to small-pox quarantine. As a matter of fact, the small-pox patient should in no case remain with the family; and either the patient or the remainder of the family should be removed from the immediate premises. Therefore, no excuse would exist for persons, aside from the nurse and physician, visiting or being in contact with the patient, which would be done at a personal risk. My object has been to show that infectious diseases are not commonly transmitted in the clothing usually worn by well persons, and we must not give this undue consideration in making rules and regulations for the protection of the public health. While this does not release us from every reasonable effort to prevent danger from this source it teaches us that we must also look elsewhere for the origin of outbreak of infectious disease. It is an easy means of satisfying ourselves and the public to assume that outbreaks of small-pox, scarlet fever, &c., have their origin in infected clothing worn by well persons, whereas in many of these instances the appearance of the disease is unquestionably due to mild ambulant or convalescent cases in our midst unrecognised. If we are satisfied that the clothing of well persons is in some way responsible for the outbreak, then we are apt to make no further investigation, which I believe to be decidedly wrong. Bacteriological research goes far towards confirming what I have already said regarding this matter and we know that pathogenic organs are exceedingly short-lived in the presence of air and sunlight. Experience in the New York City Board of Health for 15 years before assuming this office, both in the

capacity of diagnostician and the Chief of the Bureau of Infectious Diseases, has given me an opportunity for the study of this subject which comes to very few. We cannot preach one thing and act another. If it is true that the clothing of well persons acts as a medium of infection, then both physicians and health departments are committing a serious error in the manner in which they visit their cases. On the other hand, if the clothes actually worn by the well persons only in rare instances act as a medium of infection, as I believe, then the attitude of physicians and health departments in regard to their inspection of these cases is proper."

Defining the Term "Practice of Medicine."

The New York County Medical Society is endeavouring to secure the passage of an Act by the Legislature which shall so define the term "practice of medicine" as to include and render easy the punishment of all exponents of false and fraudulent systems of medical treatment. It provides that "Any person shall be regarded as practising medicine within the meaning of this Act, who shall prescribe, recommend, direct, or advise for the use of any other person, any remedy or agent whatsoever, whether with or without the use of any medicine, drug, or instrument, or other appliance for the treatment, relief, or cure of any wound, fracture, or bodily injury, infirmity, mental or physical, or other defect or disease." A few exceptions follow such as the administration of domestic remedies by one member of a family to another and the treatment of their men by army and navy officers. It is alleged in opposition that the Bill, as it stands, would prevent one from advising a friend to invest in a box of cough drops and would render it illegal for the manfacturers of proprietary medicines to advertise in the usual way, for an optician or truss-maker to serve customers not provided with a physician's prescription; or for a shoemaker to take into account a patron's corns in providing him with boots. The pharmacists are opposing the Bill on the ground that it would prevent the advertising of medicines, the printing of directions on bottles by the manufacturers of the medicines, and the recommendation of any such medicines by druggists.

Exemption of Hospitals from Liability.

Suits against hospitals for damages are becoming so frequent that the institutions are seeking legislative relief. A Bill at present before the New York Legislature provides that no hospital incorporated under the law of the State, sustained in whole or in part by charitable contributions or endowments, shall be liable for the neglect, carelessness, want of skill, or for the malicious acts of its officers, agents, or employés in the management of or in the care or treatment of any of the patients or inmates of such hospital. It shall not be lawful for any such hospital to make or to enter into any agreement whereby liability shall be incurred for such neglect, want of skill, or malicious acts, and any such agreement shall be void. Nothing in the Bill shall be so construed as to impair any remedy under existing laws which any persons may have against any officer, agent, or employé for any wrongful act or omission in the course of his official conduct or employment.

Stimulating Effect of Lofty Altitudes with Accompanying Exercise.

It is reported that at the suggestion of the director of the biological laboratory of the University of New Mexico, the late Dr. Maltby undertook a study of the blood of persons in the plateau region, and this work, interrupted by his death, has been prosecuted with vigour by Professor Weinziri, who has collected a large amount of data. It is found that the blood corpuscles are greatly increased in number when a person from a low altitude reaches a higher one, but this effect, with the powerful stimulus involved, is only transitory, and the curve representing the blood corpuscles soon grows less, and finally returns to the level of the starting point. Observations have shown that while persons who have long resided in New Mexico have no more blood corpuscles than those residing in lower regions, these same persons may renew or repeat the original effect of altitude by a short residence at the seashore or elsewhere. What amounts to the same thing is that one residing at an altitude of 4000 or 5000 feet may secure all the powerful stimulating effect of the altitude on the blood by periodical visits to the altitude of Santa Fé or Magdalena, 3000 feet higher. In these cases the effect is greatly increased by out-door life and exercise because there is an intimate relation between the activity of the lungs and the blood stimulation. At the same time, it was found that rabbits kept in confinement would show the same increase on being carried from Albuquerque to Camp Whitcomb.

Feb. 18th.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the second examination of the board at the quarterly meeting of the examiners in the subjects indicated:—

Anatomy and Physiology.—John Aylen, St. George's Hospital; Ernest Charles Edward Barnes and Charles Harold Berry, University College, London; Tom Bates and John Arthur Bell, St. Bartholomew's Hospital; John Foster Beale, B.A. Cantab., Cambridge University and London Hospital; Hugh Wood Bethell, Cambridge University and Guy's Hospital; Bartram Raleigh Bickford, Charing Cross Hospital; Gerald Arthur Bradshaw, St. Mary's Hospital; Frederick William Broderick, Mason University College, Birmingham; James Bromley and Claude Marriott Lovell Cowper, Guy's Hospital; Stephen Estridge Crawford, St. Bartholomew's Hospital; Harry William Beresford Danaher, London Hospital; Norman Edwin Dunkerton, King's College, London; William James Edgar, St. Thomas's Hospital; Armin Gascoigne Vavasour Elder, St. George's Hospital; William Henry Elwood, Queen's College, Belfast; Charles Ashley Flintoff, Charing Cross Hospital; Christian Ernest Paul Groth, London Hospital and Cambridge University; Sydney Herbert Gibson, B.A. Cantab., and Thomas Barker Amyand Haggar, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Vahan Hagopos James Giragosian, Horace Bryden Hill, and Richard Holtby, St. Bartholomew's Hospital; James Clark Hall, St. George's Hospital; Cuthbert Murray Halsall, University College, Liverpool; Thomas Brooke Hickley, Westminster Hospital; Nelson Wood Hill, London Hospital; Eardley Lancelot Holland, King's College, London; Mark Oliver Hunter, B.A. Cantab., Cambridge University and St. George's Hospital; Henry Johnson, Guy's Hospital; Graham Charles Lawson, Cambridge University and St. Thomas's Hospital; William Kingdon Legassick, University College, London; Thomas Clarkson Maxwell, King's College, London; Reginald Henry Miller, St. Mary's Hospital Robert Vernon Giraud Monckton, St. Bartholomew's Hospital; Herbert Edward Morris, Guy's Hospital and Cooke's School of Anatomy and Physiology; Basil Newman Murphy, University College, Liverpool; Krishna Moreshwar Pardhy, L.M. and S. Bombay, Grant Medical College, Bombay; Christopher Parker, Westminster Hospital; Arthur Robert Phelps, Cambridge University and St. Thomas's Hospital; William Frederic Pierce, Owens College, Manchester; Carl Henry Reinhold, Guy's Hospital; Vyvyan Kendall Sadler, University College, London; Arthur Philip Salt, St. Bartholomew's Hospital; Eric Slack, B.A. Cantab., Cambridge University and Middlesex Hospital; Douglas Montague Brooking Snell, St. Thomas's Hospital and Durham University; William Arthur Tatchell and Henry Blanchard Walters, London Hospital; Frederick Herbert Wallace and Hugh Watts, Guy's Hospital; Vernon Northwood Whitamore, Charing Cross Hospital; and Ralph Kuper White, St. Mary's Hospital.

Anatomy only.—Andreas Nell, L.M. and S. Ceylon, Colombo Medical College, Ceylon, and University College, London, and Clifford Greville Simms, Middlesex Hospital and Cooke's School of Anatomy and Physiology.

Physiology only.—James John Anning, Yorkshire College, Leeds, and Rowland Wilbraham Hill, Owens College, Manchester.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Preliminary Science Examination for the Licence in Dental Surgery at the quarterly meeting of the examiners:—

John Joseph Armitage, North Polytechnic Institute, Holloway Francis William Bartle, City of London College; Tom Treherne Barton, Charing Cross Hospital; Horace Stanley Chandler and Horace Croot, Guy's Hospital; Alfred Braithwaite Charlick, School of Science, Technology, and Art, Liverpool; William Alexander Clements, Municipal Technical School, Manchester; R. Wilfrid Cross, Holt School of Science, Birkenhead; Gerald Lang Dymott, Birkbeck Literary and Scientific Institute; Archibald Roland Durant, Edward Farrant, Archibald Louis George, and Albert Goodey, Guy's Hospital; Arthur Barber Hawkes and Alfred John Higson, Charing Cross Hospital; William Hopton and Alfred Henry Mace, Owens College, Manchester; Harold Whightman Jones, Guy's Hospital; Bannar Harry Martin and Rupert Josiah Messent, Municipal Technical School, Brighton; Percy Norman Owen, Mason University College, Birmingham; Charles Lucey Palmer, Reading College, Charles Cook Pooley, Higher Grade Board School, Norwich; Frank Ernest Probyn and Percy Hartley Rodgers, Charing Cross Hospital; Leonard Urban Ransford Norman Bowden Soper, William Stuart Stevens, and Thomas Vernon, Guy's Hospital; Ernest Le Masurier Spurgin, Municipal Technical School, Brighton; Attilio Regolo Setacci, Polytechnic Institute, Regent-street, and Joseph Hindle Westmorland, Owens College, Manchester.

The following gentlemen having passed the necessary examinations have been admitted by the two Royal Colleges Diplomates in Public Health:—

Thomas Gibson, M.D., C.M. Edin., Edinburgh University and King's College, London; Thomas Halliwell, L.R.C.P. Lond., M.R.C.S. Eng.,

Guy's Hospital; Hugh Campbell Highet, M.D., C.M. Glasg., Glasgow University; Thomas Battersby Jobson, M.D. Dublin, Trinity College, Dublin, and St. Bartholomew's Hospital; Peter Narrainasawmi Lakshmanan, L.R.C.P. Lond., M.R.C.S. Eng., M.B., C.M., Madras, Madras University and King's College, London; Charles Gordon Moffit, L.R.C.P. Lond., M.R.C.S. Eng., University College, London; Claude Rundle, M.B.Lond., L.R.C.P. Lond., M.R.C.S.Eng., St. Mary's Hospital and King's College, London; and Arthur Herbert Spicer, M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S. Eng., Guy's Hospital.

UNIVERSITY OF CAMBRIDGE.—At the congregation held on Feb. 28th the following degrees were conferred:—

M.B.—C. J. Coleman, Trinity.
M.B. and B.C.—W. H. W. Attlee, St. John's; and F. E. Brunner, Caius.

THE LATE MR. J. P. BEVAN.—Mr. John Paul Bevan died suddenly from an apoplectic seizure at his residence, North-place, Cheltenham, on Feb. 25th, in his fifty-third year. Mr. Bevan was the son of a Nonconformist minister and was born at Oakham, Rutlandshire. He received his medical education at Guy's Hospital and became qualified as M.R.C.S. Eng in 1873 and L.R.C.P. Lond. in 1874. Mr. Bevan then commenced practice in Cheltenham and in 1874 he was appointed medical officer for the No. 1 district of the Cheltenham Union—a post he held till the time of his death. He was also for several years public vaccinator and surgeon to the Cheltenham Dispensary.

LITERARY INTELLIGENCE. — M. G. Steinheil medical and scientific publisher, 2, rue Casimir-Delavigne, Paris, asks us to state that original subscribers (i.e., since the year 1878) to Professor Tarnier's "Traité d'Accouchements" may now obtain from their booksellers the newly-published fourth and last volume. Subscribers who paid their subscriptions to the publisher direct are requested to inform him how the fourth volume is to be sent to them. If forwarded by post it will be registered, unless otherwise specially directed, the cost of postage and registration being 1 franc 60 centimes, to be paid in advance. The contents of the four volumes are as follows: 1. Grossesse et Accouchement Physiologiques; 952 pages, 285 illustrations. 2. Pathologie de la Grossesse; 586 pages, 66 illustrations. 3. Dystocie Maternelle; 771 pages, 168 illustrations. 4 Dystocie Fœtale; Opérations; 734 pages, 250 illustrations.

ROYAL FREE HOSPITAL. — The Marquis of Northampton presided on Feb. 27th at the seventy-third annual court of the governors of the Royal Free Hospital, Gray's Inn-road. The annual report stated that the total number of patients who had been treated during the year was 36,560, the majority of these patients coming from the neighbourhood in which the hospital is situated, one of the most crowded and poorest in the metropolis. The chairman, in moving the adoption of the report, referred to the loss which the charity in common with many others had sustained in the death of its Royal patron, Queen Victoria. With reference to the report, he expressed himself as being struck with the consecutive progress made by the hospital. The building had been greatly improved and every effort had been made to bring the hospital up to the standard of modern requirements. The total reliable income being only one-third of the necessary expenditure it behoved all present and their friends to do their utmost to lessen the harassing care of the committee who had to carry on the work. No doubt much had been given during the past year to the military funds, but surely it was clear, said the chairman, that true charity lay in giving extra when circumstances made it urgent; no charity was worth the name that did not call for self-sacrifice. Mr. Charles Burt, chairman of the weekly board, seconded the motion, and stated that the hospital began the year with a debt of £1300 and the financial position caused the board much anxiety. The hospital was most economically administered, although the work in each department was done thoroughly and efficiently. Mr. Burt announced that in May next the governors would make a new departure by appointing two qualified medical women as resident medical officers to attend women and children patients. A further resolution was passed that a petition be sent to the King humbly praying His Majesty to continue the patronage which was accorded to the hospital by Queen Victoria throughout the 64 years of her glorious reign. Among other speakers were the Earl of Stamford, Captain Jessel, M.P., Mrs. E. Garrett Anderson, M.D., Dr. S. West, and Mr. James Berry. At the close of the proceedings the governors visited the wards and the new rooms provided for the nursing staff.

COOKERY EXHIBITION.—The twelfth Universal Cookery and Food Exhibition will be held this year at the Prince's Skating Club, Knightsbridge, from June 11th to the 15th.

MEASLES NEAR BARNSTAPLE.—At the meeting of the Barnstaple Board of Guardians, held on March 1st, Mr. G. L. Thornton, the district medical officer, stated that a severe epidemic of measles had broken out in the country district, and he was allowed an assistant for a fortnight.

BRISTOL ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—Earl Roberts, K.G., V.C., at the instigation of the Duchess of Beaufort (president of the bazaar committee), has promised to open, on May 1st, at the Colston Hall, the bazaar in aid of the funds of the Bristol Royal Hospital for Children and Women.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—A meeting of the Fellows will be held on Tuesday, March 19th, at 1 o'clock, to elect two members of the Council. One vacancy was caused by the death of Mr. A. H. Jacob and the other by Sir William Thomson being unable to make the requisite declaration within one month of his election. The candidates for the vacancies are Sir William Thomson and Mr. Robert H. Woods, both surgeons to the Richmond Hospital, Dublin.

CHARITY AND THE DRAMA.—Dr. Lionel A. Weatherly gave an interesting lecture on March 1st at the meeting of the Bath Literary and Philosophical Association on "Reminiscences of 30 Years of Amateur Acting." Major Simpson presided and referred to the fact that Dr. Weatherly had during his 30 years of amateur acting been instrumental in raising no less than £10 000 for various charities. Dr. Weatherly, who is well known in connexion with the amateur week in aid of the Royal United Hospital, Bath, was at the close of the lecture awarded a hearty vote of thanks.

CHARITABLE DONATIONS. — At the annual meeting of the friends of the Liverpool Country Hospital for Chronic Diseases of Children on March 4th a letter was read from a writer, whose name was not disclosed, who said: "I shall be very pleased to give a donation of £5000 to your building fund provided you can get three other donations of £5000 each, thus making up your building fund to £20,000, and that a further sum of £10,000, in any sums, be raised as a maintenance fund and invested in the names of your trustees, the interest alone to be expended." A cheque was received for £1000 from Mr. Holbrook Gaskell, and one for £500 from Mr. A. L. Jones.

PRESENTATIONS TO MEDICAL MEN. — At a numerously attended meeting on March 2nd of ambulance representatives, held at the fire station, Council House, Handsworth, Mr. James Richmond, M.B. Oxon., M.R.C.S. Eng., D.P.H., was the recipient of a "surprise pendant" gaselier as a mark of appreciation for his services to the Handsworth centre of the St. John Ambulance Association.—Mr. Harry Hutchinson, L.R.C.P. Irel., L.F.P.S. Glasg., L.S.A. Lond., of East Ham, has been presented by a few personal friends and patients in the locality with a gold-mounted dressing-bag, a set of aseptic surgical instruments, and a large silver tray.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—The Earl of Hardwicke presided at the annual meeting of governors and subscribers of this charity, which was held at the hospital in the Marylebone-road on Feb. 25th. Among those present were the following: Mr. F. G. Cavendish Bentinck, Rev. Henry W. Casserly, Mr. F. Herbert Davies, Captain Norcliffe Gilpin, Mr. H. A. Harben, Mr. F. W. Hunt, Mr. Richard Martin, Major W. McMahon, Mr. H. J. Royds, and Dr. Arthur F. Stabb.—Lord Hardwicke referred to the great loss which the nation had sustained by the death of Queen Victoria, and stated that Her late Majesty had been patron of the charity from the year 1850 until her death, and had been a generous subscriber to its funds. The committee had sent a letter of condolence to His Majesty the King. The report stated that 1183 in-patients and 971 out-patients had been delivered during the year, including 75 wives of soldiers, sailors, and reservists who were fighting in South

Africa (55 as in-patients and 20 as out-patients). Her late Majesty Queen Victoria had, only a few days before her death, been graciously pleased to express her gratification at the special facilities that had been arranged for receiving the soldiers' wives, and Her Majesty Queen Alexandra had also expressed her great pleasure that these arrangements had been made. The expenditure for the year had been £871 in excess of the income, and the chairman made an urgent appeal for additional support to enable the committee to meet the increased expenditure caused by the larger hospital and the increase in the number of patients and by the rise in prices of many articles of hospital consumption.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Proposed Exemption of Hospitals from Local Rates.

MR. LAWSON WALTON has introduced in the House of Commons a Bill providing for the exemption of hospitals from local rates. The place obtained for the order for its second reading is not one which offers much hope of the measure being discussed.

Hours of Labour in Shops.

The question of the hours of labour in shops is to be inquired into by a Select Committee of the House of Lords on which the Prime Minister, the Bishop of Winchester, Lord Avebury, and other peers will serve.

HOUSE OF LORDS.

THURSDAY, FEB. 28TH.

Ambulance Wagons and Hospital Tents.

Lord RIBBLESDALE called the attention of the House to the suggestions made by the South African Hospitals Commission with regard to ambulance wagons and hospital tents and asked the Government whether any steps had been taken or were contemplated for giving effect to them.—Lord RAGLAN (Under Secretary of State for War) replied that changes were in contemplation in the pattern both of the ambulance wagons and of the hospital tents, and experiments were now being made, but it was extremely difficult to find the ideal tent or the ideal wagon; and at present it was undesirable to put a stop to inquiry and experiment. The War Office was anxious to benefit by the experience of officers who had been in South Africa, some of whom were not yet home; but up to the present the following steps had been taken: In July last a new pattern ambulance was built to the specification of the Royal Army Medical Corps and was sent down to Aldershot for experiment and report. The wagon was 1cwt. lighter than the old pattern and it carried more men The old pattern carried 12 men seated or four seated and two on stretchers. The new pattern carried 14 seated or six seated and four on stretchers The War Office had obtained as much information as possible about the ambulances in use in foreign armies, especially about the Austrian ambulance, of which many favourable reports had been received. This type had been sent to Aldershot for report and would then be sent to Woolwich, where the officials would confer with officers of the Royal Army Medical Corps and of the transport department who had recently returned from South Africa. The question of tents was much complicated by the question of climate. The tortoise-tents were at first reported on very favourably from South Africa, but recent reports were not so good. It was not the ideal tent in bad weather; and another, more satisfactory, seemed to have been found. Trials of many kinds of tents were made last summer and autumn. Although there was unusual pressure at the War Office no time would be lost in remedying any defects which could be dealt with immediately.

HOUSE OF COMMONS.

THURSDAY, FEB. 28TH.

Woodstock Hospital still Being Used.

Mr. ARTHUR STANLEY asked whether Woodstock Hospital, Cape Town, was still being used for enteric fever patients, and whether, in view of the smells which were acknowledged to exist at Woodstock, any steps had been taken to find another and more suitable site in the neighbourhood of Cape Town.—Lord STANLEY replied that the hospital was still being used for enteric fever patients. Many improvements had recently been made in the hospital and the senior medical officer in charge now described everything as satisfactory. The only change contemplated was the removal of the drainage outfall.

The Small-pox Epidemic in Glasgow.

Mr. THOMAS BAYLEY asked the Lord Advocate if he would institute an inquiry into the outbreak of small-pox in Glasgow in a manner similar to that in which the Local Government Board had granted inquiries on the occasions of recent outbreaks in England; and if he would extend such inquiry into the sanitary conditions of the city and its water-supply.—The LORD ADVOCATE: I am informed by the Local Government Board for Scotland that there does not seem to them to be any reason at present for instituting an inquiry into the sanitary condition of Glasgow and its water-supply. The reference to the practice of the English Local Government Board is, I am informed by that Board, rather misleading. That Board usually send one of their medical inspectors to a district where small-pox is epidemic, in order that he may assist the local authorities with his advice and experience, but the Board have not on any recent occasion held an inquiry into an outbreak of small-pox.

FRIDAY, MARCH 1ST.

Lead and Arsenic Poisoning.

Mr. COGHILL asked the Home Secretary whether his attention had been called to the evidence given before the Arsenical Poisoning Commission as to the similarity of the symptoms of poisoning from arsenicised beer and from plumbism, and that Professor Oliver and Professor Thorpe had reported that beer was largely taken in the Staffordshire potteries as an antidote to plumbism; and whether many of the reported cases of plumbism in the last four months of 1900 were cases of arsenical poisoning.—Mr. RITCHIE: Having made inquiries into this matter I find that during the last four months of 1900 three cases reported as cases of plumbism were considered by the medical inspector of factories and workshops to be really cases of arsenical poisoning and were excluded from the returns of lead poisoning. The cases are always carefully scrutinised for mistakes in reporting, and there is no reason to think that there were any other such cases not detected.—Mr. COGHILL: Was complaint made of the beer supplied by the local brewers during these months?—Mr. RITCHIE: I have received no such complaint.

The London Water Question.

Mr. WALTER LONG, in reply to Dr. MACNAMARA, said that he had no power to require the water companies to pay the cost of the public inquiry into the proposed new regulations. He might add, he said, that if he possessed the power he should not consider that it ought to be exercised in this case.

MONDAY, MARCH 4TH.

No. 8 General Hospital.

Mr. BURDETT-COUTTS asked the Secretary of State for War whether he was aware that No. 8 General Hospital, one of the two largest hospitals at Bloemfontein, had remained on the same site for over 10 months, the ground being thoroughly infected with enteric poison in consequence of the number of enteric fever cases treated there during and since the epidemic of last year; whether, in view of the increased rate of mortality from enteric fever in South Africa, immediate inquiry would be made as to why this hospital camp, in accordance with recognised principles of sanitation, should not have been long since moved to an entirely new site; and whether he could give the number of enteric fever cases admitted to this hospital and the number of enteric fever deaths in it during each of the six months ending Jan. 31st.—Mr. BRODRICK: I am informed that this hospital has remained on the same site for 10 months, but there appears to be no reason for anxiety, as the site has been reported to be perfect and the sanitary reports up to Jan. 18th state that the general sanitary conditions were good. The figures of this hospital are as follows:—viz., August—admissions 220, deaths three; September—admissions 154, deaths none; October—admissions 26, deaths one; November—admissions 49, deaths five; December—admissions 61, deaths three; January to 25th—admissions 93, deaths 12. The admissions in January are mostly of transfers from out-stations. The type of enteric fever is reported in January as severe, many of the cases being practically hopeless from the first. If any doubt is found to exist as to the sanitary condition I will undertake that the situation shall be changed.

Civil Practitioners in South Africa.

Mr. BURDETT-COUTTS asked the Secretary of State for War if he would state with regard to the last 50 civilian surgeons and physicians engaged by the Royal Army Medical Staff Corps for employment in South Africa the length of time for which each had been legally qualified before being sent out.—Mr. BRODRICK replied: 10 were qualified in 1901, 10 in 1900, and nine in 1899; the remaining 21 have been qualified for varying periods going back as far as 1876.

TUESDAY, MARCH 5TH.

Pneumonia on Board the Britannia.

Captain PRETYMAN (Civil Lord of the Admiralty) said, in reply to questions on this subject, that it was true that two cadets and one of the instructors of the *Britannia* had recently died from complications following upon pneumonia and on Sunday last there were 16 cadets ill, two seriously. The cause of the large amount of pulmonary disease was the prevailing epidemic of influenza of a severe type. The hospital was by no means full. The cadets had been granted three weeks' leave and the ship would be thoroughly purified and disinfected while the cadets were away.

Lead-poisoning among House-painters.

Mr. COGHILL asked the Home Secretary whether his attention had been called to the death of Richard Edwards, a house painter of 33, Pinnox-street, Tunstall, caused, as a coroner's jury found, by lead-poisoning; and whether he proposed to introduce any legislation for the protection of house-painters from lead-poisoning.—Mr. RITCHIE: I have inquired into the case and find that it does not come within any Act which I have to administer, and I do not see my way to proposing any such legislation as is suggested.

Plague at the Cape.

Sir WALTER FOSTER asked the Secretary of State for the Colonies whether he could state the number of cases of plague that had occurred at Cape Town, according to his latest advices, distinguishing the number of Europeans and the number of natives attacked; whether at the time of the outbreak of the malady the authorities at Cape Town had an adequate supply of Haffkinine (prophylactic vaccine) and of Yersin's curative serum for dealing with an outbreak, and whether a supply of these materials had since been sent out; and whether he would lay upon the table any reports received from Dr. Edington or Professor Simpson on the relation of the disease in rats to that in human beings.—Mr. CHAMBERLAIN: My information is not complete, but, as stated in the telegraphic bulletins which have been supplied by the Cape Government and published, there was a total of 20 cases for the week ending Feb. 16th and 29 cases remaining under treatment at that date. On Feb. 23rd there were 21 cases remaining under treatment. So far as I am aware there has been one European case. As to the second part of the question I have no information; the matter is one for the responsible Government of the Cape Colony. As to the third part, I have not seen these reports which I understand are being prepared for the information of the Cape Government, and I am not aware that they have been published by that Government.

ROYAL COMMISSION ON ARSENICAL POISONING.

Evidence of Dr. James Niven.

THE Royal Commission on Arsenical Poisoning held another meeting on Friday, March 1st, in one of the rooms of the Westminster Palace Hotel, and examined Dr. James Niven, medical officer of health of the city of Manchester. All the members of the Commission were present and Lord KELVIN occupied the chair.

Dr. NIVEN, in reply to the CHAIRMAN, said that the evidence which he possessed as to the amount of recent exceptional sickness in Manchester attributable to poisoning by arsenic was derived from the answers to a circular sent by him to medical practitioners on Nov. 27th and from statements which had been made in reference to the public institutions of the city. Answers were received from 186 out of a total of 358 medical practitioners, from which it was inferred that not less than 1000 cases had occurred in the experience of the gentlemen who answered the circular. The number estimated by Dr. E. S. Reynolds to have been admitted to the Crumpsall Infirmary was 500. All these would be cases of persons who were at the time of their illness dwelling in the old Township of Manchester, having an estimated population in the year 1900 of 144,139. The number admitted to the Withington Workhouse Infirmary could not have been less than 200, most of whom would be Manchester residents. It was, in his opinion, safe to infer that not less than 2000 cases had been seen by medical men within the last six months. About one-half of the medical men of Manchester did not send any reply to his circular. Their failure to reply he attributed simply to pressure of work, not to any desire to keep cases secret. Many medical men had such an immense amount of work that they were run off their feet and quite tired out in the evening, and he presumed that they simply did not feel equal to sitting down and replying accurately to a document of this description There were a very large number of causes which gave rise to peripheral neuritis. The reason why one looked upon all or the great majority of these recent cases as having been due to arsenical poisoning was partly the short period within which the illness had begun. It had not been a gradually dawning illness, but an illness marked by a somewhat definite onset, and these cases had all been associated with the drinking of beer or stout. Taking these things into consideration, one regarded at all events the recent cases of peripheral neuritis as mostly due to the influence of arsenical poisoning. There had been no other cause at work that one was aware of. Indeed, the only other cause one could think of was alcoholic poisoning. There could be no doubt that many of the medical practitioners in the early stages of the outbreak looked upon these cases as cases of alcoholic poisoning, between which and cases of arsenical poisoning it was difficult to make a precise and clear distinction. A table had been prepared showing for the city of Manchester the number of deaths from peripheral neuritis, from other neuritis, from chronic alcoholism, from cirrhosis of the liver, from other diseases of the liver, and from gastritis, in each week of the past five years. This table showed that deaths from peripheral neuritis and from other neuritis had been increasing in number since 1896 and that the number of deaths from chronic alcoholism and from cirrhosis of the liver had fluctuated from one year to another but that from each of these causes of death a great increase had occurred in the year 1900. This increase was most marked in the last half of the year and in the case of peripheral neuritis was confined to it. In the last 26 weeks of the year 37 deaths were registered from this cause as against 11 in the first 26 weeks of the year. From chronic alcoholism 66 deaths were registered in the second half of the year as against 43 in the first half of the year. From cirrhosis of the liver 75 deaths were registered in the second half of the year as against 51 in the first half. That arsenical poisoning had in each instance had to do with this increase was certain; that it was responsible for the whole of it could only be determined by a study of the revenue returns, which would show whether there had been a great increase of drinking during 1899 and 1900. If this could be shown, arsenical poisoning would not be excluded, but it would not be possible to regard it as the sole cause of the increase. From an analysis he had prepared it seemed that women died from peripheral neuritis more than men and at an earlier stage. A given quantity of arsenic would have a greater effect on a woman than on a man, and no doubt the drink of women was more exclusively beer and stout than in the case of men. It was a common thing for women to meet in the afternoon and gossip over a pot of beer got from a neighbouring public-house. The exceptional sickness and death had been confined to adults—a circumstance which went far to exclude sweets, jams, bread, &c., as sources of arsenical poisoning. A number of samples of cheap sweets and jams had been examined for arsenic but had been found free from it in appreciable amount. Six samples of cheap wine had been examined but no arsenic had been found in them.

By Dr. WHITELEGGE: Have you any case of peripheral neuritis in which there was no consumption of beer at all?—I believe there is one case. The patient was 47 years of age. The early symptoms were nausea, vomiting in the morning, and pain in the hands and feet and upon pressure of the calf. The observations of the physician at the hospital were that the patient had slight difficulty in walking, dilatation of the right side of the heart, pain in the soles of the feet, excessive sweating of the hands and feet, eruptions, thickening of the skin, and peeling. This patient denied having taken beer. I know the district and street from which this patient comes, and I think it would not be well to attach an undue degree of importance to the denial. In this case the patient recovered.

Dr. NIVEN, in further examination by the CHAIRMAN, said that so far as the observations made at the union infirmaries and other public institutions went, and so far as the testimony of Manchester practitioners went, the symptoms of arsenical poisoning had been confined to persons drinking beer and stout almost exclusively of the cheaper qualities. The exceptions to this statement were trivial. A selection was made of 85 cases, presenting well-marked features, with two or three exceptions, and brief histories of the illness were obtained through Dr. Reynolds at Crumpsall, and Dr. J. S. Orchard at the Withington Workhouse. In 63 of these it was possible to trace the beers habitually used by the patients to the breweries producing them. In every instance the brewery in question had used Bostock's sugars. It had been ascertained that these sugars had been used by 12 out of the 23 Manchester breweries. In the majority of the cases beer from the same brewery, but obtained at public-houses other than those frequented by the patient, was found to contain arsenic in appreciable amount. He could not speak of his own knowledge, but he believed that a large number of cases of peripheral neuritis occurred among the employés of the breweries in Manchester. The highest amount of arsenic ascertained was about one-half grain per gallon, but all the samples examined quantitatively were taken after the sanitary committee had issued a warning to publicans by means of the daily press. 81 samples of beer had been examined by him or under his direction, and of these 27 had been found to contain arsenic. These were all taken after the announcement of the discovery of arsenical poisoning by beer. From analyses which had been published and from those which had been made for him it was evident that the large amounts of arsenic found in samples of beer taken about Nov. 20th and onwards could only have been derived from arsenical glucoses and inverts. The quantities of beer found to produce symptoms of arsenical poisoning and the period within which those symptoms were produced pointed in the same direction. The arsenious acid was introduced into the glucose in the process of conversion from starch by the use of contaminated sulphuric acid and into the invert sugar in the same way. The amounts of arsenious acid found in malt could not have produced the results which had been observed. He was strongly of opinion that there should be no arsenic present in any brewing materials and that there was no justification for its presence. In the case of malt the arsenic got in during the process of kiln-drying. It was, of course, difficult to obtain a fuel absolutely free from arsenic, but the fumes might be kept away from the grain. In any case if arsenic were deposited it ought to be removed just as it ought to be removed from hops. Dr. Niven then offered to the Commission the following suggestions, viz.:—

1. That manufacturers of foods and drinks in the preparation of which chemicals are employed should be required by law to have printed in clear characters on any order sent to the vendor of such chemicals the words "to be used in the manufacture of foods or drinks," as the case might be. The words "foods or drinks" to include materials intended for immediate consumption as well as materials (such as brewers' sugars) to be used in the preparation of foods or drinks.

2. That persons supplying chemicals to be used in the manufacture of foods or drinks should be required by law to affix conspicuously and securely to each consignment of chemicals to be used for such purpose a clear printed statement in adequate size of type that the materials supplied are "for the manufacture of foods or drinks." Such a statement should also be required to be printed on invoices of such consignments.

3. It is suggested that without such a statement conspicuously affixed to any consignment of chemicals it shall be illegal, under a penalty, to use chemicals from such consignment for the manufacture of foods or drinks.

4. As regards malt and hops and other materials used in brewing, it shall be illegal for such materials to be contaminated with arsenic.

5. It is desirable that the Food and Drugs Act should be amended so as to ensure that, in case of any deleterious contamination occurring in beer or stout, it may be possible to trace the source of the contamination, and so to ensure the destruction of the deleterious article.

By Sir WILLIAM HART DYKE, M.P.: The intention with regard to the last suggestion was that the authorities should be able to pass from the retailer to the brewer and thus to get hold of the stock of contaminated beer and have it destroyed.

By Professor THORPE: In his opinion the epidemic was now practically at an end. There was nothing to have prevented him from applying to the city analyst of Manchester for assistance in connexion with this inquiry, but he thought that in matters requiring special skill and very exact and careful investigation involving a great consumption of time it might be an advantage in large towns to have some consulting body such as an institute of public health to refer to for assistance. He was of opinion that the whole of the mischief was attributable to arsenic. The arsenic found was amply sufficient to account for all the mischief.

By Sir WILLIAM CHURCH: He had been told by brewers that even before the alarm about arsenic many people stopped drinking beer because it made them sick, and no doubt the catarrhal symptoms put off the suspicion of arsenic.

By Dr. WHITELEGGE: In the administration of the Sale of Food and Drugs Acts the analyst as a rule would look for adulterations, not for poison, and before this epidemic witness would not have expected an analyst to examine beer for arsenic. If he could prove by samples the presence of arsenic in beer at a brewery he could seize the stock and get it condemned by a justice of the peace, but he did not think he had the same power with respect to a chemical manufactory, because it would be difficult to show that the products were used for food. He was inclined to think that there was no longer any seriously contaminated beer in Manchester.

The Commission then adjourned until Wednesday, March 6th.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ADAMS, A. J. B., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Children's Homes, Barnes, Richmond, Surrey.

ADAMS, JOSEPH DIXON, M.D. St. And., M.R.C.S., L.S.A., has been reappointed Medical Officer of Health by the Yeovil Rural District Council.

ANGOVE, E. S., L.R.C.P. Edin., M.R.C.S., has been appointed District Medical Officer to Flaxton Out-relief Union, vice E. W. Mason.

BEVAN, A., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

BIRKBECK, L. H. C., B.A., M.B., B.Ch. Oxon., has been re-appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.

BLACK, Major JOHN GREER, M.D., M.Ch.R.U.I., R.A.M.C., has been appointed to the charge of the Station Hospital at Devonport.

BLEASE, ARTHUR TORKINGTON, L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Royal Infirmary, Manchester.

BOND, THOMAS FRANCIS, M.D. Lond., M.R.C.S., F.R.S. Edin., has been re-appointed Medical Officer of Health by the Chepstow Rural District Council.

BURFIELD, T., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

COATES, C. J. A., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory Acts for the Stokenchurch District of Bucks.

COPE, R., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon to the York County Hospital.

CLARKE, H. H. R., L.R.C.P., M.R.C.S., has been re-appointed House Physician to St. Thomas's Hospital.

CUNNINGHAM, J. F., L.R.C.P., M.R.C.S., has been appointed Senior Ophthalmic House Surgeon to St. Thomas's Hospital.

DAVIES, BOWEN W. L., M.R.C.S., L.R.C.P., has been appointed Honorary Medical Officer to the Denbighshire Infirmary, vice T. Lloyd Roberts, resigned.

DAWSON, W. R., M.D., F.R.C.P.I., has been appointed Examiner in Mental Disease in the University of Dublin.

DEWDNEY, E. L. D., L.S.A. Lond., has been appointed District Medical Officer, Williton Union, vice J. Hardie, resigned.

DOUDNEY, G. H., M.B. Durh., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Wainfleet District of Lincolnshire.

DOUGLAS, CLAUDE, F.R.C.S., L.R.C.P., has been appointed Surgeon to the Leicester Infirmary, vice C. H. Marriott, resigned.

DUDGEON, L. S., L.R.C.P., M.R.C.S., has been re-appointed Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

EDMOND, W. R., M.B., C.M. Edin., L.R.C.P. Edin., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Totnes District of Devon.

EDWARD, A. A., M.D. Edin., has been appointed Certifying Surgeon under the Factory Acts for the Borough of Rawtenstall.

EDWARDS, T. H., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St Thomas's Hospital.

EGLINTON, GEORGE WALTER, L.R.C.P., L.M. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health for the Wells (Somerset) Rural District Council, vice Joshua Charles Smyth, L.R.C.P. Lond., M.R.C.S., resigned.

GORDON, T. E., M.D. Durh., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Towyn District of Merioneth.

GRAY, E. B., M.D. Oxon., President of the Society of Medical Phonographers, has been appointed Consulting Physician to the Oxford County Asylum at Littlemore, vice the late Sir Henry Acland.

GRIMWADE, A. S., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

HARRIS, H. S., L.R.C.P., M.R.C.S., has been appointed Junior Ophthalmic House Surgeon to St. Thomas's Hospital.

HAY, M. S., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the North Devon Infirmary, Barnstaple, vice F. Penny, resigned.

HEDLEY, E. W., M.A., M.B., B.C. Cantab., has been appointed Senior Obstetric House Physician to St. Thomas's Hospital.

HUNT, S., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

LOCK, J. L., B.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed Assistant House Physician to St. Thomas's Hospital.

MARTIN, A. E., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

MARQUIS, H. A., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer, North Bierley Union, vice W. A. Shillito, resigned.

MENNELL, Z., L.R.C.P., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

MENCE, W. C. L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

NITCH, C. A. R., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

PALMER, W. M., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Linton District of Cambridgeshire.

PATERSON, T. W. S. M.A., M.B., B.C., has been re-appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.

PATERSON, T. W. S., M.A., M.B., B.C., has been re-appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

PEARSON, A., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer, Newark Union, vice A. J. Rowbotham, resigned.

RISDON, GEORGE OWEN, L.R.C.P. Lond., L.S.A., M.R.C.S., has been re-appointed Medical Officer for the No. 2 District of the Wells (Somerset) Union.

ROCHE, ANTONY, M.R.C.P. Irel., has been appointed Examiner in Medical Jurisprudence and Sanitary Science in the Royal University of Ireland.

SADLER, F. J., M.B., B.Ch. Oxon., D.P.H., has been appointed Certifying Surgeon under the Factory Acts for the Barnsley District of the West Riding of York.

SAWYER, J. E. H., B.A., M.B., B.Ch. Oxon., has been appointed Assistant House Physician to St. Thomas's Hospital.

SELOUS, C. F., L.R.C.P., M.R.C.S., has been re-appointed House Physician to St. Thomas's Hospital.

SKERRETT, F. B., B.Sc. Lond., L.R.C.P., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

STANNUS, H. S., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

TAYLOR, T. S., M.A., M.B., B.C. Cantab., has been appointed House Surgeon to St. Thomas's Hospital.

THORNE, ATWOOD, M.B. Lond., has been appointed Assistant Surgeon to the London Throat Hospital, Great Portland-street.

WALKER, J. H. S. M.B., C.M. Edin., D.P.H. Aberd., has joined the staff of the Clinical Research Association, Limited, as a Director of the Laboratories.

WATERHOUSE, RUPERT, M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Resident Medical Officer to the Royal United Hospital, Bath.

WILLS, B. S., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

WOODS, W. H. O., M.B., B.C. Cantab., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BEDFORD COUNTY HOSPITAL.—House Physician for six months. Salary £25 for that period, with board, lodging, and washing.

BOROUGH HOSPITAL, BIRKENHEAD.—Senior and also Junior Resident House Surgeon. Salary £100 and £80 respectively per annum, with board and washing.

BOROUGH HOSPITAL, Bootle, Liverpool.—Senior Resident. Salary £100 per annum, with board, &c.

CARDIFF INFIRMARY.—Honorary Assistant Surgeon.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant for three months on payment of £8 8s.

CITY FEVER HOSPITAL, Lodge-road, Birmingham.—Assistant Medical Officer. Salary £120 per annum, with board, residence, &c.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park. Physician to the out-patients. Also Second House Physician for six months. Salary at the rate of £30 per annum, with board and residence.

CITY POORHOUSE AND HOSPITAL, Parliamentary-road, Glasgow.—Junior Assistant Medical Officer. Salary £90 per annum, with board, apartments, &c.

CORPORATION OF LONDON.—Medical Officer of Health, 35 to 50 years of age. Salary £1000 per annum.

CUMBERLAND INFIRMARY, Carlisle.—Resident Medical Officer as House Physician during the first six months, and House Surgeon during the ensuing six months. Salary at the rate of £80 and £100 per annum respectively, with board, lodging, and washing.

DERBYSHIRE ROYAL INFIRMARY, Derby.—Assistant House Surgeon for six months. Salary £30, with board, residence, and washing.

GENERAL HOSPITAL, Birmingham.—Surgical Officer. Salary £100 per annum, with residence, board, and washing.

GLASGOW EYE INFIRMARY.—Assistant House Surgeon. Salary £50, with apartments and board.

GREAT NORTHERN CENTRAL HOSPITAL.—Junior House Surgeon for six months. Salary at the rate of £30 per annum, with board, lodging, and washing.

GUEST HOSPITAL, Dudley.—Senior Resident Medical Officer. Salary £100 per annum, increasing to £120, with board, residence, attendance, and washing.

HOSPITAL FOR WOMEN, Liverpool.—House Surgeon for six months. Honorarium £25, with residence.

HULME DISPENSARY, Stretford-road, Manchester.—House Surgeon. Salary £150 per annum, with apartments, attendance, coal, and gas.

KING'S COLLEGE HOSPITAL, Lincoln's Inn-fields, W.C.—Clinical Pathologist.

LIVERPOOL STANLEY HOSPITAL.—Senior House Surgeon. Salary £80 per annum, with board, residence, and washing.

LIVERPOOL WORKHOUSE, Brownlow-hill.—Assistant Medical Officer. Salary £80 per annum, with rations and apartments, and an additional £20 for examining applicants for out-door relief.

LONDON HOSPITAL, Whitechapel, E.—Surgical Registrar. Salary £100 per annum.

LUNATIC ASYLUM, Isle of Man.—Assistant Medical Officer. Salary £100 per annum, with apartments, washing, and board.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £70 per annum, with board and residence.

MANCHESTER CHILDREN'S HOSPITAL.—Junior Resident Medical Officer, unmarried, for six months, eligible for election as Senior for another six months. Salary at rate of £80 a year as Junior and £100 a year as Senior, with board and lodging.

MANCHESTER PORT SANITARY AUTHORITY.—Port Medical Officer. Salary £350 per annum.

METROPOLITAN ASYLUMS BOARD.—Assistant Medical Officers, unmarried, not over thirty-five years of age, at the Fever and Small-pox Hospitals. Salary £160 per annum, rising to £200, with board, lodging, attendance, and washing.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician, House Surgeon, Assistant House Physician, and Assistant House Surgeon for six months. Salary at the rate of—House Physician and House Surgeon, £40 a year; Assistant House Physician and Assistant House Surgeon, £20 a year.

NEW HOSPITAL FOR WOMEN.—Female Anæsthetist.

NORFOLK AND NORWICH HOSPITAL, Norwich.—House Surgeon, unmarried, not over thirty years of age. Salary £80 per annum, with board, lodging, and washing.

NORTHAMPTON GENERAL INFIRMARY.—Physician, not under twenty-five years of age.

NORTHERN INFIRMARY, Inverness.—House Surgeon. Salary £100, with board, &c.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Dental Surgeon.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon. Salary £140 per annum, all found except board.

PARISH COUNCIL OF WESTRAY, Orkney.—Medical Officer and Public Vaccinator. Salary £90 per annum.

PATHOLOGICAL LABORATORY (UNIVERSITY OF CAMBRIDGE) — John Lucas Walker Studentship.—Annual value £200, tenable under certain conditions for three years.

PRESTON ROYAL INFIRMARY.—Junior and Assistant House Surgeons. Salaries £80 and £60 per annum respectively, with board, lodging, and washing, &c.

ROTHERHAM HOSPITAL.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ROYAL ALBERT HOSPITAL, Devonport.—Resident Medical Officer, unmarried. Salary £110 per annum, with board and lodging.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Resident Medical Officer, for six months. Salary at the rate of £120 per annum, with furnished apartments, board and washing.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Ventnor.—Assistant Resident Medical Officer, unmarried. Salary £100 per annum, with board and lodging in the hospital.

ROYAL SEA BATHING HOSPITAL, Margate.—Assistant Resident Surgeon. Salary £60 per annum, with board and residence.

RURAL DISTRICTS COUNCILS OF EPSOM AND DORKING AND THE URBAN DISTRICT COUNCILS OF CARSHALTON, DORKING, EPSOM, AND LEATHERHEAD.—Medical Officer of Health.

ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, London, E.C.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

SUFFOLK GENERAL HOSPITAL.—House Surgeon. Salary £100 a year, with board, lodging, and washing.

THE CHIEF INSPECTOR OF FACTORIES gives notice of vacancies as Certifying Surgeons under the Factory Acts at Coningsby in the County of Lincoln and at Woking in the County of Surrey.

THROAT HOSPITAL, Golden-square, W.—Non-resident House Surgeon. Salary £100 per annum, with lunch.

TORBAY HOSPITAL, Torbay.—House Surgeon. Salary £100 per annum and £5 for the nurses' lectures. Board, lodging, washing, &c.

TOWER HAMLETS DISPENSARY, Stepney, E.—Resident Medical Officer. Salary £120 per annum, furnished rooms, coals, gas, and attendance.

TUNBRIDGE WELLS GENERAL HOSPITAL.—Resident House Surgeon, unmarried. Salary £100 per annum, with board, furnished apartments, &c.

VICTORIA HOSPITAL FOR CONSUMPTION, Craigleith, Edinburgh.—Resident Physician, for six months. Residence, board, and a small honorarium to cover conveyance.

WALTHAMSTOW URBAN DISTRICT COUNCIL.—Resident Medical Officer for the new Isolation Hospital at Chingford. Salary £120 per annum, with board and lodging.

WARNEFORD HOSPITAL, Leamington.—House Surgeon. Salary £100 per annum, with board, washing, and apartments.

WARNEFORD ASYLUM, Oxford.—Assistant Medical Officer, unmarried. Salary £100 a year, with board, lodging, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician and also House Surgeon for six months. Board and lodging provided.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—Lecturer on Biology.

WOOLWICH INFIRMARY, Plumstead.—Assistant Medical Officer, unmarried, not over 30. Salary £150 per annum, with apartments, rations, and washing.

Births, Marriages, and Deaths.

BIRTHS.

MURISON.—On March 5th, at 6, Pier-road, Erith, Kent, the wife of W. R. Murison, L.R.C.P. & S. Edin., of a son.

WAINEWRIGHT.—On Feb. 27th, 1901, at 49, Wickham-road, Beckenham, Kent, the wife of Robert S. Wainewright, M.D. Lond., of a son.

WHITE.—On March 5th, at Westlands, Upper Richmond-road, Putney, S.W., the wife of E. F. White, F.R.C.S., of a daughter.

WROUGHTON.—On March 3rd, at Wetheral, near Carlisle, the wife of William Haultain Wroughton, M.R.C.S., L.R.C.P. Lond., of a daughter.

MARRIAGES.

MURSELL—THOMSON.—On Feb. 18th, at St. Stephen's Church, Gloucester-road, S.W., Henry Temple Mursell, M.B., F.R.C.S., elder son of the Rev. Arthur Mursell, to Helen Foggo, second daughter of the late James Thomson, of Edinburgh.

VINCENT—PEPPIATTE.—On the 4th inst., at St. Marylebone Church, by the Rev. E. W. Raby, M.A., Ralph Vincent, M.B., B.S., M.R.C.P., of 1, Harley-street, W., eldest son of Ralph Vincent, of Leytonstone, to Mary, only daughter of Pelet Peppiatte, of Ware.

DEATHS.

BERRY.—On Tuesday, March 5th, at Margate, Sydney H. Berry, M.B. Lond., F.R.C.S. Eng., of 90, Kellett-road, Brixton, S.W., aged 27. (Recently of Charing Cross Hospital).

BEVAN.—Feb. 25th, at Cheltenham (suddenly) John Paul Bevan, M.R.C.S., L.R.C.P., son of the late Rev. John Bevan, aged 52 years.

CHEYNE.—At 75, Harley-street, W., on Feb. 22nd, Julia Millicent, daughter of W. Watson Cheyne, aged 9 months.

GODFREY.—On Feb. 27th, Graham Philip Godfrey, L.R.C.P., L.R.C.S. Edin., aged 40, son of the late Thomas Godfrey of Mansfield.

GRIFFITH.—On March 3rd, at Grace's-road, Camberwell, John William Griffith, M.D., aged 82.

WHITE.—On Feb. 27th, Samuel Shapland White, M.D., of Queen's-road, Tunbridge Wells.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

INTERFERENCE.

To the Editors of THE LANCET.

SIRS,—I hold the appointment of medical officer to a small convalescent home for soldiers. The home is managed by a committee with a lady secretary. In the course of my treatment of one of the men the lady secretary (on her own responsibility apart from the committee) wrote requesting me to hold a consultation over the case. I refused, on the ground that I was the fit person to judge when this should be necessary and that the suggestion should come from me. The matter was referred to the committee, when the chairman, an eminent military surgeon, disagreed with me. I should be very much obliged if you would tell me what you think of the matter and if, in your opinion, I exceeded my right.

I am, Sirs, yours faithfully,

March 5th, 1901. M.R.C.S.

*** The medical man in charge of a patient is the proper person to decide if a consultation is necessary. If the patient himself or any of his relations or intimate friends suggest a consultation the medical man should be ready to fall in with the idea. No one else should interfere in the matter.—ED. L.

THE FIDGETS.

To the Editors of THE LANCET.

SIRS,—In reply to H. M. W. D. in THE LANCET of Feb. 16th, page 524, warmth, if persevered in, will cure the "fidgets." Warm cycling knickers should be worn and also warm woollen stockings with putties or well-fitting gaiters. Knitted woollen knee-caps must be worn at night. Give half a grain of opium daily two hours before usual time of attack of "fidgets." Massage to abdomen and lower extremities might do good in this case.

I am, Sirs, yours faithfully,

Feb. 25th, 1901. I. M. S.

PUBLIC DINNERS WITHOUT WINE.

To the Editors of THE LANCET.

SIRS,—I have read with much interest your leading article "Legislation against National Intemperance" in THE LANCET of Feb. 9th, p. 410. Might I suggest that the officials of the London medical schools would be helping the cause of temperance amongst medical students if they ceased to force alcohol down their throats (as it were) at their annual dinners? I have for the last eight or 10 years regularly protested against the guinea tickets *including wine* which are issued for the annual dinner of my old alma mater (University College), and to which first year's medical students are so cordially invited, but up till now no change has been made. Equally good dinners can be arranged without compulsory wine. The British Medical Association always issues dinner tickets *without wine*, but medical students are not invited to these functions.

I am, Sirs, yours faithfully,

Harley-street, Feb. 14th, 1901. BERNARD ROTH.

MEDICAL FEES AT CORONERS' INQUESTS.

To the Editors of THE LANCET.

SIRS,—Can you or any of our medical coroners give me information on the following questions? Has a coroner elected by the county council power to summon a medical witness and to disallow his fee when he has given medical testimony? Secondly, if a coroner has no such power can I sue him or the county council? What is my remedy, the coroner having disallowed my fee?

I am, Sirs, yours faithfully,

March 5th, 1901. FELLOW.

*** It is not unknown for a coroner in certain circumstances to refuse fees to a medical witness. His power to do so in a particular case can only be ascertained by legal action. The proceedings should be against the coroner and should only be undertaken with legal advice.

"NEW EDITIONS OF SCIENTIFIC WORKS."

To the Editors of THE LANCET.

SIRS,—In the last number of THE LANCET that reached me (issue of Dec. 1st, 1900) I notice an editorial comment on the letter of a correspondent on New Editions of Scientific Works. Your correspondent's proposal for the printing of appendices (containing *all the corrections, additions,* and *new illustrations* in revised editions of standard works) is not so difficult as you seem to think. The printing of a good appendix would of course necessitate the setting up of the type separately, but the publishers could readily adjust the price of the appendix to the cost of production, and so far from the venture being a financial loss I am convinced it would add considerably to the profits of the book. Surely a book that can be issued at, say, 15s., could have an appendix published at a profit if sold for two or three shillings, or more, according to the expense o

production. Under existing circumstances many medical men of limited means cannot afford to continue buying each new edition of standard works, many of which appear every two or three years, whereas they would gladly pay a reasonable sum for a good appendix. The latter would, of course, be of no use to purchasers who did not possess an original copy of the book, and the sale of the corrections separately could not therefore interfere in any way with that of the work itself. As it is, many of us prefer to buy an entirely new work on a given subject to purchasing the new edition of an old work at a high price. Trusting that some publisher with a quick perception of his own interests as well as of the needs of his *clientèle* will see these remarks and put the venture to the test,

I am, Sirs, yours faithfully,

VICTOR E. H. LINDESAY, Capt. I.M.S.

China Expeditionary Force, IV Goorkhas,
Shanghai, Jan. 20th, 1901.

THE DUTIES OF SURGERY ATTENDANTS.

To the Editors of THE LANCET.

SIRS,—Would any of your readers kindly tell me what are the usual duties of a surgery attendant in a general practice and the usual salary?

I should also be glad to know if anyone has tried army dispensers in the surgery, and whether they were a success, and what salary was given.

I am, Sirs, yours faithfully,

March 5th, 1901. MEDICUS.

SECRET COMMISSIONS AND THE MEDICAL PROFESSION.

A MEDICAL man residing in one of the largest towns in the North of England has sent us the following circular which he received from a firm of surgical appliance makers in the town:—

> DEAR SIR,—In order that patients needing surgical apparatus may obtain the greatest possible comfort and support we adapt every appliance to the special requirements of each particular case. We do not, therefore, supply such apparatus wholesale, but allow the profession 20 per cent. discount, being the difference between the wholesale and retail prices. The patient is in all cases required to pay cash and is charged exactly the same whether recommended by a medical man or not. This method, whilst a saving of time to the medical attendant, ensures greater comfort and security to the patient. Any cases you may send us shall have our careful attention; a note or card should be sent with each case for identification.
>
> We are, faithfully yours,
>
> Discount remitted monthly. —— & ——.

We consider that this method of doing business is most reprehensible. It is neither more nor less than the offer of a bribe to a medical man to send patients to the firm in question instead of to the firm whose work they consider best. Such an offer is an insult and any firm adopting such methods must not be surprised at finding itself suspected of selling inferior goods.

CONSULTATIONS WITH HOMŒOPATHISTS.

Medicus writes: "Would you please to state the rule respecting a medical man meeting in surgical or medical cases a general practitioner who is, or states that he is, a homœopathic practitioner. Is it correct for the medical man to meet the homœopath at all? Is it right for a surgeon to come in consultation and perform operations for him? I am not aware that there is a homœopathic consultant within any reasonable distance of the small town mentioned."

*** It is not right for a medical man to meet practitioners who follow homœopathic lines in consultation. The tenets of homœopaths are founded on a completely false conception of disease; there is therefore no common ground upon which medical men can meet them for any discussion which would be of advantage to the patient.—ED. L.

A Subscriber to THE LANCET *since 1886* is thanked for his information. The advertisement in question had already been investigated and suppressed by ourselves. It is not at all surprising that occasionally advertisements of this character should get into our columns, as their nature is always more or less disguised.

Enemy.—Under the circumstances detailed our correspondent is, in our opinion, entitled to the payment of notification fees. In our pamphlet dealing with the difficulties arising under the Notification Act, page 20 *et seq.*, the matter is fully dealt with.

Suspended Animation.—Cheyne's case of Colonel Townshend is quoted by Aytoun, in the "Lays of Scottish Cavaliers and Other Poems" in the introduction to a poem entitled Hermotimus.

Davoz Platz.—There is no such book, but the matter is one upon which our correspondent's medical adviser can give an opinion.

L. J. will find the information that he requires in the last Students' Number of THE LANCET, published September 1st, 1900.

B. D.—The householder is not responsible for medical attendance upon his servants unless he expressly offers to pay for it.

A. M. W. urges in strong language precepts which will be found in our columns *passim*.

J. R. P.—We cannot deviate from our practice.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

WEDNESDAY (13th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (14th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (16th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (11th).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Dr. R. J. A. Berry (Edinburgh): A Lantern and Microscopic Demonstration on the True Cæcal Apex: being an Attempt to Prove that the Vermiform Appendix is not a Vestigial Structure.

TUESDAY (12th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—Address:—Prof. S. Woodhead: Immunity. Prof. Wright (Netley) and Mr. T. J. Bokenham will take part in the discussion.

CHELSEA CLINICAL SOCIETY (Jenner Institute of Preventive Medicine, Grosvenor-road, Chelsea).—8.30 P.M. Annual Clinical Debate:—The Clinical and Pathological Relations of the Chronic Rheumatic and Rheumatoid Affections to Acute Infective Rheumatism.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (17, Bloomsbury-square, W.C.).—8 P.M. Mr. M. W. Allen and Mr. E. T. Brewis: Notes on some Essential Oils.—Mr. J. C. Umney: Copaiba of Commerce.—Mr. J. S. Ward: An Adulterant of Stramonium Leaves.

WEDNESDAY (13th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 P.M. Mr. J. Cantlie: Plague (illustrated with lantern slides). (All members of the profession are invited.)

THURSDAY (14th).—CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret-street, W.).—4.30 P.M. Annual Meeting. 8 P.M. Prof. H. L. Withers: Examinatians in their Relation to Mental Growth.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 P.M. Cases, &c. 8.30 P.M. Papers:—Dr. Edridge-Green: Evolution of the Colour sense.—Mr. T. P. Teale: On the Value of Peritomy in certain Cases of Iritis, Episcleritis, and Purulent Ophthalmia.—Mr. J. F. Bullar: Notes on a Case of Membranous Conjunctivitis.—Major H. Herbert, I.M.S.: (1) A Note on the Surface of the Normal Cornea; (2) Hypertrophy and Ossification of Tarsus.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Mr. F. Jordan, Dr. H. Macnaughton-Jones, and Mr. C. Ryall. Paper:—Mr. W. R. Williams: Pathology and Treatment of Uterine Tumours during the Nineteenth Century.

GOLDSMITHS' INSTITUTE CHEMICAL SOCIETY (New Cross, S.E.).—8 P.M. Dr. J. Eyre: Antitoxic Sera, their Preparation and Standardisation.

FRIDAY (15th).—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (Belgrave Hospital for Children, 79, Gloucester-street, S.W.).—6.30 P.M. Cases will be shown by Dr. G. Carpenter, Dr. W. Ewart, Mr. C. T. Dent, Mr. E. T. Collins, Mr. F. Jaffray, and Dr. E. Cautley. Paper:—Dr. H. Ashby (Manchester): On a Case of Congenital Acute Nephritis.

EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Papers:—Dr. N. P. Schierbeck (Copenhagen): The Enteric Fever Mortality in Copenhagen from 1828–1898.—Dr. J. T. R. Davison: The Effect of Sewerage and Water Supply upon the behaviour of Enteric Fever in Buenos Ayres.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

SUNDAY (10th).—SUNDAY AFTERNOON FREE LECTURES (South-place Institute, South-place, E.C.).—4 P.M. Mr. C. W. Thies: The Hospitals of London (with lantern illustrations).

MONDAY (11th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. P. Furnivall: The Pathology, Diagnosis, and Treatment of the various Neoplasms of Stomach and Intestine.
MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. T. C. Fox: Consultation. (Skin.)
WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Edwards: Rectal Stricture and Ulceration.

TUESDAY (12th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. S. Taylor: Consultation. (Medical.)
THE BROWN ANIMAL SANATORY INSTITUTION (University of London, South Kensington, S.W.).—5 P.M. Dr. J. Rose Bradford (Professor-Superintendent): The Protozoa in their Relation to Disease, with especial reference to the so-called Tsetse-Fly Disease of South Africa.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Dr. A. Macfadyen: The Cell as the Unit of Life.
LONDON TEMPERANCE HOSPITAL (Hampstead-road, N.W.).—2 P.M. Dr. P. Parkinson: Clinical and Pathological Demonstration.

WEDNESDAY (13th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. P. Furnivall: The Pathology, Diagnosis, and Treatment of the various Neoplasms of the Stomach and Intestine.
MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Berry: Consultation. (Surgical.)
LONDON THROAT HOSPITAL (204, Great Portland-street, W.).—5 P.M. Mr. Waggett: Diseases of the Accessory Sinuses. (Post-Graduate Course.)
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Mr. S. Boyd: Sugical Cases in the Wards.
THE SANITARY INSTITUTE, (Parkes Museum, Margaret-street, W.).—8 P.M. Discussion on Ventilation, Success and Failures of the Methods at present in use (to be opened by Dr. C. Child.)

THURSDAY (14th).—LONDON TEMPERANCE HOSPITAL (Hampstead-road, N.W.).—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration.
MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)
THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Lees: Demonstration of Selected Cases.
THE HOSPITAL FOR DISEASES OF THE SKIN (Stamford-street, Blackfriars).—3 P.M. Clinical Demonstration: Dr. P. S. Abraham.
WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Robinson: The Diagnosis of Abdominal Swellings.

FRIDAY (15th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. P. Furnivall: The Pathology, Diagnosis, and Treatment of the various Neoplasms of the Stomach and Intestine.
MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. D. Grant: Consultation. (Ear.)
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Major A. St. Hill Gibbons: Through the Heart of Africa from South to North.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1900, which was completed with the issue of Dec. 29th, and the Title-page to the Volume were given in THE LANCET of Jan. 5th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1900, bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s.*, by post 2*s.* 2*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

The Hunterian Lectures

ON

THE TOPOGRAPHICAL ANATOMY OF THE ABDOMINAL VISCERA IN MAN.[1]

Delivered before the Royal College of Surgeons of England on March 4th, 6th, and 8th, 1901,

BY CHRISTOPHER ADDISON, M.D. LOND., F.R.C.S. ENG.,

PROFESSOR OF ANATOMY AT THE UNIVERSITY COLLEGE, SHEFFIELD.

LECTURE I.

Delivered on March 4th.

MR. PRESIDENT AND GENTLEMEN,—I thank you very much for the honour you have done me in electing me to deliver this course of lectures. I desire also, at the beginning, to express my warmest thanks to Dr. T. Claye Shaw and the resident medical officers of the London County Asylum, Banstead, and to Mr. Waters (the master), Dr. L. G. Hunt, and the resident medical officers of the Fir Vale Workhouse, Sheffield, for the very liberal manner in which for long periods they allowed me, with every possible assistance, to work in the mortuaries of these institutions. I am also much indebted to Dr. Leonard Giles of Scarborough for help with the appendix tables; also to Mr. A. M. Connell, the demonstrator of anatomy at University College, Sheffield, who throughout the preparation of the illustrations special to these lectures rendered me a constant and generous assistance which cannot be acknowledged too sincerely.

PURPOSE OF INQUIRY.

With the advance of medical and surgical science, especially as regards the operations of surgery on the abdomen, the topography of the abdominal viscera becomes of increasing importance. Any method of determining the position of the underlying parts should be as simple as possible, it should be convenient of application and should be applicable to a body of any size or condition, and it should, withal, as far as possible, make use of those terms of abdominal topography which have become established by custom and with the least possible disturbance of their present signification. Many accurate and extended measurements of the abdominal organs have been published at different times; but these, though exact in themselves, do not necessarily enable us to form an adequate anticipation of the shape or position of particular organs, if they themselves, or adjoining ones, abdominal or thoracic, are enlarged or diminished in size or altered in position through any cause whatever. The condition of an organ may be ascertainable on superficial examination, but in many cases this does not carry with it any exact information as to what we may expect to meet with in the neighbouring parts. These lectures embody the results of an inquiry into the topographical anatomy of the abdominal viscera in man. The work falls into two parts: (1) that dealing with the relations of the viscera to the surface of the body; and (2) that dealing with their relations to one another.

With regard to the first part, it is to be remarked that the methods of mapping out the abdomen at present in general use are open to certain objections, for the reason that the lines employed to divide the abdomen transversely are drawn at distances from one another which are variable and that the variations are not determined by the dimensions of the body. The points, especially, between which the upper transverse abdominal line is drawn are so variable in their level that in some cases the two transverse abdominal lines come very near together, leaving a large part of the abdomen above them not mapped out; whilst in other cases they may be far apart, and, moreover, it often happens in fat subjects that the points (such as particular rib cartilages) between which the upper transverse line is drawn cannot be accurately determined, and frequently the line if drawn correctly is not horizontal. The distance between the two transverse lines is usually much less than the distances above or below them, to the sternum and pubes respectively. Professor Cunningham[2] gives the average distance between them as 2·7 inches; the average depth of the costal zone, above the upper line, as six inches; and of the hypogastric zone, below the lower line, as five inches. Now six inches is too great a length without a guiding line in the costal zone, considering the very important structures contained in that region, if a line can be found therein which possesses a fairly constant significance. It has therefore been sought, first, to elaborate some system of abdominal surface-marking which shall be independent of variable surface points and which, whilst retaining those points as adjuncts, shall be unvarying and uniformly-proportioned to the size of the trunk; which shall be easily determined and in which the lines used to divide the abdomen shall be possessed of such constancy both in regard to the bony skeleton and the viscera that the lines themselves become reliable as landmarks.

With regard to the second part, it is of great clinical importance that in any case not only the position of any organ should be recorded, but that of all others in its neighbourhood; for in this way only can we discover the degree of independence or of interdependence in the position of the various organs and the extent, if any, to which when they are enlarged or diminished in size or displaced they tend to cause alterations in the positions of the various neighbouring parts. And it is perhaps as important to determine that changes in the shape or position of any one organ do not tend to cause alterations in the position of a neighbouring one as to determine that they do. In the second part of this inquiry, therefore, the abdominal viscera have been carefully mapped out in relation to well-defined, uniformly-proportioned surface lines, and by studying and comparing a series of cases it has been sought to ascertain, as far as possible, the modes in which the abdominal viscera alter their position or are displaced, when they themselves, or the viscera in their neighbourhood, are enlarged or diminished in size or pressed upon by the neighbouring parts.

DELIMITATION OF THE REGIONS OF THE ABDOMEN (FIG. 1).

In all examinations the subject was laid flat on the back, the legs extended in a straight line with the trunk, the arms drawn evenly down by the sides, and the head resting extended on the table. The abdomen is divided vertically by three lines—a median line and two lateral lines. The lateral lines are drawn vertically upwards, one on each side, through a point midway between the anterior superior iliac spine and the middle line, in a line drawn transversely across between the two anterior superior iliac spines. The median line is very useful both for the equal division of the abdomen and for purposes of measurement. The method for determining the lateral lines is more accurate than by taking the mid-point of Poupart's ligament, for that is a point which is not easy exactly to determine. Lines drawn obliquely upwards, such as those used by Professor Macalister,[3] from the spine of the pubes to the eighth costal cartilage seem objectionable because of the variations of the eighth costal cartilage and because the lines divide the abdomen unequally. The body is divided transversely by lines drawn across through points a quarter, a half, and three-quarters of the way along a line drawn from the upper border of the pubes to the supra-sternal notch. The uppermost transverse line passes across the thorax, as a rule 3·2 centimetres above the lower border of the body of the sternum. We are not further concerned with it. The upper transverse abdominal line, half-way from the pubes to the supra-sternal notch, is spoken of as the line E, F, and the lower transverse abdominal line—a quarter of the way—as the line C, D.

My purpose in selecting the transverse lines described was simply that of obtaining easily-found, equidistant points for the purpose of measurement and I was not prepared for the regularity of position in regard to the vertebræ and other structures which especially the upper line E, F, has been found to possess. It corresponds almost accurately to the disc between the first and second lumbar vertebræ, and cuts the junction of the eighth and ninth costal cartilages at the tip of the ninth. The lower line, C, D, practically corresponds

[1] The full details of the research on which these lectures are founded have been published in the Journal of Anatomy and Physiology, vols. xxxiii., xxxiv., and xxxv., and the author wishes to express his best thanks to the editors of that Journal for those illustrations which are reproduced in these lectures.

[2] Delimitation of Regions of Abdomen, Journal of Anatomy and Physiology, 1893.

[3] Text-book of Anatomy.

with Cunningham's intertubercular line drawn across between the two tubercles on the outer aspects of the iliac crests, and passes, on an average, five centimetres above the anterior superior iliac spine and 3·5 centimetres below the highest point of the iliac crest. The consequence of this division of the abdomen, as will be seen on reference to Fig. 1, is that there are right and left epigastric, umbilical, hypogastric, iliac, lumbar, and hypochondriac regions, with the hypochondriac regions, as a rule, wholly beneath the costal cartilages. This strict limitation of the hypochondriac region will not, I think, be seen to possess any disadvantage, whereas the increase of the lumbar region is to be desired.

METHOD OF EXAMINATION.

For obtaining the maps of the viscera the bodies of 40 subjects taken consecutively were examined in the fresh state, with the exception of two control bodies which were hardened before examination by the injection of 5 per cent. of formic aldehyde solution. In all but a few cases the examination was made within 30 hours after death.

Tables were prepared in which the time after death was noted, and the condition of the nutrition of the body in such general terms as "emaciated," "fair," "good," or "fat," and any special pathological or other condition or obvious displacement or distension of organs were described, and on which, later, the state of the various viscera whether soft or firm, was specially mentioned. On the tables also were recorded the age, sex, causes of death, stature, the dimensions of the trunk in various directions, the distances from one another of the various bony and other surface points and their relations to the lines used to divide the abdomen, as well as many other general and particular facts.

The distances from the pubes to the supra-sternal notch were measured by drawing the tape tightly between these points. If the abdomen was convex between them the half-way point was marked directly; if concave, the spot directly beneath the mid-point of the tape was taken, and at this point, after a small skin incision, a long steel pin was driven through the abdomen. This marked the level of the upper transverse line E, F. In a similar way the level of the quarter-way line C, D, was determined and a second pin driven through the abdomen. The position of the lateral lines was then determined and four more pins were driven through the abdomen, one in each lateral line in the planes of C, D, and E, F.

FIG. 1.

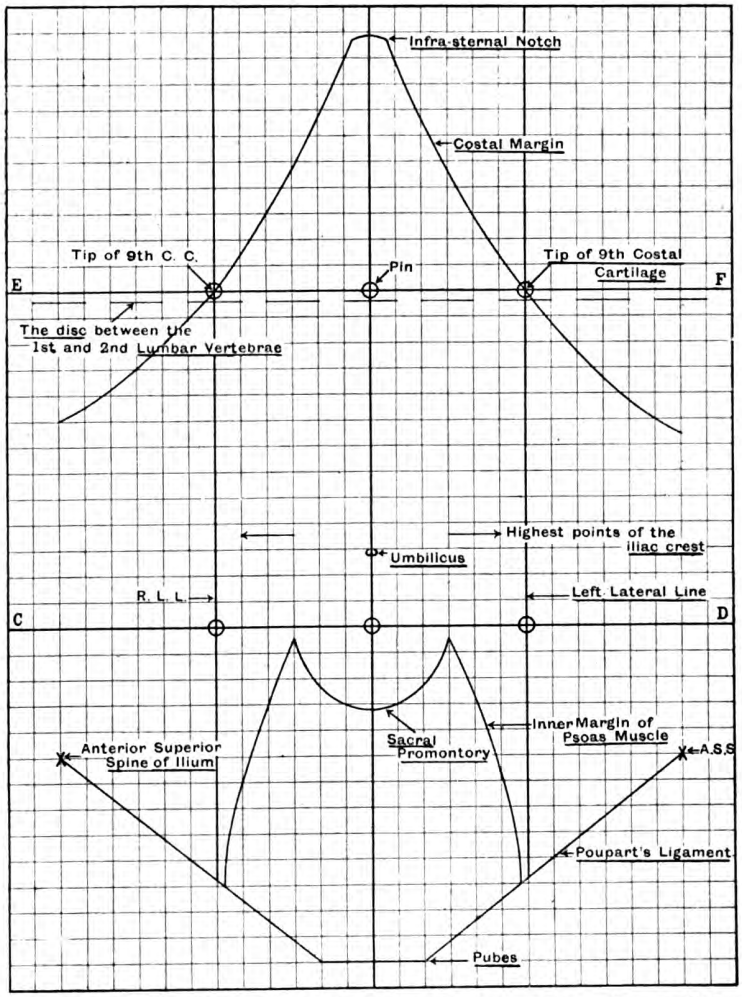

Diagram showing the average position of the landmarks whereby the abdominal regions are limited. E, F, is drawn transversely half-way and C, D, a quarter-way between the pubes and the supra-sternal notch. The vertical lines used are the middle line and two lateral lines, one on each side, drawn vertically upwards through a point midway between the anterior superior iliac spine and the middle line.

If the abdomen between the anterior superior iliac spines was convex forwards beyond them, or unequally distended as in the case of a distended cæcum, the measurement between the spines was taken on a forward projection and was confirmed on opening the abdomen. After opening the abdomen the distances vertically upwards from Poupart's ligament along the lateral lines, from the anterior superior iliac spines, and from the highest point of the iliac crests to the costal arch or ribs, and other measurements, were checked as they were come to, and a drawing of the costal arch was made. For this drawing the distances of the tips of the different cartilages from the infra-sternal notch were measured along the costal margin; the transverse width

of the arch in the plane of E, F, and between the tips of the tenth costal cartilages, or other suitable points according to the arch, was also taken, and the differences in level and width, if any, of the points cut by the lateral lines as they impinged on the arch and the line of E, F, as it passed transversely. At the conclusion of the examination the relations were obtained of the upper medium pin to the disc between the first and second lumbar vertebræ, and of the lower pin to the aortic bifurcation, to the disc between the fourth and fifth lumbar vertebræ, and to the pelvic brim in the middle line. Finally, the brim of the pelvis, as measured between the inner margins of the psoas muscles, was fully drawn in its relation to C, D, and Poupart's ligament. These different bony and other surface and deep points, with the lines used to divide the abdomen in their appropriate positions, were drawn on the life-size scale on large sheets ruled in centimetre squares in which the outlines of the various viscera were progressively filled in.

In this way a complete map of the superficial and deep points in their relations to the lines of division of the abdomen was obtained and the outlines of the viscera projected on to the surface in relation to the lines adopted could—if the lines were not found convenient—be transferred to any other system of surface divisions whatever. The steel pins used to transfix the abdomen are 14 inches in length, with a long, well-sharpened point and an expanded head, and as thin as is consistent with absolute rigidity. They were driven in with the utmost care and at right angles to the table. They were made so long in order that, as they project for some inches from the front abdominal wall, the slightest obliquity might be obvious. For it is clear that even a small degree of obliquity in the case of a thick abdomen would lead to the point of the pin entering the back wall a centimetre or more higher or lower as the case might be. It was, however, done so carefully that I think in the whole series the degrees of error will fairly correct one another. The median and lower lateral pins fasten themselves in the vertebræ and iliac bones respectively. The upper lateral pins which passed free of or through the costal cartilages, as the case might be, were driven into the table. The measurements of a part were taken immediately from a pin at the point of its transfixion with a stiff steel measure. The abdomen was opened by a median incision, and by lateral incisions in the planes of C, D, and E, F, as far as the pins, or farther outwards if necessary.

I need not detain you to describe the order of the examination of the parts, which necessarily varied somewhat in different cases. No parts were disturbed before being measured and drawn, and they were cut away piecemeal as required to expose the parts beneath. A complete map of the viscera and of the lines of the peritoneal attachments was at length obtained. Subsidiary drawings of peritoneal pouches and other parts were made as required, and at the end of the examination the parts at the back of the abdomen and the brim of the pelvis were filled in.

Two or three of the large ruled sheets were generally required for the records, and the examination, which occupied, as a rule, four hours or more, was often very difficult and laborious. Although 40 cases are presented and averages drawn from them, it is fully recognised that in the case of many of the averages much more extended observations are necessary.

SURFACE POINTS AND MEASUREMENTS.

The matter to be dealt with compels me sometimes to state averages and to give measurements, but I will try to trouble you as little as possible with figures. They have been fully analysed and set forth in the different tables.

There were 12 females examined and 28 males. The average age was 45½ years. The average height was five feet three and three-quarter inches, or about 160 centimetres. The average distance from the pubes to the supra-sternal notch was nearly a third of the height—viz., 52 centimetres, and this distance varied very little. In 65 per cent. of the cases the distance did not vary more than two centimetres from the average. The greatest distance was 58 centimetres (in a male five feet five inches in height), and the least distance was 46 centimetres. This occurred in two cases, in a male four feet six and a half inches and in a female four feet seven inches in height. The distance from the pubes to the supra-sternal notch, therefore, is not a very accurate guide to the height of the individual.

The average length of the abdominal part of the trunk was 35·8 centimetres, leaving the manubrium and body of the sternum a length of 16·2 centimetres, or about one-tenth (9·8 per cent.) of the total height of the individual. The average distance between the transverse lines was 13 centimetres or a little over five inches. (Refer to Fig. 1.) The infra-sternal notch averaged 9·8 centimetres or about four inches above the upper transverse abdominal line. The maximum distance recorded was only 11·5 centimetres, and it occurred only in two cases; the minimum distance, eight centimetres, was only recorded in two cases. In such a diversity of subjects, with so different characters of the chest and abdomen, this variation is small and would seem to indicate the serviceableness of the line E, F.

The upper transverse abdominal line (E, F).—The mid-point of the distances from the pubes to the supra-sternal notch was taken quite regardless of the condition of the body, whether fat or thin, with the abdomen or chest distended or not, and the regularity of the position which it is found to occupy is of much interest. Its average position was opposite the body on the first lumbar vertebra, 0·33 centimetre above the disc between the first and second lumbar vertebræ. The variations from the disc were very small; in 36 cases, or 90 per cent., the pin was less than two centimetres from it. The maximum distance away (2·5 centimetres) occurred only in one case. Considering the very important structures which overlie the vertebral column in this neighbourhood this regularity in its position renders the surface line of much utility. The line passed across in the average at the tip of the ninth costal cartilage on the right side and a little above it on the left. We find on comparison that the tip of the ninth costal cartilage had a somewhat wider excursion in relation to E, F, than the first lumbar inter-vertebral disc had. (Fig. 2.) In 30 cases, or 75 per cent., the level of the tip of the cartilage was not more than two centimetres from that of the surface line, and it happens that in a like number of cases it had an equal variation in regard to the first lumbar inter-vertebral disc. The greatest distance of the tip of the ninth costal cartilage from the surface line was three centimetres in two cases; there were, however, five cases in which it varied from three centimetres to five centimetres from the disc. The point of importance, however, is that we often cannot definitely locate the tip of the ninth costal cartilage until the skin and muscles have been reflected, whilst the surface line is found in a moment.

The lower transverse abdominal line (C, D).—In the region of the abdomen across which the lower—quarter-way—transverse line passes the bony points are more stable and the necessity of a transverse line apart from them is not pressing. However, the line C, D, occupied a very constant position in relation to the anterior superior iliac spines. In 35 cases, or 87·5 per cent., it did not vary more than one centimetre from its average distance of five centimetres above the spines. It averaged 3·5 centimetres lower than the highest part of the iliac crest, and in this relation also the variations were small, for in 31 cases, or 77·5 per cent., the variation was not more than one centimetre from the average. If we combine these last two statements it appears that the rise in the ilium from the anterior superior iliac spine to the highest part of the crest, as the subject lay on the table, was 8·5 centimetres, or nearly three and a half inches. The tilt of the vertebral column varies, and the part which, looked at from the front, would be selected as that where the spine definitely bends backwards into the pelvis, is variously the lower border of the fifth lumbar vertebra, the upper border of the sacrum, or the disc between these bones. This part in any case in the tables is called the sacral promontory. The line C, D, corresponded to the fifth lumbar vertebra 3·2 centimetres above the promontory. We will not stay to analyse the variations. They were a little wider than its variations in regard to the crest and anterior superior spines of the ilium. The average position of the *umbilicus* was about an inch (2·7 centimetres) above C, D. It varied from the same level up to 5·5 centimetres above, but in 21 cases, or 52·5 per cent., the variations were not more than one centimetre from the average. In 30 cases, or 75 per cent., the umbilicus was not more than one centimetre away from the level of the highest point of the iliac crest; but in the remaining cases the variation was as much as six centimetres. We may fairly say that the lower transverse abdominal line is as regular in its position in regard to the bony points as the umbilicus is.

The width across the *costal arch* in the plane of the line E, F, varied too much for the figures to be of any value, and it is evident that except at the upper part

of the arch it is of little use to describe the deep parts as being so much internal to, coinciding with, or as so much beneath the costal margin. The average distance between the two anterior superior iliac spines was 23·8 centimetres and the width across the body in the plane of C, D, was 29 centimetres. In rising five centimetres in level the iliac crests therefore had widened out one inch on each side. There were eight cases in which the distance between the anterior superior iliac spines was 22 centimetres or less, of which two were females. The smallest measurement, 19 centimetres, occurred in a man five feet four and a half inches in height and 52 centimetres from the pubes to the supra-sternal notch. There were seven cases, all males, in which the distance was 26 centimetres or more, up to 28 centimetres in three cases, the individuals in these being respectively 5 feet 2½ inches, 5 feet 10½ inches, and 5 feet 5 inches in height, and 55, 55, and 58 centimetres from the pubes to the supra-sternal notch respectively. The distance vertically upwards from the anterior superior iliac spines to the nearest part of the costal arch, which was almost invariably the tenth costal cartilage, ranged from 8·5 centimetres to 18 centimetres. This is another proof of the variableness of the costal arch; although it should be said that in 23 cases on each side the variation was not more than one centimetre from the average. In 17 cases the distance on the right side exceeded that on the left, and in five cases only was it less. In 16 cases, or 40 per cent., the tenth costal cartilage did not articulate with the ninth, and in most of these cases the twelfth rib was noticed to be small and difficult to feel. The average distance from the highest part of the iliac crest vertically upwards to the nearest rib was 4·8 centimetres, and 4·7 centimetres on the right and left sides respectively. The part met with was usually some part of the eleventh rib. In 33 cases the distances on the two sides were practically equal, and in five cases that on the right exceeded that on the left. The measurements ranged from three centimetres to eight centimetres, which is a wide variation in view of the small distance involved. It is interesting to notice that in the average the lateral lines, drawn vertically upwards, and the line E, F, drawn transversely, met the costal margin in identical points on each side—viz., the tip of the ninth costal cartilage.

AVERAGE POSITION OF THE VISCERA IN REGARD TO THE SURFACE (FIGS. 2 AND 3).

In regard to the surface marking of the viscera it is better that we should have clearly in our minds the general position of certain important points around which the parts can be arranged than that we should burden our memories with detailed measurements of individual organs.

A. The upper transverse abdominal line E, F.—Firstly, this practically bisects the stomach over the middle line and the pylorus a little further to the right. Reference to the outlines shows that in 29, or 72·5 per cent., of the cases the line was absolutely reliable as a guide to the pylorus, passing either through it or at one of its margins. Secondly, it represents at its intersection with the middle line the lower border of the liver. This observation, however, is perhaps of no special importance since the lower border of the liver can usually be made out by palpation and percussion. Thirdly, at its intersection with the right lateral line it marks the place where the gall-bladder overlies the duodenum, and, when the liver is not enlarged or displaced downwards, it usually passes a little above the highest part of the ascending colon. Fourthly, about half-way between the middle line and the left lateral line it marks the upper border of the duodeno-jejunal flexure and the upper end of the root of the mesentery. The duodeno-jejunal flexure is perhaps the least moveable part of the small intestine, for the outlines of the duodena on the reduced scale show that in 34, or 85 per cent., of the cases it was not more than two centimetres away from the surface line, one way or the other. Fifthly, it follows from what has been said from its relation to the pylorus that the line almost invariably crosses some part of the head of the pancreas, usually about the upper third. Moreover, in the left lateral line, the anterior border of the pancreas in 70 per cent. of the cases was within two centimetres of this line. In fact, it may be said that in the left lateral line at this level are found, in the absence of manifest distensions of the stomach or intestines, the greater curvature of the stomach as it passes beneath the costal arch, the anterior border of the pancreas with the attached transverse meso-colon, and the upper border of the transverse colon itself. Sixthly, further to the left beneath the ribs the line crosses the basal surface of the spleen.

B. The lower transverse abdominal line C, D.—First, it represents at points half-way between the middle line and the lateral lines the place where the psoas muscles diverge from the lumbo-sacral promontory, and, on the left side, the line passes a little above the inner attachment of the meso-sigmoid; secondly, in the right lateral line it marks the upper border of the ileo-colic junction; thirdly, in the left lateral line it marks the inner border of the descending colon just above the commencement of the meso-sigmoid.

C. A plane across the abdomen midway between the transverse lines corresponds nearly enough in each lateral line to the lower pole of the kidney, passing a little above that of the right and a little below that of the left. In the right lateral line, also, it indicates the commencement of the transverse meso-colon, and in the middle line the root of the mesentery as it crosses from left to right.

A few points concerning the surface markings of individual viscera may be mentioned.

1. *The stomach.*—After the œsophagus has pierced the diaphragm it frequently passes downwards and to the left for a short distance before opening directly into the stomach. The position found to be occupied by the cardiac orifice, beneath the seventh costal cartilage about an inch from its junction with the sternum, agrees with that generally given. The stomach passes from the cardiac orifice upwards and to the left into the vault of the diaphragm and reaches its summit in the left lateral line just below the fifth costal cartilage. By the summit of the stomach is meant that part which is highest *in situ*; for if the stomach be removed from the body and distended it is often found that that part which was previously the highest is now not so, but a portion of the stomach which was previously on a posterior plane.

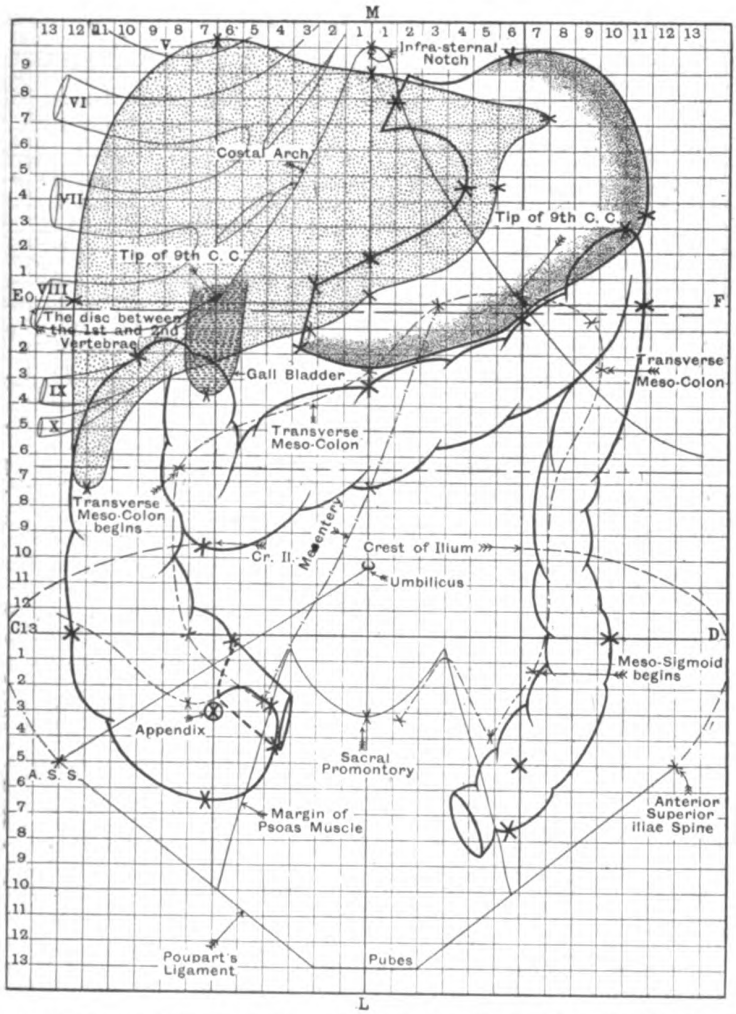
2. *The duodenum.*—The duodenum may be roughly mapped out by constructing a parallelogram which has for its sides the middle line, the line E, F, the right lateral line, and the line drawn transversely half-way between the transverse abdominal lines (see Fig. 3). The upper, outer, and lower sides of the parallelogram respectively bisect the first, second, and third parts of the duodenum, whilst the fourth part inclines to the left of the inner side of the parallelogram. It is, of course, to be remembered that the duodenum only commences about an inch to the right of the middle line. In the right lateral line the second part of the duodenum reaches nearly down to the highest part of the iliac crest.

The root of the *mesentery* extends from a point midway between the middle and left lateral lines in the plane of E, F, downwards and to the right to the inner margin of the right psoas muscle at a point midway between the planes of the anterior superior iliac spines and of the C, D, rather nearer to the right lateral than the middle line. The *lower end of the ileum* is commonly firmly fixed in its position and the upper border of the ileo-colic junction is marked by the intersection of the right lateral and lower transverse abdominal lines. The *root of the appendix* generally lies near the lower border of the ileo-colic junction in the right lateral line about the level of the lower end of the mesentery. It is usually an inch or so below the mid-point of a line drawn from the anterior superior iliac spine to the umbilicus. The lowest point of the *cæcum* is usually in the right lateral line well below the level of the anterior superior iliac spine. A line drawn vertically upwards from the right anterior superior iliac spine represents accurately enough the outer border of the *ascending colon*. The inner borders, both of the ascending and descending colon, are more constant in their position as regards the surface than the outer borders lying generally a little outside either lateral line. The *transverse colon* as it crosses the middle line is variable both in its shape and position. It is, in a general way wholly in the umbilical regions, and, in the average, its lower border reaches to midway between the transverse abdominal lines. The first (or firmly attached) portion of the *sigmoid colon* begins a little outside the left lateral line just below the level of C, D, and the freely moveable part, which has a long mesentery passing upwards along the left pelvic brim, begins in the left lateral line about the level of the anterior superior iliac spine.

The solid viscera.—What has been said of the duodenum indicates the position of the head of the *pancreas* and we have seen that the line E, F, represents the anterior border of the pancreas in the left lateral line. Nothing need be said

here of the surface-marking of the *liver* except that its left extremity usually reaches a little beyond the left lateral line behind the sixth costal cartilage and its highest part on the right side is behind the fifth costal cartilage in the right lateral line. The upper transverse abdominal line E, F, crosses the *right kidney* at the junction of its upper with its middle thirds and the *left kidney* at the junction of its upper two-fifths with its lower three-fifths, and the lateral lines traverse the kidneys vertically about a third of the way from their inner to their outer borders. The highest part of the *spleen* in front is marked by a point in the left lateral line behind the sixth costal cartilage.

FIG 2.



Outline figures showing the average position of the abdominal viscera on a centimetre scale; reduced to 0·36 natural size. The lines of the peritoneal attachments are also shown. The crosses (× ×) indicate the position of the various "points" referred to in the text. The lettering is the same as in Fig. 1. (From a drawing by C. W. Smith.) *Note.*—The arrow showing the tip of the ninth right costal cartilage should have been drawn pointing to the intersection of E, F, and the right lateral line. The lower border of the stomach and the upper border of the transverse colon in the left lateral line should have been each represented 0·5 cm. lower down.

The further details of this part of the subject are perhaps more usefully set forth in the various tables and illustrations than in any other way—especially in Figs. 2 and 3. We will pass on to consider the positions and displacements of the different viscera in detail, commencing with the stomach.

THE STOMACH.

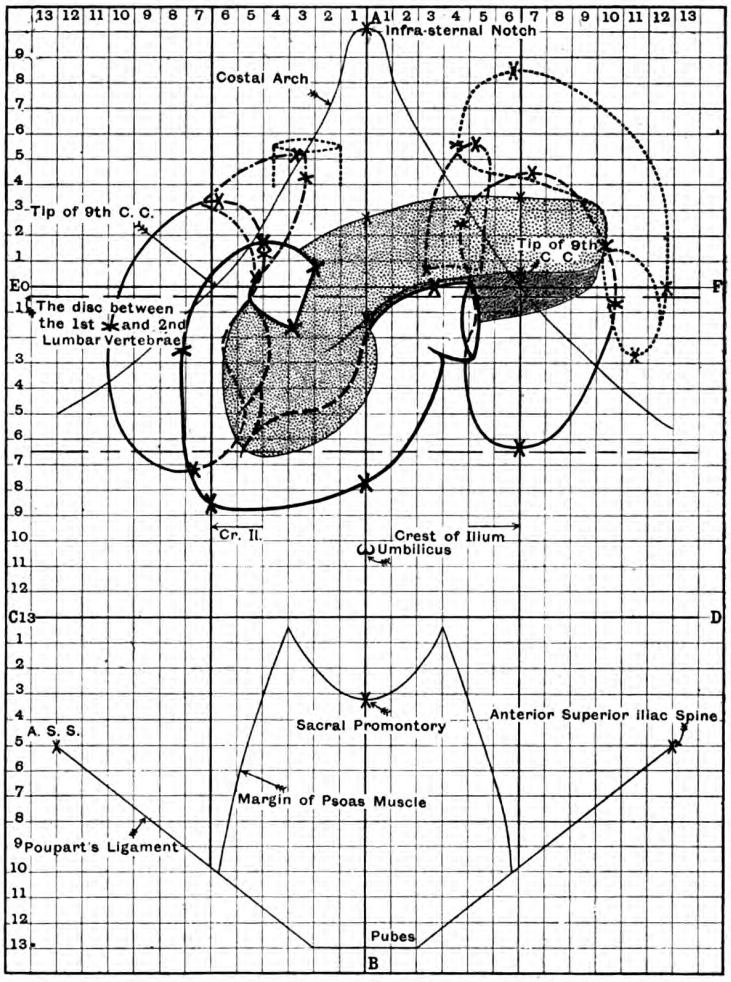
The relations of the stomach anteriorly to the liver and transverse colon are best referred to as we consider its different displacements. The part of the stomach which is in immediate relation with the anterior abdominal wall is very variable in its extent and position. It may apparently most certainly be approached in the plane of the upper transverse line about midway between the middle and left lateral lines.

1. *Variations of the shape of the stomach* (Fig. 4).[4]—The outline of the stomach as seen from the front does not necessarily indicate what would be its shape if it were removed from the body and filled. Its shape is no doubt in a great measure determined by the pressure of adjoining viscera, but allowing for this the cases do perhaps furnish some indications of certain natural varieties in shape. The first variety consists of a type of stomach usually not of large size and characterised by a long cylindrical portion passing to the pylorus. It is, perhaps, the commonest. It was well marked in 11 cases and less so in six others, or in 42·5 per cent. of the total cases. Sometimes the shape was plainly due in a large measure to the pressure of the transverse colon. We remark that the stomachs of this type contain amongst them all those in which the stomach was highly placed and, coincidently with this, all those in which a distended transverse colon passed highly upwards in front of the stomach. The frequency with which this occurred—viz., in nine cases, or nearly one in four—is, I think, of clinical

[4] This figure, along with others, will appear with the second lecture and will contain selected examples of the outline of the stomach from selected cases to illustrate the different points referred to.

interest. In other cases also of this group the transverse colon was distended, though not in front of the stomach. It is clear that a distended transverse colon was associated very commonly with this shape of the stomach and presumably was to some extent responsible for it. It is, however, open to suggestion, seeing, for instance, that the stomach from Case 1 (which was a good example of this type) still retained its shape after removal from the body and being filled with agar jelly, whether this type of stomach, being mostly small, does not, if the colon becomes distended, invite the bowel, as it were, to seek its additional room in the upper part of the abdominal cavity, so that a distended colon high in the abdomen may not alone be the cause, but perhaps, to some extent, the consequence, of a stomach this shape. Eight of the subjects with this type of stomach were emaciated and had suffered from long-standing disease. As to the second variety, six of the stomachs show very well, and three others imperfectly, evidence of a constriction somewhere in the cardiac portion that would no doubt have been permanent. The constriction, when present, tends to be about half-way along the left border of the greater curvature. The interior of these stomachs was not examined. In regard to a third variety, eight of the stomachs which were apparently chronically distended were almost evenly cylindrical. They will be referred to again. A quadrilateral shape of the stomach was presented in some cases (No. 16) and there were of course many types intermediate between those described.

FIG. 3.



Outlines of the deeper abdominal viscera constructed on the same plan as those shown in Fig. 2. (From a drawing by C. W. Smith.)

2. *Variations in the Position of the Stomach.*

The cardiac orifice. — The general position of the centre of the cardiac orifice was two centimetres below the infra-sternal notch and one centimetre from the middle line. It had, however, an excursion of seven centimetres about the infra-sternal notch, from six centimetres below to one centimetre above. In three instances only (Nos. 4, 12, and 34) the centre of the cardiac orifice was above the infra-sternal notch. The first patient had died from phthisis; the stomach was large and full; there is no record of distension of the rest of the intestine, and the transverse colon was low and tortuous. The second case was one of pneumonia; the jejunum and cæcum were very distended; the transverse colon was full and the splenic flexure reached high up into the vault of the diaphragm to the left of the stomach. The third case was one of phthisis with some tuberculous peritonitis; the small intestines were very distended; the transverse colon was in its normal position; the liver was very large and extended to the left across the stomach overlapping the spleen. Taking the extreme cases the other way; there were six cases in which the centre of the cardiac orifice was four centimetres or more below the infra-sternal notch (Nos. 7, 15, 18, 27, 30, and 35). The first was a case of right pneumothorax, with the liver and stomach pushed down. The second case presented a large intra-thoracic tumour, with a similar displacement of the stomach and liver. In the third case the costal arch was narrow but there is nothing recorded from the thorax to account for the low cardiac opening; and in this case, although the upper border of the stomach was lower than usual, the lower border was higher than the average, being supported by distended small intestines above a low transverse colon. In the fourth

case there was a large secondary sarcomatous growth in the thorax, especially on the left side; the transverse colon was distended and low down. In the fifth case there was no special factor recorded; the small intestines were distended, but the transverse colon was low down, running across the pelvic cavity. The last case was one of advanced phthisis, and in this, as in the third case, the lower border of the stomach was higher than the average; but the cause of the displacement of the upper border downwards was quite obvious, for a huge transverse colon had passed up in front of the stomach, pushing the liver over to the right and insinuating itself between the stomach below and the diaphragm above.

Conclusions.—The chest conditions, as we should anticipate, are the most important in producing downward displacements of the cardiac portion of the stomach, even against considerable intestinal distension below. Upward displacements are usually associated with distension of the intestines and often with a large transverse colon passing upwards in front of the stomach. On the other hand, distension of the intestines, even when there is absence of any obvious thoracic opposition, is not always associated with a raised cardiac orifice. The distension of the transverse colon, in fact, in the last case was the actual cause of the downward displacement of the cardiac orifice. A comparison of the relative levels of the cardiac and pyloric orifices does not reveal any point worth noting.

The pylorus.—If the diagrams on Fig. 4 be consulted it will be seen that in 29 cases, or 72·5 per cent., the line E, F, passed either across some part of the pylorus or within 1·5 centimetres of one of its margins. 1. *Vertical displacements.*—There were 29 cases in which the upper border of the pylorus was in the plane of, or above the level of, E, F, and 11 cases in which it was below. In five of the first group of cases the pylorus was more than three centimetres, up to 6·5 centimetres, above E, F. These cases we will call those of "high position." In six of the last group of cases the pylorus was more than two centimetres, up to 6·5 centimetres, below E, F. These we will call the cases of "low position." The total excursion of the pylorus about the plane of E, F, was 13 centimetres. In four of the five cases of high position the colon was distended and passed upwards to a variable height in front of the stomach, and in the other case (No. 5) a distended jejunum pressed the stomach up. In these cases also the liver was pressed upwards and to the right by the distended intestines, and was noted to be small in three of the cases. Five of the six cases in which the pylorus occupied a low position presented a liver either large or displaced downwards. In two cases there was a large lardaceous liver; in one case an immense liver was pushed downwards by a large growth filling the right side of the thorax; in another case the liver was displaced downwards by a right pneumothorax, and in the remaining case there was a large and somewhat low nutmeg liver. In all these cases the stomach was distended and vertically elongated. In all of the cases there was a low prolapsed transverse colon, but in three of them there was a considerable interval between the upper border of the prolapsed colon and the greater curvature of the stomach, in which the stomach was supported behind the mesocolon by small intestines.

Low positions of the stomach.—Those cases in which the pylorus reached low down in the abdomen include amongst them most of those in which the stomach, as a whole, was low down, but not all. It will be convenient to take at this place those other cases in which the stomach itself was lowly situated whilst the pylorus was not depressed. A stomach may be full—in fact, distended—without coming appreciably lower in the abdomen, as outlines 9, 10, 16, 23, 28, and 29 on Fig. 4 show. It appears to be the stomach which is vertically elongated (however that elongation may have been produced) which is found low down, and its low position is usually associated with a liver enlarged or displaced downwards and with a low or prolapsed transverse colon. In Case 38 all the parts were loaded with fat and the gastro-intestinal canal was very capacious; the stomach was very flabby and of immense size and came 10 centimetres below E, F, in the middle line. The liver in this case was not enlarged and occupied its normal level, and the pylorus was at its usual height. The transverse colon ran along the lower border of the stomach to the left lateral line, when it passed upwards beneath the stomach to its splenic flexure, which was situated above the level of E, F. In Case 39 the stomach was eight centimetres below E, F in the left lateral line. There was a large liver extending low down on the right side, but with only a thin flap overlying the stomach to the left of the middle line; a distended transverse colon passed across below the greater curvature of the stomach. In this case the upper border of the pylorus was situated in the plane of E, F, 0·75 centimetre to the right of the middle line. In Case 30 similar conditions prevailed, though they were not so exaggerated, and the transverse colon was prolapsed.

Conclusions.—1. From the foregoing cases it appears that a highly placed stomach is usually associated with the liver placed well up beneath the ribs, and often small, and with a highly-placed transverse colon, which in most cases also is distended. As regards the transverse colon, however, it appears that it may come upwards in front of the stomach without appreciably raising the whole stomach, merely pressing it backwards into the stomach bed. 2. A low position of the stomach—referring to the greater curvature—appears to be specially associated with the liver extending low down in the abdomen and perhaps enlarged and with a low transverse colon. But the transverse colon, by an increase in the length of its mesentery, may sink away from the stomach, which may be supported at its usual level by the small intestines behind the long transverse mesocolon. 3. The liver is clearly chiefly responsible for causing alterations in the level of the pylorus. When the liver extends low down in the abdominal cavity the pylorus is generally lowly situated, and *vice versâ*. Moreover, allowing for the fact that the part of the liver overhanging the stomach varies considerably in thickness, it appears that *mere distension of the stomach, apart from a low position of the liver, is not sufficient to produce material downward displacement of the pylorus.*

A Clinical Lecture

ON

THE TREATMENT OF TUBERCULOUS PERITONITIS.

Delivered at the Medical Graduates' College and Polyclinic on Dec. 19th, 1900,

BY I. BURNEY YEO, M.D., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL AND EMERITUS PROFESSOR OF MEDICINE IN KING'S COLLEGE.

GENTLEMEN,—I propose to call your attention in this lecture to the particulars of three successive cases of tuberculous peritonitis which were treated by a form of *medical* treatment which I shall describe to you and which I think merits your attention as the patients in all three cases made excellent recoveries.

The results that have of late years been obtained in the treatment of tuberculous peritonitis, as at present carried out, afford, I think, much cause for congratulation and satisfaction to the representatives of modern medicine. It would not be easy to point to any disease in which, as compared with 50 years ago, the prognosis has so greatly improved. Sir Thomas Watson, one of my distinguished predecessors in the chair of Medicine in King's College, in his well-known lectures, when referring to cases of this disease, says: "These are very unpromising forms of disease and it is seldom that we can do more than mitigate the most distressing of the symptoms, or retard, perhaps, the march of the disorder ..... do what we may, *in nine cases out of 10*, our best directed efforts will be disappointed." Much more recently Dr. Bristowe, in his "Text-book of Medicine," wrote of this disease in a scarcely less despondent tone. He says: "Tubercular peritonitis tends, as a rule, to a fatal result; at the same time there are good grounds for belief that recovery occasionally occurs." Even so recently as 1894 Professor Dieulafoy writes of this disease: "Death is almost always the consequence; a cure is, however, possible."[1]

How great an improvement has taken place in the treatment of cases of tuberculous peritonitis may be judged from the fact that statistics show that now over 50 per cent. of these cases recover, and there seems to be good reason to

[1] Manuel de Pathologie Interne, seventh edition.

hope that as modern methods of treatment become better known and earlier applied still more favourable results will be obtained. We doubtless owe some of this improvement to the vast progress which has been made in recent years in abdominal surgery, dependent on the better knowledge we possess as to the immunity with which operations on the peritoneal cavity may be undertaken provided it is protected from septic infection. But my object in this lecture is to show that progress has also been made in the *medical* measures which are applicable to the treatment of this disease We know much more now about the pathology and clinical history of tuberculosis than we did 25 years ago and our knowledge is daily growing more and more complete.

The teaching of Louis and his followers that tubercle of the peritoneum was never *primary*, but always *secondary*, to pulmonary tuberculosis has only recently been called in question, and strange to say this doctrine is still maintained in the most modern of our systems of medicine and we read there that "a primary tuberculous peritonitis is of very doubtful existence and the disease is probably never limited to the peritoneum. ..... Most commonly an eruption of tubercle on the abdominal serous membrane is secondary to pulmonary tuberculosis and caseating lymphatic glands in the thorax."[2] But Osler[3] has shown that this view is no longer tenable and that a tuberculous affection of the peritoneum is often primary. It was so in five out of 17 of his necropsies—i.e., in 30 per cent. And if this was the proportion in the fatal cases one might expect a much larger proportion in those that recover. This is a very encouraging fact from the point of view of therapeutics, as it must be far more hopeful to have to deal with an *uncomplicated* tuberculous peritonitis than to have to deal with tubercle of the peritoneum complicated with tubercle of other organs. Indeed, it would be very difficult to understand the success that has undoubtedly attended laparotomy in treating this disease if it were true, as has been taught, that tubercle of the peritoneum is almost invariably secondary to tubercle within the chest. Moreover, it has been shown that tubercle bacilli can pass through the wall of the intestine into the peritoneal cavity without attacking the former.

In answer to the question, "How does the tubercle bacillus reach the peritoneum?" Dieulafoy gives this reply: "Most frequently it enters by the *intestine* where it has been introduced in the food—infected meat, infected milk. The bacillus may attack the intestine first and the peritoneum next, but *absorbed by the superficial lymphatics* of the mucous membrane, it *may attack primitively the serous membrane*. This appears to have been proved by the recent experiments of Wesener and Cornil. ..... Debroklousky has demonstrated that the bacillus can pass through the walls of the intestine and reach the peritoneum without a primary lesion of the intestine."[4] This observation points to a very probable cause, and a preventable one, of many cases of tuberculous peritonitis—viz., the consumption of infected milk. In one of the cases which I have to relate to you the occurrence of this disease was believed to have been traced to the use of milk from a cow which was subsequently found to be tuberculous; and it was at least possible, if not probable, that infected milk may have been the cause in the other two. With these few preliminary remarks I will now ask your attention to the particulars of the three cases, the treatment of which I wish to bring to your notice.

CASE 1.—In the middle of June, 1898, a girl, 13 years of age, was sent into King's College Hospital, under my care, by Dr. Raymond Crawfurd, who had been attending her at the Victoria Hospital for Sick Children, and the diagnosis sent with the case was that it was one of tuberculous peritonitis and pleuritis. Besides the physical signs of an effusion of fluid in the right pleural cavity we had also in this case the symptoms of acute tuberculous peritonitis. The patient presented much abdominal swelling and tympany and much abdominal pain and tenderness; she was also much emaciated. It was also noted on admission that the cheeks were flushed, that the skin was hot and perspiring, the tongue dry and furred, and the breath offensive. The pulse was rapid, small, and compressible. There was dulness at the base of the chest on the right side for about a hand's breadth, with absence of breath sounds and absence of vocal fremitus. The abdomen, as has been said, was distended and painful and tympanitic all over, except in the flanks and the hypogastric region, where there was dulness which changed its position on moving the patient from side to side and which was no doubt due to the presence of fluid in the peritoneal cavity. There was also troublesome diarrhœa and the motions were offensive and contained undigested food. The temperature was of the hectic type and very characteristic of tuberculous disease. The chart for the first week after admission indicated that the daily range of temperature was as much sometimes as 6° F., the morning temperature falling to 97·2°, and the evening temperature rising to 103·2°. The previous history of this case pointed to a comparatively sudden onset. The family history was very good and the child had had no previous illnesses. She was quite well a month before admission into the hospital. At that time she began to complain of abdominal pains of a "griping" character which came on suddenly and "doubled her up" as her mother expressed it. The abdomen was observed to have become swollen and there was severe diarrhœa. The taking of food immediately brought on both pain and diarrhœa. It was also noticed that the child sweated freely at night. There could be no doubt that we had to do with a case of tuberculous peritonitis, very possibly due to the consumption of infected milk, and the pleural effusion was most probably also of tuberculous origin.

With regard to treatment the indications were clearly first to allay the pain and catarrhal irritation of the bowels, and secondly, to combat, if possible, the tuberculous infection. She was therefore ordered a mixture to be taken every six hours, containing in each dose 15 grains of salicylate of bismuth, 15 minims of spirit of chloroform, half a drachm of compound tincture of cardamoms and some mucilage and water, and to have milk diet. At the same time a liniment was applied to the abdomen consisting of three parts of opium liniment and one part of tincture of iodine. This treatment diminished the frequency and the offensiveness of the evacuations and relieved the pain, so that our attempt to carry out the first indication was, to a certain extent, successful. How, in the next place, were we to give effect to the second indication—viz., to combat the tuberculous infection? I had found in former cases of tuberculous peritonitis—or cases diagnosed as such—that had been under my care that recovery had in some instances appeared to follow the use of iodine or iodoform applied freely to the abdominal surface as well as given internally; therefore four days after this child's admission I ordered a mixture of equal parts of iodoform ointment and cod-liver oil to be rubbed in freely over the abdominal surface twice daily; and a week after admission the bismuth mixture was discontinued and a pill containing a quarter of a grain of iodoform and half a minim of creasote was given thrice daily. The patient at first made little or no notable progress, and it was not until about the middle of July—nearly four weeks from the date of her admission—that the motions had become normal, no longer offensive, and quite formed. The temperature also showed a marked improvement. She was therefore allowed some solid food in the shape of eggs, or custard, or fish; but with this change in the diet the diarrhœa returned and the motions became offensive and the temperature rose and again assumed the hectic type. We therefore had again to return to the liquid diet. On weighing the patient we found that during the time she had been in the hospital she had lost nearly 12 lb We, however, persevered with the treatment and by August 4th the motions had again improved in appearance and the temperature had fallen to normal. But this improvement was not steadily maintained, for by the middle of August the child's weight had diminished two pounds more and she had had another return of diarrhœa but not a severe one; it was noted at this date that the fluid had disappeared from the right pleural cavity and the chest conditions had become normal. There was now no complaint of abdominal tenderness nor any dulness in the flanks, but there was a trace of albumin in the urine which soon disappeared. About this date a slow and steady but unmistakeable improvement began to set in. On the 24th it was noted that for the first time since her admission she had gained a little in weight. She was then allowed a little solid food (bread in soup and bread-and-butter). Mr. J. C. Briscoe, the house physician, to whom I am indebted for these notes, observes that between August 25th and the 30th "there was a slight attempt at a return of the hectic temperature," but by Sept. 1st the temperature had become normal and had remained so. She had now

[2] Allbutt's System of Medicine, vol. iii., p. 658.
[3] Practice of Medicine, third edition, p. 286.
[4] Manuel de Pathologie Interne, vol. ii., p. 608, seventh edition.

been under treatment in the hospital for more than 10 weeks. On Sept. 7th it was noted that the improvement was maintained; her weight had improved from 4 st. 12 lb. to 5 st. 1 lb. and she was then put on ordinary diet. The bowels and the temperature were normal. During the next fortnight the improvement became very marked. On the 12th she was able to get up and recline on the couch, and on the 21st the local application of the mixture of cod-liver oil and iodoform ointment was discontinued having been kept up for three months. A teaspoonful of cod-liver oil was given three times a day. On the 30th her weight had increased to 6 st. 3½ lb. On Oct 8th the creasote and iodoform pills were discontinued and on the 15th the patient was discharged—so far as could be judged—cured. Her weight was then 6 st. 8 lb.

Now one important point in the treatment of this case is the persevering manner in which we applied our remedies. The local application of iodoform ointment and cod-liver oil was continued uninterruptedly from June 17th to Sept. 21st, more than three months, and the iodoform and creasote pills were given from June 21st to Oct. 8th. When, owing to the commencement of the vacation, I discontinued my visits to the hospital at the beginning of August, I was by no means sanguine as to the results of the treatment. There had been relapses from time to time and a return of some of the characteristic abdominal symptoms and the patient continued to lose flesh and to look very ill—notwithstanding that she had been six weeks under treatment. On July 29th it had been noted that the temperature had again risen and had again assumed the hectic type. The bowels also had again become loose and the motions offensive. Even on August 13th there was a relapse in the condition of the bowels, but only in a slight degree, and there was no notable rise of temperature. The weight, however, had fallen to 4 st. 12 lb.

I can imagine an impatient medical attendant becoming dissatisfied with the progress of the case and sceptical as to the ultimate value of the treatment. But there were one or two points that were distinctly encouraging. The fluid had disappeared from the right pleural cavity and there were no longer any abnormal signs about the chest. The abdominal swelling and tenderness were less and there had been an improvement in the temperature. Still, when I handed over the care of this case to my representative on my departure for my holiday, as I have already said, I was by no means sanguine as to the result. When I returned to the hospital in the beginning of October I was not a little gratified and perhaps somewhat surprised to have presented to me a bright-looking, well-nourished, active girl, with the appearance of perfect health and to be told that this was the same patient I had left two months before a wretchedly ill, emaciated, shrunken, and exhausted child. Instead of weighing as she did then 4 st. 12 lb. she now weighed 6 st. 8 lb.

A point of some interest in this case was the co-existence of pleurisy with effusion—no doubt of tuberculous nature. The frequency with which tuberculous pleurisy accompanies tuberculous peritonitis has been remarked upon by many authors, and especially by Dieulafoy and Osler, and its occurrence under these circumstances is easily explicable on account of the close lymphatic connexion between the two serous cavities.

I do not quite agree with those French pathologists and physicians who maintain that "probably the greater number of primary pleurisies are tuberculous," but I am more disposed to accept their teaching that "pleural tubercle is eminently curable, thus resembling the peritoneal form." My belief is that all primary pleurisies are either *tuberculous* or *rheumatic*, and that the rheumatic toxin, whatever that may be, is responsible for a goodly number, at any rate, in this country. And this belief is founded on bedside observation—on the fact that the symptoms of the pleurisies which I call rheumatic disappear rapidly on the administration of salicin or the salicylates. I agree, however, that pleural and peritoneal tubercle are "eminently curable"—indeed, this is the truth I am now concerned in enforcing, and before I have done I shall call your attention to a suggestion that meningeal tubercle may in course of time come to be included in the list. In the serous membranes it seems possible to encounter the tubercle bacillus unaccompanied by any other pathogenic organism and amenable, therefore, to simpler and more direct methods of treatment. In the lungs it is too frequently associated with other active pathogenic microbes, and therefore presents in advanced stages a far more complex and more difficult problem to the physician.

CASE 2.—The next case to which I wish to call your attention was a very interesting one, but as it occurred in private practice and as no special or continuous notes were taken you will not expect me to enter into any minute details. Soon after the occurrence of the case which I have just related to you I was summoned by an eminent surgeon to see with him a young lady upon whom he had a fortnight before performed an abdominal operation. The history he gave me was an interesting one. This patient had suffered for some time from abdominal pain and discomfort of an obscure nature. She had consulted one hospital surgeon who diagnosed the presence of a dermoid cyst and recommended its removal. Subsequently she was seen by the eminent surgeon who called me in and he diagnosed the existence of appendicitis and an operation was undertaken for its relief. When the surgeon opened the abdominal cavity he was astonished to find that the case was one of tuberculous peritonitis in a somewhat advanced stage. Not only was the peritoneum thickly studded with tubercles, but the walls of the intestines seemed also to be largely involved. He thought the prognosis under these circumstances was very unfavourable. A fortnight after the operation he called me in to the case, referred to the case I have already related to you, which had been mentioned to him, and asked me to take charge of his patient and to do the best I could for her. At that period there was no sign that any benefit had resulted from the operation but rather the contrary. The patient was very ill, very weak, and exhausted, with severe diarrhœa and a temperature ranging between 103° and 104° F. My first effort was by means of appropriate remedies to endeavour to control the diarrhœa which was serious and exhausting. This in the course of four or five days I succeeded in doing. I then began the iodoform applications to the surface of the abdomen, freely applied twice daily as in the preceding case. I also gave the patient iodoform and creasote in pills internally. She soon began to improve, the diarrhœa entirely ceased, and the temperature in a few weeks became normal. After five weeks of this treatment she was well enough to be removed to the seaside. She was kept under observation for a considerable time and she continued to improve with occasional drawbacks which I need not now enter into. She is at present quite restored to health.

There are two very interesting points in the history of this case deserving our consideration. 1. As to the difficulty in diagnosis. There had never been any suspicion in this case of the existence of tuberculous peritonitis until the operation revealed its presence. This has frequently happened before in similar cases. So latent is this disease in its onset in some instances and so obscure are its early symptoms that abdominal section, undertaken for quite other conditions, has often disclosed its existence; indeed, we may say that we were indebted to this circumstance originally for the suggestion that laparotomy might be a cure for certain cases of tuberculous peritonitis.[5] I may also mention that there was no family predisposition to tuberculous disease in this case; indeed, after the discovery of the nature of the malady an investigation that was made seemed to point to its originating in the consumption of milk from a tuberculous cow. 2. Another interesting question to consider is, Did the surgical operation promote the cure of this case? Indirectly it certainly did, for it led to the discovery of the tuberculosis, and had not this been discovered we can hardly doubt that the patient's life would have been imperilled. I have already told you the condition of the patient when she came under my care. But before I attempt to estimate the value of surgical operations in the treatment of tuberculous peritonitis I should like to mention very briefly my third case and then return to this point.

CASE 3.—A few weeks after the patient in the last case had become convalescent I received a telegram asking me to meet a medical man in the west of London. He explained to me that he was only acting as locum-tenent, that the case had been handed over to him by a professional neighbour who was away on his holiday (it was the middle of August). He said, as was true, that the case was a desperate one and that he had no hope of recovery. I am unable to give you a very precise or detailed

[5] In 1862 Sir Spencer Wells on opening the abdomen for ovariotomy found the case to be one of tuberculous peritonitis; the result of the error was that the patient was cured.

history of the case under these circumstances, but I understood that the child (it was an only daughter about 11 years of age) had been ill only a few weeks, that the illness had been more or less an acute one, and that the diagnosis of the case arrived at by his absent neighbour after consultation with a well-known physician, and from the symptoms observed, was perforation of the bowel. He further stated that he had himself had the advantage of consulting with a hospital surgeon as to the advisability of an operation, but the surgeon did not consider it advisable on account of the great prostration and unpromising aspect of the patient. The little patient was, indeed, extremely ill. She could retain no food whatever, either given by the stomach or by the rectum. Attempts to feed her by the rectum were followed always in a short time by the return of the food mixed with fæcal matter. The child was terribly emaciated and the abdomen was much distended and tympanitic. The pulse was small and rapid. I found on inquiry that she had been staying recently at the seaside and had been in the habit of drinking milk from a source which might have been infected, although nothing was certainly known nor had any suspicions on this head been aroused. After a careful examination of the case I pointed out to the medical man in attendance that there was nothing in the case inconsistent with the view that it might be one of tuberculous peritonitis of an acute form. There was a certain amount of bright intelligence about the child notwithstanding her wretched physical condition which seemed to me of somewhat favourable import. I gave some instructions in regard to the best methods of attempting to feed the child and I strongly advised the rubbing in of iodoform ointment to the abdominal surface and the administration by the mouth of pills of iodoform and creasote. These measures were most thoroughly carried out by the medical man and the skilful nurse in attendance. About a fortnight afterwards I received a letter from the medical man in attendance to the effect that the child had borne the treatment exceedingly well, had retained the pills, had no longer either diarrhœa or vomiting, was beginning to gain flesh, and, in short, that there was a "wonderful change." I saw the patient a day or two after this and the change was certainly very remarkable. The child was bright and cheerful; she was taking fluid food well and readily. The abdominal distension had greatly diminished and there was little or no pain on pressure. I happened to be leaving London for Scotland that same evening and I did not see this patient again, but I have been informed that she steadily improved and made a complete recovery.

I have thought a brief account of these three cases might be worthy of your attention, as they are not picked cases, but occurred in close succession within a few months of one another. The patients were all treated in the same way and they all made good recoveries. They were all desperately ill and of a disease which not so very long ago was regarded as a very fatal one.

There is one circumstance in connexion with the cases I have related to you which I am disposed to think is a very important one from the therapeutic point of view—that is, they were all more or less acute cases, two of them markedly so, and they were in young people between 10 and 20 years of age. I have certainly seen this method fail to produce any marked curative effect when applied in very chronic cases of the dry adhesive type and in older persons. And, as we shall presently see, these are also the cases in which the results of surgical operation are far less favourable than in ascitic cases in the early stage. Indeed, it is the old, old story that what is an efficient remedy for a disease in the early stages often fails to be so in the more advanced periods; and this is easy to comprehend. In these advanced chronic cases, and especially in patients of riper years, the conditions essential to the curative action of a remedial agent are probably absent. In such cases the facility of the diffusion of an antitoxic or anti-bacterial agent into the affected tissues may be very much less than in a patient of tender years and in attacks of recent origin. Variations in absorbability, variations in the resistance and reaction of tissues, variations in the antecedent conditions of the solids and fluids affected, must necessarily entail variations in the activities of remedies, but which are none the less remedies because their curative efficiency needs the presence of certain favourable conditions. This important truth is frequently overlooked and excellent and trustworthy remedies are occasionally discredited and discarded because they fail to cure under other conditions than those which determine their curative effect. This truth applies also to surgical methods and Professor Watson Cheyne[6] has observed: "The results of [surgical] treatment vary enormously in different cases."

The best results are obtained in the early stage and when there is always more or less ascitic fluid in the peritoneal cavity; in this stage there is "not necessarily any matting together of the intestines or shrinking or adhesion of the omentum and mesentery." But in advanced chronic cases you may find adhesions and fibroid induration of the omentum and mesentery—they become matted together, thickened, and shrunken. The intestines may also be bound together by new fibrous tissue, the tubercles also may be found coalesced into large masses undergoing caseation, and the mesenteric glands may be enlarged and caseous. When the disease has reached this stage the conditions are distinctly unfavourable both for surgical and medical treatment.

There is, however, this distinction between medical and surgical treatment—viz., that *medical* treatment cannot be begun too early, whereas *surgical* treatment may be. Professor Watson Cheyne[7] points out that it is an error to operate too soon, for if operation is done too early the disease is apt to return. He recommends that medical treatment should be given a reasonable time, which he estimates as from four to six weeks in the acute cases and from four to six months in the chronic ones. The operation he recommends is a very simple one; in cases with effusion without adhesions the abdomen should be opened in the middle line below the umbilicus and the fluid allowed to run out, aided by turning the patient on his side and "perhaps removing some of it by means of sponges," then stitching up the wound again. He does not recommend washing out the peritoneal cavity unless the effusion is purulent; in that case he advises the use of salt solution for this purpose and then introducing a little iodoform and glycerine emulsion into the cavity before closing it. He also urges that medical measures should be superadded to the surgical ones as soon as possible. Ebstein also supports Professor Watson Cheyne's opinion that "simple opening of the peritoneum" is best "without antiseptics and without washing out or drainage."

As to the cases in which operation should be performed authorities differ somewhat. Some writers draw a sharp distinction between cases of tuberculous peritonitis with ascites and the plastic form in which the peritoneal cavity is obliterated by adhesions, and they maintain that operative interference in the latter is "useless and worse than useless." Professor Watson Cheyne does not hold this view. He says: "All, even the gravest forms, show some good results, and there is *no* form in which we can say that laparotomy is absolutely useless." He states that he has "had success in the dry form as well as in the ascitic." He considers that the most favourable cases are those with *localised* ascites and the next those with *diffused* ascites. Then comes the fibro-adhesive form—when moderate in extent and no ascites. In cases where the abdomen contains large caseating masses successes are not frequent, but he maintains that they do sometimes occur. He does not consider the co-existence of early phthisis a counter-indication, but with advanced phthisis the results are not good. He is doubtful if laparotomy does any good in cases with intestinal ulceration. Then as to the proportion of cures in cases operated on. The same authority tells us that something like 75 per cent. are improved or cured by laparotomy, but he believes that if all cases were operated on, not merely selecting the most favourable ones, 50 per cent. would probably be the outside limit of improvement or cure. If, on the other hand, the more favourable cases only were treated by laparotomy the percentage of successes would be much higher. Second or third operations may succeed where the first fails and fluid re-accumulates. As to the *rationale* of the cure of tuberculous peritonitis by this simple surgical operation Professor Watson Cheyne admits that we are "absolutely in the dark." I think, however, his own suggestion is a reasonable one—viz., that after the removal of the fluid from the peritoneal cavity by incision, serum having anti-bacterial properties may be poured out and so the morbid process be arrested. For me the important fact is this, that apparently a *very slight change* in the environment of a pathogenic

[6] Harveian Lectures on the Treatment of Tuberculous Diseases in their Surgical Aspects, 1900.

[7] Ibid., p. 72.

organism is sufficient to arrest or nullify its activities and to lead to its disappearance.

I wish to put before you a somewhat more definite view as to how iodoform inunctions act in curing tuberculous peritonitis. When iodide of potassium is given by the stomach in a short time the presence of iodide can be detected in the saliva and in the urine. So when iodoform is rubbed into the skin of the abdomen in a young person it probably rapidly enters the blood and is, if regularly applied, continuously eliminated in the secretions, *including the secretions into the serous cavities*, and as these do not pass out of the body as the secretion of the kidneys does, they must, in course of time, become pretty richly charged with iodine compounds, at any rate sufficiently so to act as antitoxin to the tubercle toxin or as anti-bacterial to the bacilli. The first thing to be determined was whether the iodoform in the ointment when rubbed into the abdominal surface, was absorbed into the blood quickly and eliminated by the secreting organs such as the kidneys. Dr. Still has been so good as to make this observation for me at the Children's Hospital in Great Ormond-street. He found first, that iodoform ointment is excreted and easily recognisable in the urine as iodine or the salts of iodine; and, secondly, that the rate of excretion is very rapid. When half a drachm was applied to the abdomen it was recognisable in the urine four hours later, and apparently, after a second application, it reappeared in the urine in two hours' time. When only 15 grains were applied in another case it was recognisable in the urine 15½ hours after application. We have proof here of the rapidity with which iodoform is absorbed by the skin, enters the blood, and circulates as an iodine compound through the tissues of the body and is eliminated into the secretions.

Now, it is an interesting circumstance in this connexion that the idea that iodine is an antitoxin to tubercle has long been in the minds of physicians. I use the word "antitoxin" in a wide and general sense. I quoted in the beginning of this lecture Sir Thomas Watson's gloomy prognosis in cases of tuberculous peritonitis. I will now quote what he adds: "It has been thought that friction upon the abdomen with ointments containing iodine have done good, so that it will be well to make trial of such." Quite recently[8] two Italian physicians have recorded a case of tuberculous peritonitis in which a cure quickly followed the injection of a solution of iodine made by dissolving 15 grains of iodine and 30 grains of iodide of potassium in one and a half ounces of water. They injected first half a syringeful and then a syringeful in the genital region daily for 10 days and then on alternate days. After about a fortnight some of the fluid was withdrawn from the peritoneal cavity and examined bacteriologically, culture preparations were made, and guinea-pigs were experimented on, but no tubercle was found. After 10 weeks of treatment the patient was discharged cured.

While thinking over these cases I called to mind having read of a Swedish physician, Dr. Emil Nilsson, who reported that he had cured one undoubted case of tuberculous meningitis by rubbing into the shaved scalp an ointment of iodoform (1 in 10), and I found the following amongst my notes. The patient was a boy, eight years old, four of whose brothers and sisters had died from tuberculous meningitis and whose mother's family were phthisical. The symptoms were headache, torpor, convulsions, strabismus, and pyrexia. After other ineffectual treatment, the child becoming steadily worse, the head was shaved and iodoform ointment was rubbed in and an oilskin cap was put on. *This was done three or four times a day.* Improvement soon followed this treatment and consciousness was restored. There were, however, severe coryza, redness of the lips, and an irritable cough, the breath smelling strongly of iodoform. The ointment was discontinued and syrup of the iodide of iron was given. The unpleasant symptoms rapidly disappeared and the child was soon running about in good health.

In THE LANCET of Jan. 16th, 1897, p. 159, there appeared a paper by Professor Thoma of Geneva advocating the treatment of tuberculous peritonitis by creasote given in enemata. He gave at first five minims, increased afterwards to 15 minims, in four ounces of emulsified cod-liver oil, once daily. He continued this for some weeks and then interrupted the treatment for five or six days. He obtained good results. He remarks that "laparotomy is no doubt the best and quickest of all methods for dealing with these cases in which the peritoneum is covered with miliary tubercles, but," he very sensibly adds: "It is always a serious operation and one also which not every practitioner is competent to perform, and moreover parents often object, and physicians would gladly welcome other methods." The method which I followed in the three cases I have related to you of the outward application of iodoform ointment and the internal administration, three times a day, of small doses of iodoform and creasote, is, I think, more promising than surgical operations in those cases in which there is evidence of intestinal ulceration. The disease is thus attacked on both sides—the peritoneal and the intestinal—by anti-bacterial agents.

In conclusion, I would suggest that we should bear in mind that "antitoxins" are not limited to animal products and that we should not neglect the study of those which may be found in the mineral and vegetable world. We must not be led away by fashion and popularity to neglect every kind of remedial agent that is not a "serum" or an animal extract. The oldest and surest antitoxins we possess are mercury and quinine—one from the mineral, the other from the vegetable world. Their effects are better known, are more certain, and are more reliable than those of any other antitoxin at present known to us. That many animal extracts and animal fluids should possess active therapeutic properties, as many vegetable extracts do, was only to be expected. Let us by all means study their effects and learn the extent and the limitations of their uses; but do not let us neglect the study of other curative agents or consider them less important and less interesting because they are not derived from animal sources.

SOME PERSONAL EXPERIENCES OF THE EPIDEMIC OF ENTERIC FEVER AMONG THE TROOPS IN SOUTH AFRICA, IN THE ORANGE RIVER COLONY.[1]

BY H. H. TOOTH, M.D. CANTAB., F.R.C.P. LOND.

IT has been my privilege to be actively engaged in one of the most extensive and serious epidemics of enteric fever of modern times. Any value that the following recollections and reflections may possess must be attributed rather to their being the outcome of personal observation on the spot than to any particular qualification on the part of the observer other than may be claimed by a general hospital physician. I must thank the council of the Clinical Society of London most heartily for having done me the honour to ask me to open this discussion.

I wish to speak about myself as little as possible, but I cannot refrain from taking this opportunity of recording the extreme cordiality and courtesy with which I was received wherever I was sent by all ranks of the Royal Army Medical Corps, from the Surgeon-General downwards, and I cannot but believe that the intercourse, social and professional, that was established between the military and civil branches of our profession in the ups and downs of the great campaign may help to lessen the distance which has insensibly grown between them, to the detriment of the service on the one hand and to our loss on the other.

I propose to limit my remarks this evening to a discussion of the outbreak of enteric fever on the Orange River Colony side of the campaign, from the following points of view: (1) the origin of the epidemic; (2) the dissemination of the disease; (3) the general precautions taken to limit the spread of the disease; (4) preventive inoculation; and (5) some remarks on treatment in hospital.

THE ORIGIN OF THE EPIDEMIC.

It is, as may be expected, very difficult to assign a definite date for the first appearance of this insidious disease. But it was in the Modder river camp that we must look for the first cases, and I was given every facility by the colonel and officers of the Guards' Brigade Field Hospital, with whom I

[1] Being the opening paper of a discussion upon the Recent Epidemic of Typhoid Fever among the Troops in South Africa, read before the Clinical Society of London on March 8th, 1901.

was staying in February, 1900, for obtaining information on this point, and though unfortunately I did not compare the facts so obtained with the experience of the other field hospitals, yet I think that we may take the experience of the Guards as being probably typical of that of the whole force. From the admission and discharge book of the Guards' Hospital we find that enteric fever made its first appearance about Dec. 23rd. Four men of the same company, known to be friends, reported sick at about the same time and therefore they may be assumed to have been infected at somewhere about the same date. Up to this time dysentery was the predominant feature of the daily record of admissions, but after this date enteric fever almost replaced it. It must be remembered that the Guards arrived in South Africa in the latter part of November, 1899, and they proceeded after disembarkation straight up to Orange river station, where they halted for two or three days. The battle of Belmont was fought on Nov. 23rd, that of Enslin on the 25th, that of Modder river on the 28th, and that of Magersfontein on Dec. 11th. The Guards were in all these engagements. The long wait of the troops at the Modder began on Dec. 12th.

Now, of course, the date of infection of the first cases of enteric fever above alluded to must be entirely a matter of speculation. But putting the incubation period at the outside at three weeks we are forced to the conclusion that the enteric infection took place in the vicinity of Modder river. That the disease could have been imported from England or even from the Cape seems highly improbable. Modder river cannot be said to be a town or even a village. It consists of the station, a small hotel which was the headquarters of the staff, a store, and a schoolhouse, all near the station. There were several small farmhouses and two or three little hotels, mostly on the banks of the two rivers. The Modder and the Riet rivers join to form one river which retains the name of the Riet, and near this junction the railway crosses the Riet by a fine viaduct which was wrecked by the Boers. The two rivers are picturesque, with well-wooded banks, and serve in times of peace as a pleasure resort for the people of Kimberley.

Kimberley is regularly visited by enteric fever and it is therefore possible that the soil about Modder river station may have become contaminated. Jacobsdal is on the Riet about 10 miles above the camp, and it was known that there were cases of enteric fever there. There is therefore every possibility that men might have been infected by drinking the water of the Riet; but the main source of water-supply was the Modder, and there was no known contamination of it at this time in its course above.

As we shall see later, though it is impossible to acquit the water-supply of having a share in the origin, yet in all probability other agencies played a still more important rôle in the spread of the disease. It is important to bear in mind that this outbreak at Modder river was probably the direct antecedent cause of the great epidemic at Bloemfontein, and that the troops who entered Bloemfontein were deeply tainted with the disease.

The principal medical officer, Colonel Townsend, kindly allowed me to see the daily returns of enteric fever cases from Jan. 29th to Feb. 6th, 1900, and though I think that they understate the true state of the case, yet they give some idea of the rate at which the disease progressed in the early days. Up to Jan. 29th 97 cases had been reported and 17 deaths. On Feb. 6th the total had reached 156 cases and 27 deaths. These figures seem small, but they are fairly evenly distributed over the whole camp, indicating a widespread incidence. The general advance began about Feb. 11th, Kimberley being relieved on the 15th. Jacobsdal was occupied on Feb. 16th, and the next day Paardeberg was surrounded. 10 days were spent around Paardeberg which surrendered on the 27th. Bloemfontein was occupied on March 13th, about a month after the move from Modder river. The possibilities of infection on this long march, especially during the investment of Cronje's laager, must have been very considerable, but the fact of the widespread infection of the forces at Modder river must not be lost sight of, and there can be no doubt that men were falling out sick with the disease every day from the first day of the advance. The Bloemfontein epidemic should be regarded as the direct continuation of that begun at Modder river.

DISSEMINATION OF THE DISEASE.

An army consists largely of individuals of the age most vulnerable to enteric infection. It would be impossible to find a more suitable medium for the growth and dissemination of the bacilli than an army of 40,000 young men of ages between 19 and 25 years. Given therefore a preliminary case or two and from quite small beginnings indefinitely large and serious results may follow. We will now discuss at some length the various agencies by means of which this scourge may be spread over a camp, or by communication by man to man.

Water.—Here, as in England, the water-supply deserves our first attention. The water-supply of the camp at Modder river station included the Modder, the Riet, and certain wells. The river water was charged with thick yellow mud, which was so fine that it seemed never to settle and which rapidly clogged any filter. As will be explained further, the authorities used various means for purifying the water and even caused wells to be sunk, but all these efforts were rendered futile by the action of the soldiers themselves who appeared to prefer the untreated river water. One never passed the drift without seeing the men drinking from the river and filling their bottles. If, therefore, there was any enteric contamination of either of the rivers above, the water-supply must be held to have had a considerable share in the propagation of the disease. The soldiers were also bathing all day in the Modder, but below the point at which the water was drawn for drinking purposes. No doubt many men with the disease on them would be bathing at times and might thus infect their comrades. There was a well at the Station Hotel from which the Headquarter staff was supplied. This water looked clear and sparkling, but the chemical examination of it was less favourable than even of that of the Modder river itself.

At Bloemfontein the question of water-supply was a very pressing one and on my arrival there I was asked to serve on a board to inquire into the water-supply and drainage of the camps. It will be remembered that the waterworks at this time were in the hands of the enemy, so we had to rely entirely upon local sources of supply. These consisted of wells and the spring from which the city takes its name. The spring is situated to the south-west of, and close to, the town. It consists of a brick-lined reservoir of about 10 feet square covered in by a small red brick building, evidently an old engine-house. This all lies in a dip in the ground, and is inclosed by a paling. The veldt on this side of the city drains into two large natural ditches or dongas which receive in their course numbers of smaller ones. These two dongas meet not far from the spring to form one large watercourse which runs through the town. In ordinary circumstances this is dry, but in the rains it and its tributary dongas become rushing torrents, as we had ample opportunity of seeing for ourselves. On the banks of these dongas were several camps; for instance, not 400 yards away was a field hospital in which were 60 enteric fever cases and provided with open trench latrines. Moreover, a donga is a convenient dumping ground for all sorts of refuse. There was no evidence or suspicion that there was any communication between the spring and the donga which were at least 30 yards apart, but the field hospital above alluded to was ordered to be removed. Another action of this board was to cause the provision of bucket latrines to all hospitals and other camps; this was a very important and salutary measure. The water of the spring looked good, but by chemical analysis I found that it contained a suspiciously high percentage of absorbed oxygen and a trace of nitrites. In addition to the spring the city and forces had to rely on wells of which there were several. I have personal knowledge, however, only of those near our own camp, and these were of the tube variety sunk through over 100 feet of underlying rock. These wells gave a good supply of excellent water and from the manner of their construction they were free from any possibility of surface contamination. There were two of them at first and the engineers soon sank another. But these were not sufficient for the needs of the whole camp and so the spring continued to be used as well.

The water-supply from the Modder reservoir was re-opened in May when the epidemic was moderating and therefore can scarcely be looked upon as a factor of influence in itself either way. However, I made several chemical examinations of this water and found it very unsatisfactory, containing a large percentage of absorbed oxygen. Thinking that it might be contaminated in its course through the mains, especially after a long period of stagnation, I procured water direct from the reservoir and found it still far

from satisfactory. It is, however, quite probable that the contamination was of a harmless vegetable nature. All these chemical analyses are open to the objection that they give no hint as to the real nature of the organic material. They should be regarded as danger signals only; a personal examination of the source and course of transmission is of much more value, but unfortunately it is often impossible. It is quite obvious that a harmless water may give a very unsatisfactory analysis, while an apparently pure sample may contain many bacilli. Bacterial examinations can scarcely be expected under the circumstances, even if they were of much value.

The results of atmospheric disturbances.—A visitor to the camp at Modder river would not have to wait long to see a sandstorm, and one would be quite enough to satisfy any curiosity which he might have had. The veldt, generally speaking, is a plain of sand in so fine a state of division as to deserve the name of dust. After the rains there is a certain amount of loose vegetation which binds the sand, and rain and sun also harden the surface which is not, under ordinary circumstances, much affected by the wind; but by the incessant movement of horses, men, and vehicles the surface becomes so ploughed up that one might walk a mile or more ankle deep in soft reddish-yellow dust. From time to time a gale would spring up, and in a short time the whole camp would, on the brightest day, be buried in the darkness of a London fog, and sand and dust would cover everything and everybody. On still days even it was rare not to be visited by a number of small whirlwinds, called "sand-devils," which would pass slowly along sucking up quantities of sand and any light articles such as pieces of paper, carrying them to an astonishing height in the air and depositing them broadcast. The result of all this was that sand entered largely into every article of food, for the cooking was performed in the open air. The air at that time was intensely dry, so that it is not too much to suppose that all sorts of fæcal and urinary contamination must have been disseminated with the sand and dust. The same state of things obtained at Bloemfontein but in a minor degree, because the atmospheric conditions were generally quieter at that time of the year.

As a factor, then, in the spread of enteric fever we must by no means overlook sandstorms, which are everyday phenomena in many parts of the world where the British army may be sent, and it is quite a question whether they have not been more important factors in this war than the water itself. For that the water contained enteric fever bacilli is a matter of speculation, but that enteric stools and urine must have been deposited in the latrines and other places by men in the early stages of the disease there can be no reasonable doubt.

Flies.—As may be expected the conditions in these large camps were particularly favourable to the growth and multiplication of flies which soon became a terrible pest. I was told by a resident at Bloemfontein that these insects were by no means a serious plague in ordinary times, but that they came with the army. It would be more correct to say that the normal number of flies was increased owing to the large quantities of refuse, dead horses, &c., upon which they could feed and multiply. They naturally infest persons who are ill but seem to be peculiarly attracted to enteric fever patients, hanging in loathsome groups around their mouths and feeding-vessels. They were all over our food and the roofs of our tents were at times black with them. It is not unreasonable to look upon flies as a very possible agency in spreading the disease not only abroad but at home. Most of the temperature charts that had hung over the patients' beds were plentifully spotted with the excreta of flies and on my return home Dr. Schölberg was so kind as to make cultivations from them; but though he obtained cultures of many organisms he did not isolate the enteric fever bacillus, which circumstance, however, as he says, is not a matter for surprise considering the age of the material (three months at least).

It is a well-known fact that with the first appearance of the frost enteric fever almost rapidly disappears. The winter in South Africa is very mild compared with that which we are accustomed to in England. It is true that the nights are cold, sometimes to many degrees of frost. But the days are warm and bright; for instance, in my tent at midday the temperature was rarely below 70° F. and sometimes as high as 80°—in fact, about the temperature of an English summer day. It seems hardly credible that the almost sudden cessation of an epidemic can be due to the effect of cold upon the enteric fever bacilli only. But there can be no doubt in the mind of anybody who has been living on the open veldt as we have for three or four months that the flies are extremely sensitive to the change of temperature and that the cold nights kill them off rapidly. On consideration of these points it is surely justifiable to assign an important share to flies in the spreading of infection.

Personal infection from man to man.—Even in the best ordered London hospital it is unfortunately not uncommon to see enteric fever pass from patient to nurse and so to other patients. On consideration of the mode of life of the soldier on active service one is struck by the facilities which it offers for infection. Personal cleanliness is often an impossibility even for officers, much less for privates. There is barely enough water for drinking, let alone for washing purposes. The men slept 15 in a tent—when there were tents—and that fact presented considerable possibilities for infection. Far be it from me to say that the soldier is naturally dirty, but there can be no doubt that he has no idea of hygienic matters. This is shown forcibly by our experience at Bloemfontein. We had a large number of officers down with enteric fever, and as the nursing was at that time very heavy we were glad to avail ourselves of the help of the personal servants of these officers. They had not much to do, of course, with the direct nursing of their masters, but nevertheless a large number of them contracted the disease while with us. Of course some of them may have been infected at the same time as their masters. On the other hand, of our own orderlies, eight only took the disease in the whole seven months, though they were in constant attendance on bad cases. This may be due to protective inoculation, but it is also probably owing to their being alive to the ordinary precautions necessary. Bearing in mind the insidious mode of onset of enteric fever it is obvious that at any one time there must have been in these large camps, many men still at duty, with the disease on them, and therefore capable of giving it to their comrades in the close intercourse of camp life.

In conclusion of this part of my subject I cannot help remarking that, far from its being a matter of surprise that the epidemic was so severe, it seems to me, who have lived through it, a matter of congratulation that it was not more so, considering how many unavoidable causes were at work.

The probable effects of diseases antecedent to infection.—Here seems to be the place to discuss shortly certain points of more than academic interest, but for which clinical data are at present, so far as I know, lacking. It is known, experimentally, that the virulence of the bacillus becomes much increased by the presence in the blood of the toxins of other organisms, even of such as are found normally in the alimentary canal—as bacillus coli, for instance.[2] That is to say, an injection of a culture of enteric fever bacilli of slight, non-lethal virulence, may become greatly increased in virulence after the intra-peritoneal injection of streptococcus toxin. I quote from Dr. Horton-Smith's lecture[3]: "Sanarelli showed ..... that all that is necessary is to inject into a guinea-pig at first a dose not quite sufficient to be fatal. The animal recovers, but for some time afterwards attenuated typhoid bacilli may be found in the purulent focus at the seat of inoculation. If now, in this condition a dose of toxins either of bacillus coli or of bacillus proteus vulgaris be injected into the peritoneum the typhoid bacilli at once acquire fresh virulence, the organism is invaded afresh, and the animal dies from acute experimental typhoid fever. More important still, on two occasions he was able to determine such a relapse by injecting small quantities of the toxin into the stomach and so into the intestines, thus exactly reproducing the conditions occurring in the human subject." Here we have an important principle enunciated from the laboratory, but which opens up a field of speculation perhaps not altogether profitless. It is conceivable, nay, more than probable, that every man in these great camps, ourselves among the number, may have at times received into the alimentary canal enteric fever bacilli which may have grown and multiplied but without producing the characteristic disease. If this be so we may assume the existence of an immunity such as a previous attack might establish, or, as it is hoped, inoculation may imitate, or a natural immunity that we wonder at but cannot explain. It may be

[2] Horton-Smith: Goulstonian Lectures, 1900, in which this question is fully discussed, with many references.

[3] Op. cit., p. 35.

that such bacilli never get through into the circulation, but are passed away harmless. It is almost allowable to go a step further in speculation and to admit the possibility of the bacilli actually circulating in the blood without causing the disease. This is not so chimerical an idea as may appear at first sight, for it is now well known that persons who have had the disease may retain bacilli in their tissues for indefinite periods, years even, without harm to themselves.

But suppose, in the light of laboratory experience, some other toxin to come on the scene, then the bacilli acquire a new virulence and the disease may assert itself. Such a starting-point might be supplied by a simple attack of gastro-enteritis with the multiplication of bacilli normally existing in the intestines in small numbers. I need scarcely enlarge upon the possibilities of such a trouble among soldiers with bad teeth and improper food. The enteric fever epidemic has so overshadowed, in the public mind, all other medical ailments that we are apt to overlook the fact that dysentery or its milder forms included under the head of diarrhœa was quite as prevalent among the troops as enteric fever was. It would be quite difficult to find a man who had not had diarrhœa for some time, longer or shorter, during his stay in South Africa. We were struck by the fact that in many of our cases the onset of the enteric fever appeared in the course of dysentery. I strongly suspect that the two diseases may exist in the same patient and that such a conjunction is of very unfavourable omen. A widely distributed, almost universal, dysenteric diarrhœa, a daily exposure to infection by enteric bacilli, here are the elements necessary for a severe epidemic of enteric fever. Mark the importance of such a generalisation if true. Diarrhœa and dysentery in themselves proved as a rule fairly amenable to comparatively simple treatment, but in the light of the foregoing remarks the slightest diarrhœa becomes invested with a new importance and officers and men should be warned to apply for immediate treatment at a time when the simplest measures may have the greatest effect. This warning is sufficiently warranted by consideration of dysentery on its own merits, but it becomes doubly so if we look upon it as a co-worker for evil with enteric fever.

PRECAUTIONS TAKEN BY THE AUTHORITIES TO PREVENT THE SPREAD OF INFECTION.

At Modder river some of the regiments—the Guards for instance—made efforts in the direction of purifying the water. One tried boiling and clarifying with a small quantity of alum. Another used filters (Berkefeld), having as many as seven large ones going all day, but the water was so thick that the cylinders became clogged every 10 minutes by a thick coat of slime. The Guards' Hospital made use of Pasteur filters. After filtration the water was most palatable, but the objection to the boiling process is that in a tropical climate the water takes so long to cool and when cooled forms a very flat beverage. At any rate, the men preferred the river water in its natural state, and unless sentries were posted along the banks of the two rivers it is difficult to see how they could be prevented from drinking from them even if it were positively known that the water was polluted. Five or six wells were sunk along the bank of the Modder river, but they did not seem to come into general use. The latrines were of the open trench variety, carefully inspected daily, and with sentries over them to see that they were used properly. They were continually being filled in and fresh ones dug. The water-supply at Bloemfontein has already been discussed and the important measure of substituting the bucket for the open trench latrines has been mentioned. In our hospital and No. 3 General Hospital at the base, it was the custom to disinfect enteric fever and dysenteric stools with mercuric perchloride solution (1 in 250), to remove them to a shed set apart for the purpose, and there to mix them with sawdust for burning. At Bloemfontein the stools were buried after disinfection. On the whole it is difficult to see what more could have been done. It is easy to make suggestions, but after all the carrying of them out will ever be subservient to the exigencies of warfare.

PREVENTIVE INOCULATION.

The conditions of life of an army on active service, even in camp, may well fill the soul of the sanitarian with despair. It is therefore with hope that we turn to the question of the possible artificial immunity by inoculation which has naturally evoked so much interest in this war. The figures that I have to give on this question are small, but they possess the value of personal observation. The Portland Hospital went out with the usual *personnel* of a Base hospital for 100 patients as shown in the table.

TABLE I.—*Portland Hospital.*

—	Inoculated.	Not inoculated.	Enteric fever.	Died.
Medical staff (five)	4	1	0	0
Sisters (four)	0	4	1	0
Non-commissioned officers, orderlies, and servants (32) ...	24	8	9	1
Total strength (41)	28	13	10	1

Of the non-commissioned officers, orderlies, and servants 24 were inoculated by us on the voyage out, and four of the medical staff at the same time. All of these showed the local symptoms at the time—that is, pain, stiffness, and local erythema; 17 also presented well-marked constitutional symptoms, general feeling of illness, fever, and headache. Nine of the orderlies contracted enteric fever. It is significant that two of these had the disease very severely, and one of them died; both of these had refused inoculation. Of the inoculated cases five had the disease lightly and two rather severely. One of the sisters also had the disease rather badly and she had not been inoculated.

Figures relating to patients admitted to the Portland Hospital.—Including the members of our own *personnel* above mentioned we had under treatment at the Portland Hospital 232 cases of enteric fever, most of which came under our care while the hospital was at Bloemfontein. These were cases under our personal care and do not include among them convalescents who were entered in the admission and discharge book as patients, but who really only occupied beds for a short time until a train could take them to the base. If these latter were reckoned the percentages would of course be lower. The following table shows the numbers and mortality among inoculated and non-inoculated (the sister is entered as an officer).

TABLE II.—*Portland Hospital.*

Enteric fever.	Recovered.		Died.	
	Inoculated.	Not inoculated.	Inoculated.	Not inoculated.
Officers (34)	21	12	0	1 = 7·6%
Non-commissioned officers and men (198)	29	141	4 = 12·1%	24 = 14·6%
Total (232) ...	50	153	4 = 7·4%	25 = 14·0%

Of the total number 54 had been inoculated at home or on the voyage out. Of these four died, making a percentage of deaths among the inoculated of only 7·4 per cent. 178 had not been inoculated, and of these 25 died, a mortality of those not inoculated of 14 per cent. The general mortality from enteric fever with us was 29 deaths out of 232 cases, that is 12·5 per cent.

If we take the experience among the officers alone, the evidence in favour of inoculation is still more striking. The officers as a body have presented themselves for inoculation in much larger numbers relatively than the men. This idea is expressed in our figures, but of course they must be taken as suggestions only. Of 198 non-commissioned officers and men 33 only had been inoculated—that is, 16·2 per cent.; but of 34 officers (including the sister) 21 had been inoculated, or 61·7 per cent.; only one died, and he had not been inoculated. It is scarcely surprising, in view of these figures, that my colleagues and I feel favourably disposed towards inoculation. I saw myself many bad cases among officers and men, not in our own hospital, and I am aware that several have died who had been inoculated, but this does not alter the strong general impression, gained by clinical observation, that the disease takes a milder and more benignant course in the inoculated than it does in the non-inoculated.

General remarks on inoculation.—A few remarks on the general question of inoculation may not be out of place here. The material used is a sterilised pure culture of enteric fever bacilli in broth. The broth contains, therefore, dead bacilli and a toxin, which toxin, however, seems to be inseparable from the bodies of the dead bacilli, for a filtered broth possessed little toxic power. The supply we took out was given to us by Professor Wright and was prepared in his laboratory at Netley Hospital. The dose is regulated by the quantity necessary to kill a guinea-pig of a certain body-weight. This is generally about 10 centigrammes or from 15 to 18 minims. It is therefore a virulent poison. Injected in the body more or less severe local and constitutional symptoms ensue. The local symptoms consist of pain at the seat of puncture (most often the loin), erythema, and lymphangitis spreading from the wound. The constitutional symptoms may include rigors, fever, headache, a feeling of more or less severe illness, and often a tendency to faint, all lasting for from 12 to 24 hours. These symptoms vary very much in different individuals. In some there is merely a transient indisposition and a pain in the side; in others there may be high fever, a temperature of 103° F. or more, and all the appearance and sensation of serious illness. After inoculation, for an indefinite period, the blood may give the Widal serum reaction; in my own case it was present three months after, well marked, and was made out faintly 13 months after. The inoculated person is now supposed to be in a state comparable to that of one who has lately had enteric fever; that is, he has had artificially thrown into his circulation the same toxin which is produced in enteric fever and which possibly influences the activity and growth of the bacilli. He is also assumed to possess, as a result, a certain degree of immunity such as is believed to be acquired by the individual after an attack of the disease. The liability to infection by enteric fever is so variable that we are justified in supposing the existence of an equally varying degree of natural immunity in different persons. Moreover, the toxic saturation point, so to speak, is also a variable one, as is exemplified by the tendency to re-infection or relapse so often seen clinically. I am inclined to think that when the reaction to inoculation is slight it is probably because the person possesses a certain degree of natural immunity, while, on the other hand, a severe reaction indicates proportionate vulnerability to infection. In the former case if the inoculated person take the disease he has it lightly, but in the latter severely. If this be true the toxin reaction possesses a real value as a means of forecast. But again, if this reaction is any measure of the degree of immunity possessed by the individual, it is obvious that after a pronounced reaction one or more re-inoculations should be insisted upon. For all that is claimed for the process is a temporary immunity, and that often partial only. An attack of enteric fever itself does not do much more, for second attacks are far from uncommon.

Inoculation has not yet had a fair trial. Medical officers have been too uncertain as to its value to insist upon one injection even, let alone re-inoculations. It is to be hoped that the figures of the whole army, yet to be published, will indicate with some certainty its value in the direction of lowering the mortality, as those quoted in this paper appear to do; this will justify the medical profession in taking a more decided attitude on the question than it has at present been able to take.

REMARKS ON TREATMENT.

It may seem almost an impertinence on my part in this presence to make suggestions on treatment, but my doing so may serve as a protest against the attitude in the present day of some of the profession as well as the public in assuming that the care of enteric fever devolves upon the nurse rather than the physician. I have no hesitation in saying that in a disease in which danger threatens from so many points watchful supervision by the physician and prompt treatment of symptoms are not only productive of comfort to the patient, but are also contributory in a high degree to a successful issue. I am of opinion that there may be many worse places in which to undertake the treatment of enteric fever than a comfortable tent in the open air; in fact, there can be no doubt that a tent is superior to a great many buildings, and this should be borne in mind in view of newspaper criticisms on the failure by the medical authorities to secure all the available buildings in Bloemfontein.

Diet.—One of our earliest difficulties at Bloemfontein was the scarcity of fresh milk. It becomes necessary in such circumstances to fall back upon preserved or condensed milk. There are one or two forms of sterilised milk which are as good and palatable as the fresh article, but they are expensive. The condensed milks of numerous brands are excellent for ordinary use, but it is doubtful whether they possess much nourishing power in illness. The common sweetened form is most unsuitable; patients had as a rule an intense objection to it and it caused undoubtedly in some cases troublesome vomiting. The other forms of nourishment—e.g., arrow-root, beef-tea, &c.—we had in plenty. Our principle in dieting was to use all forms of nourishment liberally when, in our opinion, it could be safely done. Most of our patients were thin and ill-nourished before contracting the disease.

For myself I have for many years held the opinion that food may be used much more boldly in enteric fever than is the usual practice. The safety of its employment depends solely on the digestive power of the stomach. If that power is normal, as in many cases it is, meat, for instance, is not likely to reach the ulcerated small intestine in a form more dangerous than a glass of milk is. For milk naturally becomes a mass of curds in the stomach before peptic digestion takes place, and if this latter process is incomplete the undigested curds may be a real source of danger. It seems to me that one should be guided in this matter by the state of the tongue, the evacuations, and the appetite of the patient. If the tongue is moist and fairly clean, if there is no diarrhœa—that is, if the evacuations are no more in number than, say, two a day and fairly consistent—and if there be no tympanites, and the patient has a strong craving for food, it is probable that his digestion will be good and that a liberal diet, including, for instance, finely minced meat, and even thin bread-and-butter, will not only be safe but beneficial. On the other hand, the dry brown tongue, frequent curdy stools, and especially if there be tympanites and a disinclination for food, indicate a condition of stomach that makes careful dieting imperative. Frequent small feeds of milk, peptonised or diluted with barley-water, Benger's food, &c., must be used with care and the stools frequently inspected as a guide to the state in which the food reaches the intestines.

But the mechanical effects of undigested food in the small intestines are not the only ones to be feared. Experiment seems to show that the growth of the enteric fever bacilli is favoured and their virulence enhanced by the presence in the intestines of other bacteria, such as are encouraged by the presence of undigested food, and themselves tending to produce gastro-enteric trouble. So that a slight gastro-enteritis may have a grave effect on the course of the attack. This has been justly emphasised by Dr. Horton-Smith in his Goulstonian Lectures (1900).

Alcohol we used most sparingly and only in the severer cases in which we feared heart failure, not at all in the milder cases. The small rapid pulse we considered the best indication for its use, not high temperature. We rarely gave more than three or four ounces and never more than six ounces in the 24 hours. The long-enforced abstinence of the soldier from all forms of stimulant renders him rather susceptible to its influence as a drug.

Digitalis and strychnine were of the greatest value. In one or two cases gradually increasing doses of the officinal liquor strychninæ were injected hypodermically to the extent of 30 minims in the 24 hours.

Headache.—This was one of the first symptoms that called for treatment, and from five to 10 grains of phenacetin generally gave speedy relief, or, failing this, a somewhat larger dose of antipyrin. In not a few cases this caused during the sleep that followed a profuse perspiration with perhaps a slight fall in the temperature. Beyond the discomfort of this no ill result followed. In some cases, however, this sweating was so annoying that it became necessary to add from one-hundredth to one-fiftieth of a grain of atropin, which usually stopped it.

Insomnia.—One of the most troublesome symptoms was insomnia and the cry for hypnotics was a very common one. As a rule, all that was necessary was a small dose of phenacetin, which proved as useful for this purpose as it did for headache. To patients who were delirious and constantly attempting to get out of bed we did not hesitate to give hypodermic injections of morphine and in considerable doses, such as a quarter of a grain, repeated several times if necessary.

Mouth and tongue.—The care of the mouth and tongue

may appear a minor detail. It is not so in the estimation of the patient, and in the severer cases the dry, black, and cracked tongue and lips are more than a discomfort—the pain of taking food may positively prejudice the nutrition of the patient. Local treatment may be all that is necessary—mechanical cleansing or the use of mouth-washes, and of these we found one containing potassium chlorate, glycerine, and iron perchloride the most useful. A mixture containing potassium chlorate and sodium bicarbonate given three times a day had a remarkable effect in cleaning and moistening the mouth and tongue, so much so that its use became almost a matter of routine.

Intestinal symptoms.—Diarrhœa is, I believe, less a symptom than a complication and as such requires treatment. In the minds of some it is regarded as an effort of nature to remove deleterious matter. I cannot accept this view, for in all epidemics a considerable, if not a large, percentage of cases have no diarrhœa, and these are, as a rule, favourable cases, whilst among the worst cases diarrhœa is most common. This is shown by the fact that in our 29 fatal cases 21 of the patients had more or less severe diarrhœa. Diarrhœa may be due to general enteritis consequent on extension of inflammation from the ulcerated patches to the general mucous surface of the intestine, but it is probably more often caused by an ulceration of the large intestine. There is no doubt that such ulceration is often found post mortem in the colon, very commonly in the region of the cæcum, and in two or three of our necropsies there was found extensive discrete ulceration of the large intestine even to the rectum. The treatment of this diarrhœa was comparatively simple and undoubtedly of great benefit to the patient. Bismuth carbonate or salicylate and chlorodyne proved the most useful drugs, supplemented if necessary by suppositories of one quarter of a grain of morphine. In obstinate cases enemas of 10 per cent. boric acid solution often gave permanent relief, a further hint that the cause of this symptom was in the large intestine. Tympanites, always a dangerous condition, rarely gave us any trouble; it is best treated by boric injection. A small injection of about four ounces of water containing two grains of quinine and half an ounce of brandy would often cause the patient to pass flatus with great relief. Hæmorrhage occurred in 10 cases, on the average at about the eighteenth day. In some it was very severe and was repeated two or three times and was so profuse as to cause blanching. It was almost invariably accompanied by a sudden fall of temperature and invariably by a rise in the pulse-rate. In only one was it found after death, not having been suspected during life, with which exception it never proved fatal, and though four of these patients died ultimately no blood was found in the alimentary tract. Hæmorrhage always yielded to, or after, treatment, which consisted of a mixture containing oil of turpentine and tincture of hamamelis of each half a drachm, and tincture of digitalis three minims. This was given every two hours, or alternately every hour with a drachm of hazeline. One of us used hazeline alone—a drachm every hour—with apparently equally good results. At the same time morphine suppositories were administered. Under this treatment the stools rapidly ceased to contain bright blood, and in about 12 hours were free from blood altogether. Perforation occurred in five of our patients, averaging at about the thirty-fifth day. The earliest day of occurrence was the nineteenth and the latest the fifty-first day of the disease. The prognosis of this terrible accident is gloomy in the extreme, whether viewed from a medical or a surgical standpoint. There is reason to believe that in a very small percentage of cases the resulting peritonitis may become localised, but this happy event cannot be foreseen because it seems that the symptoms are rarely, if ever, proportional to the extent of the peritoneal inflammation. The symptoms of peritonitis in the course of enteric fever are not those of the same accident in a comparatively healthy person. The local pain, for instance, is rarely so severe and may be almost absent, so also is the characteristic position of body. Abdominal movement may be present and ample. The absence of liver dulness as a sign is frequently wanting. But a rise in the pulse and respiration rates and a sudden fluctuation of temperature are almost invariable and of these the former is the most constant. The diagnosis having been made the physician has two courses of treatment open to him, either equally unsatisfactory. The medical treatment amounts to the securing of absolute rest to the intestines in the hope of plastic localisation of the inflammatory process, and this, of course, is best obtained by the free use of opium. If the issue must be fatal this treatment is humane, if nothing else. The surgical treatment is as unsatisfactory as the medical, but nevertheless it is a question whether it is not the duty of the physician to recommend it. It offers a slender chance of recovery and it is possible that as time goes on this chance may be improved. The history of abdominal surgery warrants this hope. If surgeons had allowed the high mortality in the early days of abdominal operations to deter them from operating repeatedly that method of treatment would never have attained the position it now holds. It is difficult, however, to imagine a more unfavourable case for operation than a person suffering from enteric fever, at any date of the disease. The operation itself offers no peculiar difficulties, but in the two that were attempted by us we were glad to get the patient off the table alive. In neither case was the operation performed until from 10 to 12 hours after the first symptom, and it is, of course, possible that if it had been resorted to earlier the result might have been more favourable. The best one can say is that the patients both expressed themselves as feeling more comfortable and quite free from pain, but nevertheless they died four or five hours afterwards.

Harley-street, W.

THE CLINICAL AND PATHOLOGICAL RELATIONS OF THE CHRONIC RHEUMATIC AND RHEUMATOID AFFECTIONS TO ACUTE INFECTIVE RHEUMATISM.[1]

BY ARCHIBALD E. GARROD, M.A., M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; MEDICAL REGISTRAR AND DEMONSTRATOR OF MORBID ANATOMY AT ST. BARTHOLOMEW'S HOSPITAL.

A GLANCE through the table of contents of any modern text-book of medicine suffices to bring home to one the fact that in the matter of the classification of diseases we are living in a period of transition, a period of compromise. The primitive but natural plan of grouping morbid conditions according to the organs or structures specially implicated is still largely adhered to. On the other hand, we find evidences of the dawn of a more scientific system of classification, and we may reasonably expect that before very many years shall have passed away our knowledge will have so far advanced that it will be possible for works to be written in which the various manifestations of each separate morbid process will be so brought together as to form parts of a continuous and comprehensive description. Although this is even now possible to a limited extent it is clear that extensive gaps in our knowledge will have to be filled up before large portions of the field of medicine can be so treated and for the present the time-honoured plan must in many instances be adhered to.

By no department of medicine is this process of transition from one system of classification to another better illustrated than by that which we are this evening met together to discuss. Out of a primitive category of "arthritis" various distinct forms of articular disease have been successively differentiated. The first such sub-division occurred as long ago as the seventeenth century, when Baillou first called attention to the special features of acute rheumatism and drew a distinction between that disease and gout. The next advance did not come until the meeting of the eighteenth and nineteenth centuries, when the further differentiation was made of the conditions now known as rheumatoid or osteo-arthritis from rheumatism by Haygarth and Heberden in our own country and from gout by Landré Beauvais in France. Since then the advance has been more rapid and not a few special forms of articular lesions have been distinguished, such as gonorrhœal arthritis, the arthritides of certain specific fevers, the arthropathies met with in tabes dorsalis and other nervous affections, and the peculiar joint affection to which

[1] The opening paper in the annual clinical debate at the Chelsea Clinical Society on March 12th, 1901.

sufferers from hæmophilia are so liable. We have learnt, moreover, that not a few of these forms of arthritis are results of morbid processes in which the joints do not alone suffer and which have nothing in common beyond the fact that the joints may be implicated in their course.

The progress of our knowledge of the so-called gonorrhœal rheumatism is peculiarly instructive. We find it at first regarded as acute rheumatism accidentally associated with gonorrhœa or awakened into activity by the gonorrhœal infection. Next we meet with the suggestion that it is pyæmic in its nature or is an arthritis of reflex nervous origin set up as the result of urethral irritation. Lastly came an accumulation of evidence, ultimately amounting to complete proof, that this is a specific malady due to the dissemination of the gonococcus through the tissues, as evidenced by the detection of this micro-organism in the inflamed joints as well as in other structures which are liable to be implicated.

An inevitable result of the growth of knowledge along such lines and of the successive recognition of the individual diseases which had previously been grouped together in one common category has been the persistence and survival of notions regarding them which act as a drag upon further advance, and which even at the present day exert a profound influence upon the views which prevail both as to the nature and treatment of the maladies which have this in common—that they implicate the joints. The lay public is still dominated by the older ideas and looks with suspicion upon plans of treatment, both dietetic and medicinal, which do not conform more or less closely to those which have been advocated by successive generations of medical men as desirable for sufferers from true gout, and even in our own profession the notion is still widespread that in spite of fine-drawn distinctions gout, rheumatism, and rheumatoid arthritis are, after all, much of a muchness. We tend too much to assume that a joint affection is gouty or rheumatic in its origin unless it is clearly shown to be of a different nature. Surely the time has arrived when we may strive to shake off this obsession and to assign some definite significance to the terms "rheumatism" and "rheumatic."

Let us seek by careful observation and study to place the classification of diseases which implicate the joints upon a more scientific footing apart from preconceived notions as to their causal relationship to each other. In the course of such investigations any relationships which actually may exist will pretty certainly become revealed, whereas we shall speedily lose sight of such as are merely imaginary.

The terms "rheumatism" and "rheumatic" are perhaps more loosely used and more freely abused than any others in the vocabulary of medicine, but three main ideas appear to underly their various applications—namely, the ideas of pain, of causation by exposure or chill, and of implication of joints. In some so-called rheumatic conditions pain is the only symptom and the use of the word in this connexion is well expressed by the parody of a grammatical rule which I quote from Senator:—

> "Schmerzen, die man nicht definiren kann,
> Sieht man als Rheumatismus an."

The idea of chill and exposure underlies the use of such terms as "rheumatic facial palsy" and "rheumatic iritis" whilst gonorrhœal rheumatism may be again referred to as exemplifying the application of the name rheumatism to a joint affection presenting a certain resemblance to rheumatic fever. In rheumatic fever itself, which may be looked upon as the type of rheumatic affections, we find all the above ideas combined.

It would be a matter of extreme difficulty, well-nigh an impossibility indeed, to abandon the loose employment of these terms in ordinary practice. They have a firm hold upon the laity and the diagnosis is as often as not of the patient's own making. The medical man who attempted to dispense with them altogether would run the risk of being set down as a pedant by his professional brethren and by his patients as an ignoramus who does not know so simple a disease as rheumatism when he meets with it. It is equally out of the question to abandon the use of the term "rheumatism" as a scientific name for the general specific disease which manifests itself most characteristically in an attack of rheumatic fever, but which may assume a variety of forms aberrant from this. On the other hand, it would not seem to be too much to ask that, in medical literature at any rate, the use of the word should be limited to acute rheumatism and to conditions which are believed upon good evidence to be products of the same morbid process or sequelæ of its activity. Even this will be no easy matter. For example, what alternative name shall be assigned to gonorrhœal rheumatism, which certainly does not come within the above definition? The terms "gonorrhœal arthritis" and "synovitis" are far from satisfactorily replacing it, for they express only part of the truth and take no account of the abarticular lesions, such as iritis, pleurisy, myositis, and even gonococcal endocarditis, which may accompany the articular lesions, and, like these, are due to the dissemination of the gonococcus.

Hitherto the recognition of the various truly rheumatic lesions has been arrived at by clinical methods and is based upon their association or sequence. It is upon such grounds that we have become convinced of the frequent rheumatic origin of such affections as tonsillitis, erythema polymorphe, and chorea, but there are indications that before long a surer criterion may be available. There are nowadays comparatively few physicians in this country, and still fewer on the continent, who refuse to recognise the force of the arguments in favour of the view that acute rheumatism is an infective disease, and this quite apart from more recent bacteriological researches which seem to bring us much nearer to the ultimate solution of the pathology of this disease. I need not dwell further upon this point or discuss the question whether acute rheumatism is due to a specific micro-organism or may result from invasion by various pyogenic bacteria. There are some present here who are far more competent to speak on these points, and indeed the council of this society has assumed the infective nature of the disease in the definition of the subject which we are met together to discuss. There are probably few if any here present who will not be prepared to admit that rheumatism is much more than a disease of the joints in the course of which cardiac complications may or may not develop, but is rather a systemic malady in which heart and joints are alike apt to suffer and which may also implicate the skin, subcutaneous tissues, nervous system, and other structures of the body. Nor do I anticipate any opposition to the further proposition that no morbid condition is rightly termed rheumatic which cannot claim, with a good show of reason, to be a manifestation of this disease or a direct sequel of the mischief which it works in the tissues. Let us then proceed to the consideration of the question whether there are any morbid conditions to which the name of "chronic rheumatism" may be correctly applied.

That the rheumatic process may smoulder on for months and even years is beyond question. In children especially we not unfrequently see a veritable rheumatic cachexia, a succession of more acute outbursts being separated by periods of incomplete recovery, during which there may be evidences of still active endocardial or pericardial lesions, or successive crops of subcutaneous nodules may develop, fresh nodules making their appearance whilst those of longer standing are absorbed. In adults an attack of rheumatic fever may be preceded or followed by frequently repeated minor rheumatic manifestations. We know too that an acute attack may leave one or more joints more or less seriously damaged, and perhaps the seats of chronic synovitis. This is, however, the exception and not the rule. Some permanent deformity, such as ulnar deflexion of the fingers, may also follow from repeated attacks of rheumatic fever, and the frequently irreparable damage to the cardiac valves which it leaves behind it is a matter in the daily experience of all. On the other hand, cases are occasionally met with in which extensive crippling and deformity apparently result from an acute rheumatic attack. Cases of this kind occurring in children have been described by Sir Thomas Barlow, Dr. William Pasteur, and others, in which the crippling articular disease has been attended by other troubles which could, without hesitation, be looked upon as truly rheumatic. A similar condition in adults has been described by Jaccoud and other French and Italian authors under the name of "rhumatisme chronique fibreux" in which deformities are present similar to those associated with the name of rheumatoid arthritis. It is difficult to be sure how far the cases so described differ from those which we in this country are accustomed to look upon as examples of rheumatoid arthritis developing as a direct sequel of rheumatic fever.

This brings us by a natural transition to the consideration of the cases usually classed together under the name of "rheumatoid arthritis," the relationship of which to those of acute rheumatism will probably be the main subject here discussed. It would, however, be useless to enter upon such

a discussion without a preliminary consideration of what is meant by the term rheumatoid or osteo-arthritis. I confess to a very strong belief that under this name we are in the habit of confusing together several distinct forms of articular disease the study and discrimination of which offers a very promising field for research. Such discrimination must have its basis in morbid anatomy, aided by other means of pathological inquiry and aided, too, very materially by clinical observation. Indeed, I believe that it is mainly on account of the difficulty of making any adequate study of the pathology of these diseases that our knowledge concerning them still leaves so much to be desired. Let me endeavour to sketch briefly the clinical grounds for my belief that we are here dealing with no single defined malady.

In a female patient, about 30 years of age, or even younger, we witness the onset of a disease affecting many joints and which is specially apt to commence in those of the hands and feet. Of the finger-joints the first row of interphalangeal articulations are specially apt to suffer, they become the seats of fusiform swellings, which are apparently in part due to thickening of the joint capsules and in part to effusion into the synovial sacs. The wrist is apt to be affected early and its contour is lost; bursal swellings add to the deformity of the parts. No osteophytes can be felt, nor is it possible to make sure by radiography or other means that there is any actual enlargement of the ends of the bones. The affection of the joints has a strong tendency to symmetrical arrangement. The disease may progress rapidly, so as to involve almost every joint in the body, and the temporo-maxillary joints and those of the vertebral column are frequently attacked. Muscular atrophy is a pronounced feature, and muscular contracture may lead in time to conspicuous deformities. In some cases the general health is not very materially impaired, but in others the patients are decidedly ill. There may be marked and progressive anæmia and a considerable degree of pyrexia, either of the hectic type or taking the form of bouts of conspicuous febrile disturbance separated by afebrile intervals. The amount of pain experienced is also very variable and has no obvious relation to the severity of the articular affection. In some cases it is the most distressing symptom throughout. In others it is comparatively insignificant.

Turn now to the case of an older woman, say 60 years of age or thereabouts. She also has developed a multiple joint affection somewhat similar in its distribution but slower in its progress and differing markedly in its clinical features. In the hands the terminal inter-phalangeal joints are specially affected, but those of the first row may also be involved, and with peculiar frequency the carpo-metacarpal joints of the thumbs. The affected articulations are obviously enlarged, but the soft structures are but little thickened and the enlargement is clearly due to an increase in size of the ends of the bones. The swellings have not a fusiform shape, but commence somewhat abruptly near the joints. In the knees similar changes with lipping of the bones is met with and some crackling or creaking is clearly felt on movement. The general health is not seriously impaired and it may be confidently predicted that the progress of the malady will be only very gradual. This is not merely a further stage of the condition previously described, for it may be watched commencing with its characteristic features *ab initio*, nor are the differences simply due to the age of the sufferer, seeing that cases of the former type may be met with at an advanced age and those of the latter kind at an unusually early period of life. For convenience of reference these may be referred to as the "fusiform" and "nodular" forms respectively.

Take yet a third case in a younger patient. Here we find but little enlargement of the affected joints, but the deformities due to muscular contracture become rapidly developed and grotesque deformities of the hands result with almost complete fixation. Cases of this third or crippling form *par excellence* are happily much less common. They may be recognised even in their early stages and the outlook in such cases is specially gloomy. One of their characteristic features is the formation of small osteophytes about the affected joints which may be felt as sharp projections beneath the skin.

In addition to such polyarthritic forms there is yet a fourth group of cases in which only one or two joints are involved, as, for example, in the hip-joint affection of elderly people.

The question naturally arises how far the members of these several groups differ in their morbid anatomy and to this question it is difficult to return a definite answer at present. The classical description of the changes in the joints characteristic of rheumatoid arthritis is to be found in every work treating of the subject, and every medical student is taught how the cartilages become fibrillated and eroded and ultimately entirely worn away; how the articular ends of the bones become condensed, ivory-like, and grooved by friction; and how osteophytic outgrowths are formed around the articular surfaces. Of the accuracy of the description there can be no question, but it is mainly based upon the examination of cases of the senile class, and it is permissible to doubt whether it applies equally to all the varieties the features of which I have endeavoured to sketch.

It is probable that some of those who are present this evening may have had opportunities of examining post mortem cases of what I have spoken of as the fusiform group and can supply information bearing upon this question. Observations made upon the younger patients and in the comparatively early stages of the malady would be of special interest. The opportunities for such examinations are peculiarly limited, although the disease is only too common, and it is possible to have carried out a large number of necropsies, in a London hospital at any rate, without having ever had such an opportunity. It is, indeed, remarkable how seldom such patients succumb in our hospitals to acute intercurrent diseases.

The condition described as rheumatoid arthritis in children resembles in many respects the fusiform rheumatoid arthritis of adults. In their clinical aspects the joint lesions are very similar, and in such cases a fatal ending at a comparatively early stage is not very uncommon. In them the changes found in the joints post mortem certainly do not conform in the least to the classical description. The articular cartilages may be intact or may show some pitting at their edges, apparently due to pressure exerted by swollen synovial processes. The chief lesion observed is thickening and undue vascularity of the synovial membrane. There appears to be no tendency to osteophyte formation. I am here quoting from Dr. G. F. Still's description, to the accuracy of which I can myself bear witness, as I have seen the specimens upon which it is based. I strongly suspect that a very similar condition of the articular structures exists in the earlier and more acute stages of the fusiform rheumatoid arthritis of adults.

In a case of the extremely crippling kind in which Dr. Still and I had the opportunity of making a post-mortem examination, the disease, which had been in progress from the age of 17 to that of 37 years, had caused fixation of every limb, so that the patient had been unable to move hand or foot. The case had been diagnosed as rheumatoid arthritis by several highly competent observers, but the conditions found were distinctly at variance with the teaching that one of the special features of the malady is the absence of bony ankylosis, at any rate in the joints of the limbs. In every joint examined some such ankylosis had occurred—not a complete fusion of the articular surfaces, but the formation of bridges of cancellous bone which could be broken down by a slight exercise of force. In the knee-joint the cartilages were destroyed and the bony bridge occupied the position of the cruciform ligaments. Around the articular surfaces were numerous small osteophytes.

In some cases of the nodular kind the changes met with in the finger-joints and elsewhere have conformed more closely to the classical description. It has been suggested that the changes ordinarily described as characteristic of rheumatoid arthritis are not the products of a single definite morbid process, but are merely lesions which are apt to occur in joints which have become the seats of chronic disease of various kinds. There is much to be said for this view. We shall have the opportunity later of hearing the views on this subject of Mr. Arbuthnot Lane who has called attention to the part played by mechanical wear and tear in the production of lesions of this character. Again, as Mr. A. A. Bowlby has pointed out, similar changes in the bones and cartilages are met with in the joints of bleeders who have suffered from the special form of arthritis to which they are liable and which is believed to have its origin in hæmorrhages into the articular cavities. If this idea be well founded we might expect to find the classical changes in the joint structures in any case of rheumatoid arthritis of sufficiently long standing, and their presence will afford no evidence as to the identity of the morbid processes at work in the different cases.

I take it that the main question which we are invited to

discuss this evening is—Whether or no rheumatoid arthritis, or, as I should prefer to say, any of the diseases included under that name, stands in any direct relationship to acute rheumatism. The existence of such a relationship has been warmly maintained by some and equally warmly contested by others. Doubtless we have representatives of both camps among us this evening and we may rely upon full justice being done to the arguments in favour of either view. If such a direct relationship exists we should expect the onset of rheumatoid arthritis to be frequently preceded by an acute or subacute rheumatic attack. It is true that a history of antecedent rheumatic fever, recent or remote, is not very unfrequently forthcoming in such cases, as must inevitably be the case with two maladies both of which are so common. Moreover, the onset of rheumatoid arthritis in its more acute forms may be attended by a considerable amount of febrile disturbance, and at this stage it may be mistaken for rheumatic fever, especially as the initial febrile stage may be followed by a temporary improvement. I believe that this accounts for some of the cases in which a history of recent acute rheumatism is obtained. Lastly, as has been already mentioned, an undoubted attack of rheumatic fever is followed by a chronic joint affection clinically indistinguishable from the fusiform variety of rheumatoid arthritis. A similar result may follow an attack of gonorrhœal rheumatism or even gout, and the question arises whether such secondary rheumatoid arthritis is merely a continuation of the former malady or affords an example of a second disease developing in a subject weakened by the antecedent attack, just as tuberculosis may appear as a sequel of measles. Such cases constitute a very small proportion of the total number. In the great majority of instances rheumatoid arthritis of any form appears as a primary malady and presents its characteristic features from the onset and more often than not the patient has not previously suffered from any troubles which are suggestive of a truly rheumatic origin.

Next as to the development of abarticular rheumatic manifestations in the course of rheumatoid arthritis. In this connexion it should be borne in mind that rheumatoid arthritis in all its forms is most apt to appear at a period of life at which the abarticular manifestations of true rheumatism tend to be less conspicuous. Some of these are almost confined to childhood and puberty and even endocarditis and pericarditis diminish notably in frequency as age advances. Organic cardiac murmurs are undoubtedly present in some cases and some published statistics place their frequency unexpectedly high. Some such murmurs clearly date from attacks of acute rheumatism at some period more or less remote, others may be ascribed to atheromatous changes. Each individual example requires to be considered upon its merits and impressions based upon observation and experience are of at least equal value with statistics Such experience as I have had leads me to range myself with those who hold that sufferers from rheumatoid arthritis show no greater liability to valvular disease than others not so afflicted, and I imagine that few medical men when watching such a case anticipate as a probable event the development of organic heart disease in its course.

In children with so-called rheumatoid arthritis Dr. Still has almost constantly found pericardial adhesions post mortem, but the active pericarditis in which such adhesions presumably have their origin has passed unnoticed. In the crippling case to which reference has been made, in which there was bony ankylosis, the pericardium was also adherent, and it would be interesting to know whether this is a common feature in adult cases. Subcutaneous nodules which bear a striking resemblance to those met with in rheumatic children are occasionally present in cases of rheumatoid arthritis. Those which I have seen have not had the transitory existence of the small deposits of lymph in the subcutaneous tissues of rheumatic patients, and it must not be forgotten that at the period of life at which they have been observed true rheumatic nodules are practically unknown, being confined to childhood and early adult life. We may look forward to hearing Dr. Hawthorne upon this point, for it is one to which he has paid special attention.

The question is one which can only be settled by pathological means, such as bacteriological examination, which in the case of rheumatic nodules has already yielded most interesting results in the hands of Dr. F. J. Poynton and Dr. A. Paine. Indeed it is quite possible that before long bacteriology may throw such light upon the whole problem of the relation of rheumatoid arthritis to rheumatism as will render further discussion of the question futile. Meanwhile it appears to me that the evidence adduced in support of the common causation of rheumatism and any variety of rheumatoid arthritis is not of such a nature as to carry conviction.

If rheumatoid arthritis is not a rheumatic affection, what, then, is its pathology? Clearly this question can receive no satisfactory answer until we know for certain whether we are dealing with one disease or with several diseases. It is quite possible, and even probable, that the several forms differ entirely in their pathology, and that a theory which is true for one form may be wholly incorrect as far as another is concerned.

The nodular or senile cases, with their slow progress and essentially chronic characters, present many features which suggest that the lesion present is of the nature of a degenerative or trophic change in the joints, comparable to the degenerative changes met with in other structures. Such a view of its nature receives support from the striking resemblance of the articular lesions here seen to those met with in the joints of sufferers from certain nervous diseases such as locomotor ataxy and syringomyelia. In these cases, at any rate, there is nothing to suggest a rheumatic origin, and it is in these that the effects of mechanical influences are most marked.

We shall have the advantage of hearing Dr. G. A. Bannatyne, whose name is so closely associated with the bacteriological investigation of the disease under discussion, and who, in collaboration with Dr. A. S. Wohlmann and Dr. F. R. Blaxall, has isolated a definite bacillus from the synovial fluid in a number of cases—a bacillus which they have altogether failed to find in the joints of sufferers from other forms of articular disease. On clinical grounds we should expect that, granting that certain cases of rheumatoid arthritis are infective, the cases concerned would be those of what has been spoken of as the fusiform type. In the similar affection met with in children enlargement of the spleen and lymphatic glands is frequently observed and it is in such cases that the constitutional symptoms tend to be most pronounced.

Among the predisposing causes of the more acute cases debilitating influences take the first place. The onset may follow upon a period of ill-health and attendant lowered vitality, and of late years an attack or a series of attacks of influenza has often appeared to be the predisposing cause of the onset or of the reawakening of the disease from a dormant condition.

The relation of rheumatoid arthritis to gout is another subject of considerable interest and not a little difficulty. Sufferers from chronic gout may exhibit joint changes which in their clinical features bear a close resemblance to those of rheumatoid arthritis of the nodular kind, as, for example, the enlargement of the terminal joints of the fingers known as Heberden's nodes. On the other hand, I can see no valid ground for the belief that gout plays any part in the causation of the more acute forms.

There is certainly still much room for the accumulation of facts, both clinical and pathological, bearing upon the nature of rheumatoid arthritis. Let us first make sure that when we employ this term or any other terms which may eventually replace it we are referring to some one definite morbid condition and not to a congeries of diseases only superficially alike. Then by the diligent piling up of fact upon fact, a task which will provide employment alike for the clinician, the bacteriologist, and the morbid anatomist, we may hope to construct a foundation so solid that the superstructure of theory raised upon it will be capable of resisting any strain to which it may be subjected. In the present state of our knowledge one is justified in taking up an expectant attitude in this matter, and I for my part feel certain of one thing only, which is that I know far less about the pathology of rheumatoid arthritis than I thought I did ten years ago.

Chandos-street, W.

LANCASHIRE AND INEBRIATE REFORMATORIES.—On Feb. 28th a meeting was held at Preston of the Lancashire Inebriates Acts Board, at which a scheme and plans for the reformatory buildings to be erected on Brockhall Farm, Clitheroe, were approved. The "home" system has been decided on in preference to a large central block, each home to contain eight inebriates, with a day-room, attendant's room, scullery, store, bathroom, bootroom, and a separate bedroom for each inmate.

THE TOXICOLOGICAL DETECTION OF ARSENIC AND THE INFLUENCE OF SELENIUM ON ITS TESTS.

BY WILLIAM HENRY WILLCOX, M.B., B.SC. LOND., D.P.H., F.I.C.,
LECTURER ON CHEMISTRY TO ST. MARY'S HOSPITAL.

OF the various tests for the detection of arsenic in minute traces the "Marsh," the "Reinsch," and the "Gutzeit" tests are the most commonly employed. Each test has its respective advantages, but for delicacy and reliability I think that toxicologists would undoubtedly place the carefully applied "Marsh" test easily first, and that next would come the "Reinsch" test and then the "Gutzeit." Certainly by the "Marsh" test one can detect almost infinitesimal amounts of arsenic, even as small as $\frac{1}{100}$th of a grain of arsenic tri-oxide per gallon, and the "Reinsch" and "Gutzeit" tests would not approach this delicacy as ordinarily applied. I propose in this paper to consider some points of importance in connexion with the "Marsh" and "Reinsch" tests and also the influence of selenium on them.

I have adopted the following neat and convenient method of performing the "Marsh" test. Perfectly pure zinc and sulphuric acid are used to generate the hydrogen in a flask provided with an exit tube which is filled with dry calcium chloride, and the escaping dry gas passes through hard glass tubing which has been drawn out into a long narrow portion. The portion of tube which is heated to redness lies within a clay chimney and rests on a clay tube, and the solution to be examined is introduced through a funnel, and the heating continued for one hour. Small amounts of pure sulphuric acid are added from time to time so that a constant slow evolution of hydrogen may continue. If arsenic be present it will deposit on the portion of the tube beyond and commencing at a point about one inch from the clay chimney. It is found that with the purest zinc, quite free from arsenic, and with the purest sulphuric acid, a white deposit is obtained on that portion of the tube which is nearer to the chimney than the arsenical deposit. This deposit occurs with the zinc and acid alone—i.e., in a blank test; also it is much more marked often when various substances are being tested, whether arsenic be present or not. Toxicologists have long been familiar with this white deposit, but I do not think that its true nature has been demonstrated up to the present.

I. *On the nature of the white deposit formed during the "Marsh" test.*—This deposit is sulphur in an amorphous form. If a large amount of pure zinc be used in the "Marsh" test and perfectly pure acid a fairly considerable white deposit is obtained. The deposit is amorphous on microscopic examination. It is soluble in carbon-di-sulphide. If the portion of the tube containing it is fused with pure "fusion mixture" to which has been added some potassium nitrate, on dissolving the mixture in dilute HCl and adding barium chloride solution a definite precipitate of barium sulphate is obtained (I may say that in this test the freedom from sulphur of the chemicals used was first demonstrated). The above tests prove that the deposit is sulphur. It is no doubt formed by the presence of very minute traces of zinc sulphide, which occur in even the purest zinc. The solution of the zinc sulphide in the acid causes the evolution of very minute traces of sulphuretted hydrogen which are decomposed into hydrogen and sulphur in the heated part of the tube, and the sulphur deposits on the portion just outside the clay chimney. I was able to confirm the above in an interesting way by adding a few drops of very dilute ammonium sulphide solution to the contents of the flask in a blank "Marsh" test when very soon a large white deposit formed in the same portion of the tube which had all the characters of the white deposit above described.

II. *The prevention of the white deposit.*—It at once occurred to me that to prevent the appearance of the white deposit one must introduce into the flask some substance which will fix the small amount of sulphuretted hydrogen which is formed. A salt of mercury (because of the insolubility of mercuric sulphide) was used—viz., mercuric chloride. It was found effectually to prevent the formation of the white deposit, but it is at once *prohibited* from use by the fact that it also prevents the evolution of arseniuretted hydrogen if arsenic be also added to the contents of the flask for then no mirror results. This was to be expected from the chemistry of the "Gutzeit" test. I next tried lead salts. These could not be placed in the generating flask because of the action of sulphuric acid on them forming insoluble precipitates, so (1) lead carbonate was placed in the drying tube with the calcium chloride and the test performed. It was found that still a very small deposit of sulphur occurred, but the formation of the arsenic mirror was not interfered with at all should arsenic be present. (2) The evolved gases were passed through potash bulbs containing solution of lead acetate in order to absorb the H_2S evolved, then through a calcium chloride tube, and then through the heated tube. It was found that this answered admirably. No white deposit of sulphur occurred in the portion of tube just beyond the clay chimney, while at the same time the lead acetate solution did not interfere in the very slightest with the delicacy of the test when minute quantities of arsenic were introduced into the flask. The white deposit above described and its nature and prevention are of scientific rather than practical importance. Its presence does not interfere at all with the observation of the arsenical (black) mirror if present, so that I should not advise as a routine practice in the "Marsh" test the passage of the evolved gases through lead acetate solution.

III. *On the influence on the delicacy of the "Marsh" test when substances are introduced into the heated portion of tube (within the clay chimney).*—I think this is of extreme importance to the toxicologist, and it has certainly not been recognised that finely divided substances in the heated portions of tube have a very great influence in preventing the deposition of the arsenical mirror. I first recognised this fact in preparing a series of standard "Marsh" mirrors with solutions of arsenic of varying strengths, when it was at once found that the mirrors were very much smaller if a mixture of carbon and dry sodium carbonate were placed in the heated part of tube immediately over the flame. Indeed, the mirror may be entirely prevented from appearing. In many of the standard descriptions of the "Marsh" test it is recommended to use a mixture of carbon and dry sodium carbonate in the heated portion of the tube in order, so it is said, "to retain any sulphur which may be coming off and which will interfere with the deposition of the arsenic." As a matter of fact, the mixture of carbon and sodium carbonate itself interferes with the deposit of the arsenical mirror and I can positively assert that this mixture prevents as much as nine-tenths of the arsenic from depositing in the mirror form when minute quantities of arsenic are being tested for. It at once suggested itself to me that one of the bodies, the carbon or the sodium carbonate, was responsible for this, but to my astonishment I found that each is able to prevent the formation of the arsenical mirror. Thus, if the heated portion of the tube (within the clay chimney) is filled with either dried sodium carbonate or carbon, and in either case half a milligramme of arsenic tri-oxide introduced into the flask, in each case almost the whole of the arsenic is retained and scarcely any arsenical mirror results, while with nothing in the heated portion of tube a very large mirror resulted with half a milligramme of arsenic.

It next occurred to me to try some inert finely divided substance in the heated portion of the tube instead of carbon or sodium carbonate. Fine sand was used which had been previously ignited. The astonishing fact was demonstrated that sand in the heated portion of the tube (within the clay chimney) caused the retention of almost all the arsenic and only a very minute mirror was obtained. In this experiment half a milligramme of arsenic tri-oxide was introduced into the flask. The sand became perceptibly darkened in colour but no amount of heating would cause it to give up its absorbed arsenic. It seems, therefore, that any finely divided heated substance may cause the retention of the arsenic in the "Marsh" test and perhaps the explanation is of a physical rather than a chemical nature. At all events, the fact is of extreme importance to every toxicologist. The moral is that in performing the "Marsh" test no substance at all should be placed in the heated portion of the tube or the deposition of the arsenical mirror will be prevented.

IV. *On the influence of selenium on the "Reinsch" and "Marsh" tests.*—If the "Reinsch" test be performed on a dilute solution of selenium (10 milligrammes of selenious acid were used) a dull greyish deposit forms on the copper which

if cleansed as usual and ignited in a small test tube gives a white sublimate indistinguishable macroscopically from arsenic tri-oxide, but under the microscope the sublimate does not show the characteristic octahedra and tetrahedra of arsenious acid. If the "Marsh" test be performed on a dilute solution of selenium (10 and 20 milligrammes of selenious acid were respectively used), as correctly stated by Dr. F. W. Tunnicliffe and Dr. Otto Rosenheim,[1] no deposit occurs in the tube at the site where the arsenical mirror usually forms, and the selenium deposits in the flask as a dark reddish precipitate and inhibits the evolution of the hydrogen to some extent.

Now although selenium does not give any result *per se* with the "Marsh" test in the absence of arsenic, yet the astonishing fact was demonstrated that it has a most decided influence on the nature of the mirror if arsenic be also present.

Experiment 1.—If half a milligramme of arsenic tri-oxide be introduced into the flask with 10 milligrammes of selenious acid the resulting mirror is quite different in appearance from that obtained from the arsenic alone. Thus the proximal half of the mirror is of a vermilion red colour, while the distal portion has the usual appearance of the arsenical mirror; but much of the arsenic appears to be retained and the true arsenical portion of the mirror is only about a tenth of the size of that obtained from the same amount of arsenic with no selenium (*vide* Fig. 1).

Experiment 2.—A fresh experiment was performed with five milligrammes of selenious acid and half a milligramme of arsenic tri-oxide; the resulting mirror was of the same nature as the preceding, but the true arsenical portion was larger, being about one quarter the proper size, and the proximal portion was still of a vermilion red colour (*vide* Fig. 2).

Experiment 3.—A fresh experiment was performed with half a milligramme of arsenious acid and one milligramme of selenious acid in flask. Here the influence of the selenium was only slight. No red was detected in the proximal portion of the mirror, and the arsenical portion of the mirror was about from one-half to two-thirds as large as that

FIG. 2.

FIG. 3.

FIG. 4.

Fig. 1. Mirror from one-half milligramme of As_2O_3 and ten milligrammes selenious acid. Fig. 2. Mirror from one-half milligramme As_2O_3 and five milligrammes of selenious acid. Fig. 3. Mirror from one-half milligramme As_2O_3 and one milligramme selenious acid. Fig. 4. Mirror from one-half milligramme As_2O_3 alone. The solid black shows the extent of the arsenic mirror. The vertical shading shows the vermilion selenious portion and the horizontal shading the brown selenious portion.

obtained without any selenium present. Still, there was a definite difference observable between the mirror obtained with half a milligramme of arsenic tri-oxide and one milligramme of selenious acid and one from half a milligramme of arsenic tri-oxide alone. In the former case a proximal brown portion of about half an inch in length preceded the true arsenical mirror (*vide* Figs. 3 and 4).

The above results are of great interest, for they prove that if it is granted, as has been suggested, that the recent beer-poisoning epidemic has been due to selenium and not arsenic, then certainly many instances must have occurred where the selenium had been found in amounts 20 or 10 times as great as the arsenic, as in Experiments 1 and 2 above, and if so, then most characteristic and peculiar mirrors would have been obtained by the "Marsh" test, applied, as it certainly has been applied, to many of the contaminated beers and sugars.

Now it has been my privilege to examine many of the samples of contaminated beer from Manchester and the district round, and from all these samples by the "Reinsch" test characteristic octahedral and tetrahedral crystalline sublimates were obtained of arsenic tri-oxide evidently (since selenium does not give the characteristic crystalline sublimate). By the "Marsh" test in no case were the curious characteristic mirrors obtained, such as are given by selenium with small amounts of arsenic (Experiments 1 and 2, Figs. 1 and 2). Hence I think that these facts conclusively prove that the poisoning could not have been due to selenium primarily and arsenic secondarily, as has been suggested, for the mirrors obtained by the "Marsh" test on the contaminated samples would have at once demanded attention by their most remarkable appearance.

St. Mary's Hospital, W.

[1] THE LANCET, Feb. 2nd, 1901, p. 318.

SEPTIC DISEASE IN GRADUATED ATTACKS IN THE SAME PATIENT.

BY J. SNOWMAN, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.

THE following case affords an interesting study of variations in the development of the same disease in the same individual at different times but under similar predisposing circumstances. The facts concern a healthy female who was 34 years of age when her present history began five years ago. She was then lying-in with her sixth child and had three or four severe rigors between the third and sixth days. As these rigors, in which the temperature rose to 105° F., were not accompanied by any untoward abdominal or uterine symptoms, and as convalescence was established normally, the condition was regarded as one of those vague cases of puerperal pyrexia of uncertain origin. These cases, which have been variously attributed to milk fever or nervous disturbance, are now considered by the best authorities to be septic in nature and are to be interpreted pathologically as the successful resistance of the healthy organism against an attack of the micrococci of septicæmia.

The patient became pregnant again towards the middle of January, 1898. After seven weeks' amenorrhœa she aborted. The abortion was attended by severe hæmorrhage so that no traces of the embryo were to be detected in the portions of the ovum which were expelled piecemeal. When the patient was first seen the uterus could be felt midway between the pubes and umbilicus; it was soft and compressible and evidently filled with blood-clot. The temperature was 102° and the cervix admitted one finger, but the internal os was closed. The blood contained in the uterus was expressed and its cavity irrigated with Condy's fluid. For two days all went well, but on the third day the patient had a rigor, with a temperature of 104°; there were abdominal pains, but no real tenderness was present. The rigor was followed by profuse sweating. The external os still admitted one finger, and the uterus was enlarged, its contents being chocolate coloured. Irrigation of the uterus was continued. The temperature became normal during the day, but on the following evening there was another rigor and the temperature rose to 105°. The uterus was then thoroughly explored with the finger, counter pressure being made over the hypogastrium. By this manœuvre a few shreds were removed. The next few days were uneventful, but bruises gradually appeared on the hypogastrium where the fingers had exerted pressure and on the vulva from the pressure of the thumb of the examining hand. The temperature rose to 103° and these bruises, four in number, became large inflammatory indurated swellings. The uterine condition was now quite healthy, but three of these local swellings suppurated and required free incisions to give vent to the pus. After

this the temperature gradually fell and the patient soon recovered.

These facts may be interpreted to mean that the patient was threatened with septicæmia in this abortion, as she had been in her previous confinement. It may be that her tissue resistance would again have repelled the attack of the streptococci; it may be that the digital curetting of the uterus after the second rigor saved the situation. In any case the micro-organisms of suppuration were in the blood producing a toxæmia, but instead of proceeding to a general pyæmia they spent themselves in the *loci resistentiæ minoris* afforded by the bruised areas of the hypogastrium and vulva, and there their specific action was exerted.

The next pregnancy of the patient also terminated abruptly in an abortion, but unfortunately the septicæmia with which it was again attended did not abort. The patient's last menstrual period ended at the beginning of September, 1899. She then had amenorrhœa for five weeks, when a sanious discharge made its appearance and lasted for three weeks, culminating in the expulsion of a clot on Nov. 5th. On that day the patient experienced a severe rigor. On making a vaginal examination the following day it was found that the cervical canal was open and the uterus distended to the size of a three months pregnancy. The temperature was then 101°, but that night there was another rigor. At 6 A.M. on Nov. 7th a complete abortion took place, the ovum being expelled entire, and it was a perfect specimen of six and a half weeks' growth. The temperature was then 99°. On Nov. 8th there was another rigor; the following morning the temperature was 102°, there was slight œdema of both legs, some fulness in the ankles and knees, with tenderness on deep pressure. There was also pain in the right shoulder-joint severe enough to prevent movement. The temperature fell to 99° the next day, but rose gradually to 104° in the afternoon, while the pain and swelling in the left ankle and knee increased. The condition of the left knee became much worse and assumed the appearance of very acute osteo-arthritis; the temperature rose to 105·2°. For the next few days it fluctuated between 101·5° and 104°, but the swelling of the knee and ankle decreased somewhat, so that free passive movement was possible in the latter joint. Some erythema which had been present over the ankle disappeared completely. The circumference of the left thigh just below the apex of Scarpa's triangle was two inches greater than that of the right in the corresponding position. But with the indications of apparent subsidence of the mischief in the lower limb redness and effusion began to appear over the right wrist, marking out at first the synovial sheath superficial to the joint. This condition increased and the well-defined redness gave way to an œdematous surface of a purple hue. With this a similar patch, possessing all the physical characters of erysipelas, began to appear over the left olecranon. The elbow-joint was not involved. While the swelling over the right wrist was becoming fainter and less dusky the cutaneous inflammation over the elbow was spreading. Meanwhile the left ankle became quite free in its movements, though œdema of the foot persisted; there was still pain on attempting to extend the knee from its flexed position, though it could with difficulty be straightened out. Neither at this time nor at any time during the whole course of the illness was there any uterine trouble. That organ was freely moveable and there was no induration in the pelvic cellular tissue. During the next few days the erysipelatous patch over the left elbow crept up as far as the shoulder and half-way down the forearm; then it began to subside gradually, leaving the limb considerably increased in size. The effusion over the right wrist still persisted and it became obvious from the general condition and the temperature chart that the swelling had suppurated. On Nov. 27th the swelling was opened under A.C.E., and about two ounces of thick curdy pus were evacuated, hot fomentations being subsequently applied. For the next few days there was favourable progress, the incision was healing well and the temperature kept below 101° F. Then the leg began to be extremely painful and the œdema increased. Occasionally the pain was agonising—neither active nor passive movement was possible. At this time there were decided bogginess and distension of veins over the posterior surface of the left elbow and pain in one definite spot on the olecranon process. In the interval between the olecranon and external condyle there was a distinct sense of fluctuation and there appeared to be inflammatory exudation from this area extending lower down the limb, but the movements of the joint were quite free. The general state of the patient pointed to more pus in the body and the physical signs of the elbow region seemed to localise it there. But an incision down to the bone in the œdematous area failed to reveal any purulent collection. As the patient was under an anæsthetic the knee-joint was explored by means of a syringe but only clear fluid was drawn off. The syringe was again inserted into the œdematous thigh, in the lower and outer third, and on this occasion some purulent fluid was removed. The puncture was enlarged by an incision one and a half inches long and about three-quarters of a pint of dark sanious pus escaped. A counter opening was made towards the posterior surface of the limb and a large drainage-tube was inserted. This operation was performed on Dec. 14th and from this time matters improved considerably, but only for a few days. It became obvious that the drainage was imperfect and that the abscess cavity was bagging. The temperature rose again to 103°, the pain in the knee increased, and the discharge practically ceased. On Dec. 28th the patient was again anæsthetised and the knee explored with a syringe; there was no pus and but very little clear fluid. On pushing a long probe downwards from the lower incision on the outer side of the thigh it was found to penetrate the joint, and its end could be felt projecting at the inner side of the knee. Through the original incision in the thigh about two inches of bare femur could be felt. This incision was extended downwards and a counter incision was made on the back of the limb, a drainage-tube being passed right through. Another incision was made along the course of the probe inserted in the limb. A further incision was made into the knee-joint from the outer side and it was found that adhesions were forming between the articular cartilages. This incision was stuffed with iodoform gauze and the limb fixed on an interrupted back splint. The drainage was now free, and after a couple of days the temperature fell to normal, and with one or two occasional elevations to 100° remained so permanently. Pus discharged in small quantities from the incisions for about three weeks, and when the tubes were completely removed the wounds healed absolutely well without leaving sinuses. A poroplastic felt splint was fitted to the knee and the patient was encouraged to sit up in bed. Massage and passive movements were begun. Convalescence was very tardy owing to œdema of the leg and foot, with a markedly cyanotic condition of the latter. On March 9th, 1900, the patient sat up out of bed for the first time, and from this date improvement was steady, so that now she is in perfect health with the exception of some ankylosis of the knee.

The foregoing is, of course, the history of a typical attack of pyæmia ending in recovery and forms the climax of the gradual series of septic disease from which the patient has suffered. The interest of the case is certainly considerable, and looked at from the point of view of its relation with the preceding attacks, similar in nature but different in degree, gains in importance. It is perfectly clear that this patient possesses the power of elaborating from her own tissues an antitoxin which is inimical to the growth of the streptococci of suppuration. Their first invasion was met by an immediate production of antitoxin and the only indications of a struggle were the pyrexia and rigors. On the second occasion the mobilisation of the chemical forces of the body was less rapid, there were weak spots in the defence—i.e., the bruises of the impressed finger-marks—and here local suppuration occurred. But still the general preparations of tissue resistance proved to be good and a pyæmia was warded off. On the third occasion, however, either from the intensity of the attacking poison or delay in the elaboration of the defensive antitoxin, the resistance was slow and there was time for true embolic or pyæmic processes to take place before success was achieved.

The entrance of the cocci must obviously have been through the genital tract, and in the last illness was not the result of contagion in the ordinary sense, as the first rigor occurred before any vaginal examination had been made. The case demonstrates that the seat of inoculation may entirely escape the local processes of the disease, and this is a point which should be remembered in making a diagnosis when puerperal pyrexia is not attended by inflammation of the pelvic cellular tissue, peritoneum, or uterine appendages. Incidentally some light is shed on the pathology of erysipelas, for the occurrence of absolutely typical patches of this condition warrants us in discarding the time-honoured doctrine that this disease must be preceded by a breach of surface to serve as the site of inoculation.

Erichsen records a case of pyæmia in which a collection of pus was found in the intermuscular strata of the lower third of the thigh. There was a free communication between the abscess cavity and the knee-joint and the author concludes that the joint had suppurated and its contents extravasated into the tissues of the limb. In the present case it will be remembered that the probe inserted into the abscess cavity passed right down into the joint. In dressing the limb it was seen that all the pus came from below upwards, and when drainage was deficient pus could only be obtained on making pressure in that direction. Assuming that in the present instance the joint suppurated and that the pus found its way into the tissues of the thigh the subsidence of the effusion in the knee and the increased circumference of the limb are easily explained.

It is important to note that this case narrowly escaped record as an example of cure by anti-streptococcic serum. About the fourteenth day of the disease, when its septic nature had long become obvious and the condition of the patient was exceedingly grave, the temperature remaining between 102° and 104°, it was determined to use this serum, and preparations were actually made for this purpose. At the very last moment, however, in view of the fact that so far there had been no actual evidence that it was a pus-producing organism which was at work, the injection was abandoned. The very next morning the temperature had fallen from 104° to 99°. If the injection had been administered it would have been held responsible for this sudden drop and would doubtless have been regarded as having influenced favourably the whole course of the disease. The treatment of the case on ordinary surgical lines shows that it was not any antitoxin artificially injected into the tissues which determined recovery, but the actual production of the antitoxin from the constituents of the blood of the patient.

PAROTITIS AFTER ABDOMINAL SECTION.

BY BERTRAM ADDENBROOKE, M.D. DURH., M.R.C.S. ENG., &C.

IN THE LANCET of Jan. 19th, 1901, p. 176, Dr. William Elder records a case of parotitis after abdominal section, a brother of the patient who was living in the same house having had an attack of parotitis epidemica (mumps) 49 days previously. This, considered in contrast with cases under my care where two cases occurred in other members of the family after parotitis in a patient, a sequel to abdominal section,[1] is, as Dr. Elder remarks, very interesting, and although he is of opinion that it is doubtful whether his case was one of parotitis (from metastasis?) or true mumps, I venture to think that the previous occurrence of parotitis epidemica in the house was only a coincidence. There is, however, one very striking point of resemblance between the cases reported by Dr. Elder and by myself. It is this: three days after the operation on his patient parotitis developed, and as I recorded in THE LANCET of Dec. 29th, 1900, there was the same duration of time in the case under my care and, furthermore, in the two other members of the family who subsequently suffered from parotitis there was the same interval between the exposure to infection and the supervention of parotitis as in the abdominal cases—namely, three days.

DORSAL DISLOCATION OF THE FIRST PHALANX OF THE LITTLE FINGER.

BY EDWYN M. RIDGE, M.R.C.S. ENG., L.R.C.P. LOND.

HAVING seen the article on Dorsal Dislocation of the First Phalanx of the Little Finger by Mr. Harold L. Barnard in THE LANCET of Jan. 12th, 1901, p. 88, I think it would be interesting to record a case of what he calls a "complete complex dislocation" which came under my notice shortly afterwards. A youth, aged 19 years, came into the receiving-room of the Poplar Hospital for Accidents where repeated attempts were made at reduction by the ordinary methods. He gave a history of falling backwards and in putting out his hand behind him to save himself he bent his finger backwards. Further attempts were made under an anæsthetic without avail, and then the simple operation suggested by Mr. Barnard was resorted to with very favourable result, the patient making an uneventful recovery, good movement and power being already attained. The way in which the accident occurred in the case which I have described seems to me much more likely to happen frequently than that which Mr. Barnard alleges.

SERUM TREATMENT OF DIPHTHERIA ON THE FOURTH DAY OF THE DISEASE.

BY RALPH S. MCD. PULLEN, M.R.C.S. ENG., L.R.C.P. LOND.

ON a Wednesday evening recently, at 11 P.M., I was sent for to see a child, aged four years, who was stated to be suffering from a "sore-throat." The patient had been taken ill on the previous Sunday. I found the tonsils covered with membrane and bleeding. There was a nasal discharge. Such difficulty of breathing as existed was due to nasal and not to laryngeal obstruction. The temperature was below 100° F. At midnight I administered an injection of serum under the skin of the abdomen. The patient was comfortable and slept during the night and in the morning appeared somewhat brighter as regarded her general condition. I advised her removal to hospital where she received a second injection at 1 P.M. on the Thursday. The membrane disappeared with marvellous rapidity and the general improvement was very marked. She has made a good recovery up to the present time.

I communicate this case as I consider the interest lies in the successful issue of an injection at such a late period—some 96 hours—after the invasion of the disease.

WESTMINSTER HOSPITAL.

A CASE OF RECURRENT APPENDICITIS COMPLICATED BY GENERAL SEROUS PERITONITIS AND EFFUSION.

(Under the care of Mr. W. G. SPENCER.)

PROBABLY the rarest complication of inflammation of the appendix is a serous—i.e., non-purulent—effusion and this is due to the fact that if an appendicitis is sufficiently severe to cause any peritonitis this will be due to the passage of micro-organisms through the wall of the appendix, and these micro-organisms are nearly always pyogenic. If, however, merely toxins pass into the peritoneum or microbes of a mild type then a non-purulent peritonitis may arise which may disappear after drainage. It would have been of interest to have had the result of a bacteriological examination of the peritoneal fluid in the following case, and an examination of the sputum in the pneumonia might have shown an identity in microbic infection between the peritonitis and the pneumonia. For the notes of the case we are indebted to Mr. A. Whitehouse, dresser.

A well-nourished generally healthy man, aged 24 years, was admitted into Westminster Hospital on Dec. 29th, 1900; there had been severe pain in the abdomen and repeated vomiting for the previous 24 hours. He had had a right inguinal hernia operated on by Mr. W. Anderson at St. Thomas's Hospital. In November last the patient had been suddenly

seized with pain all over the abdomen and had vomited all one night, after which he was admitted to a medical ward in Guy's Hospital. He was placed on a milk diet, the pain subsided, and he left the hospital being told that he had had an attack of appendicitis.

After admission to Westminster Hospital repeated bilious vomiting occurred, the temperature was 100·6° F., the respiration was 24, and the pulse was 108. The abdomen was distended by free fluid without gas, there was pain all over, but the patient referred the most severe pain to McBurney's point. Nothing was to be felt in the right iliac region or in the rectum. The bowels had been regular. The diagnosis made was general septic peritonitis following recurrent appendicitis and perforation.

On making an iliac incision nothing abnormal was found outside the peritoneum. On incising the peritoneum straw-coloured serous fluid poured out abundantly. The appendix was found freely floating over the pelvic brim and was not thickened. Its surface, as well as the intestines within view, simply showed dilatation of the capillaries on their serous surface without any lymph or adhesions whatever. The appendix was excised and a rubber tube was passed through the wound down into the pelvis.

Serous fluid drained freely away for three days, and the tube was removed on the fourth day. The pulse, which reached 130 on the first day, became normal on the fifth. The temperature fell at once to normal. The bowels were opened freely by calomel on the fifth day, after which the abdomen remained soft and free from tenderness. Thirteen days after the operation, whilst lying in a bed beside the fireplace, he had an attack of right basic pneumonia. The temperature returned to the normal five days later and the rusty sputa soon became muco-purulent. The patient was kept in bed for a month after the operation and was discharged on Feb. 7th apparently quite well.

The appendix, on being slit open, showed a constriction of the lumen at the junction of its middle and distal third, it contained fæcal mucus but no concretions, and the inflammation had not increased the thickness of its wall to any noticeable extent.

Remarks by Mr. SPENCER.—Among the many varieties of appendicitis the above case is a rare instance. Before the operation the condition was supposed to be one of general septic peritonitis following upon perforation. There was nothing to account for the general serous peritonitis unless the attack of pneumonia during convalescence points to an individual predisposition to catarrhal inflammation. The peritonitis was arrested by the drainage.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

A CASE OF LATERAL LITHOTOMY SUCCESSFULLY PERFORMED IN A SMALL BOY FOR THE REMOVAL FROM THE BLADDER OF A STONE OF UNUSUAL DIMENSIONS AND WEIGHT.

(Under the care of Mr. T. VINCENT JACKSON.)

THE lateral operation of lithotomy is becoming every year more rare, and rightly so, for we have in lithotrity a method which in skilled hands gives better results; but lateral lithotomy was especially successful in boys, for the mortality ranged from 2 to 4 per cent. There are even now some cases of vesical calculus in which a cutting operation offers a better chance of success, and we agree with Mr. Vincent Jackson that the large size of the stone in the following case was a strong argument in favour of lithotomy.

A boy, aged seven years, residing at Cannock, on May 2nd, 1900, attended as an out-patient at the Wolverhampton and Staffordshire General Hospital with symptoms of gravel, and on a vesical stone being detected by sounding he was admitted into the hospital. The family history narrated by the mother gave no indication of a tendency to gout, uric acid, renal or vesical trouble. The boy's dietary had been simple, butcher's meat not having been taken in excess, milk in moderation being the chief fluid. Micturition had been painful since the patient was four years old and this symptom had increased in frequency, duration, and intensity. The microscopic examination of the urine indicated the presence of pus, but no blood corpuscles, crystals, or renal casts. The boy was physically small for his age but was not unhealthy-looking. On the 11th (the patient being blindfolded) a soft catheter was passed into the bladder, its contents flowing away; then two or three ounces of warm sterilised water were injected and left in and the catheter was drawn out. Next the urethra was fully distended by a local anæsthetic (1 per cent. of eucaine and 2 per cent. solution of suprarenal capsule). After waiting a while a boy's lithotrite, the largest the urethra would admit, was with difficulty finessed into the bladder and a stone, which evidently was a hard one and of unusual bulk, was with careful manipulation seized by the points only of the lithotrite, the blades of which had to be separated for fully two inches. It was determined to perform lateral lithotomy, and, chloroform being given, this was accomplished with greater facility than Mr. Jackson expected, the operation being commenced and completed under two minutes; no artery spurted. A glass tube was tied in the bladder and removed two days later. On June 3rd, when the patient was discharged from the hospital, the wound had healed, the lad having been out of bed for the past week. The stone weighed 2 ounces 2 drachms and was fairly smooth on the surface. The actual measurements were as follows: circumferential length, 6⅛ inches; circumferential breadth, 5 inches; and thickness, 1¼ inch.

Remarks by Mr. JACKSON.—Lately I have been reading with much surgical pleasure "The Stone Number" of the *Indian Medical Gazette* (August, 1900), kindly lent by Dr. D. F. Keegan, now wintering in the Tyrol. Dr. Keegan's contribution is worth any time spent over it; it is historical of the rise, progress, and the statistical position of "lithotomy" (I wish this word was dropped and "lithotrity" was substituted) and the record of 500 cases with a mortality of 11 and a death-rate of 2·2 per cent. is so reassuring that I do not wonder that the operation in children is much more generally adopted at home than it used to be, and I am convinced that for a stone in the bladder of a size not prohibitory crushing rather than cutting is the operation which should be resorted to if the local conditions are favourable and a careful preparatory examination brings to the surface no prohibitory conditions either in the kidney or bladder. Off hand, as a summary of what is in my mind as conditions which may be put down as a bar to crushing, I may mention renal disease (this is sometimes very difficult to fathom and its non-detection is one of the disasters sequential to lithotrity—of Dr. Keegan's 239 cases five succumbed from advanced kidney disease); large encysted and hard oxalate of lime stones; deposits of calculous material on the inner walls; a sacculated bladder, cystitis, and putrid urine. Here I may quote from THE LANCET[1]: "No surgeon can doubt after reading our contemporary's special number that at the present time the safest and the most speedy method of removing a stone from the bladder in nearly every case is Bigelow's operation of lithotrity." Although this is quite true and is a governing statement of what the surgical treatment of stone in the bladder of boys should be, yet let me point out that as a signpost I extract from the *Indian Medical Gazette* for December, 1886, p. 356, a case under the care of Dr. R. Caldecott in which the patient died shortly after a crushing operation, the cause being found post mortem to be peritonitis induced by a sharp-pointed fragment of stone having pierced the wall of the bladder and lying in the rent. A second death, two days after operation, followed lithrotrity for an oxalate of lime stone weighing 242 grains, the operation lasting 71 minutes. Lithotomy might have saved these lives.

I do not consider that in the case which is reported there is much room for controversy as to the most fitting and safe surgical procedure to be adopted for the cure of the little boy. A surgical authority of large experience in the operative treatment of vesical calculus has enunciated the dictum that every stone weighing two ounces and over is to be regarded as a large stone and dealt with accordingly. I confess that I jibbed at an attempt to perform lithotrity, and fixing on lateral lithotomy I performed that operation, and the rapid and easy recovery of the patient is the best justification of the selection.

[1] THE LANCET, Jan. 19th, 1901, p. 193.

HEALTH OF NEWQUAY.—Dr. A. Hardwick, the medical officer of health of Newquay, Cornwall, reports that during the year 1900 the death-rate was 10·4 per 1000, being the lowest rate for the past six years. He states that the population was estimated at 2600. There were 207 cases of infectious diseases notified during 1900, of which 194 were measles.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Discussion on Immunity.

A MEETING of this society was held on March 12th, Dr. F. W. PAVY, the President, being in the chair.

Professor SIMS WOODHEAD opened a discussion on the subject of Immunity. After referring to the magnitude of the subject he remarked that though some observers might have modified their opinions during the past eight years as to the exact part played by Metchnikoff's phagocytes, all would agree that without his epoch-marking work it would have been impossible to discuss other theories with any degree of intelligence, for upon the phagocyte theory the "side-chain" theory of immunity and antitoxin production depended for its inception and conception. He mentioned that whilst in Edinburgh he and Dr. Cartwright Wood had carried out a series of experiments on the production of immunity by means of soluble products, in which they thought they obtained a condition in which special activities of the cell were drawn out, comparing the cell to a many-faceted body, each facet of which was enabled to withstand the attacks of poisons or substances which they had been trained to resist. He referred to the theory of separable enzymes and external metabolism, to Bouchard's "antibodies" produced by all cells, and then spoke of Behring's more systematic observations on the action of toxins in producing antitoxins. Referring to the "overflowing" of antitoxins from the cells he maintained that this was comparable to the overflowing of the toxins from the bodies of organisms. There were some "properties" or "functions" which appeared to be separable only with great difficulty from the bodies of micro-organisms, so also there might be certain properties or functions which were more intimately bound up in the protoplasm of the cell. In so far as these were distinct he maintained that immunity was distinct from antitoxin production, but in so far as they were interchangeable and collateral immunity and antitoxin production must run side by side. He referred to Bütschli's theory of the structure of protoplasm and the relation of metabolic products to the protoplasm, and pointed out that, if they accepted this theory, then immunity and antitoxin formation, though not the same, must in many cases be very nearly related. He then explained Ehrlich's idea that in regard to immunity the toxic action of a toxin was practically a matter of little importance, in so far as a toxin did not produce its antitoxin by virtue of its toxic power, but because on introduction into the animal body in such a way that its immediate destruction was avoided it was assimilated—i.e., it entered into very close combination with the protoplasm of the cell, and as a result of this assimilation they had the production and overflow of antitoxic substances from the specially stimulated cell. But the production of immunity against disease appeared to be merely a part of a general process going on where albuminoid substances were being assimilated by living protoplasm. In this connexion he referred to the late Dr. Walter Myers's experiments on Immunity against Proteids[1] and indicated their importance in regard to the specific effects produced by proteid poisons in determining immunity and antitoxin production. The study of the ferments formed by pathogenetic organisms could perhaps be best advanced by continuing the study of the non-pathogenetic enzymes, hæmolytic substances and the agglutinins, in connexion with which Ehrlich, Pfeiffer, Gruber, Durham, and others had already obtained such brilliant results. Ehrlich had found that the toxic molecule could be so modified that whilst losing a great part of its lethal activity it still retained its minimising influence on the cells. Dr. Cartwright Wood had proved that it still retained its power of stimulating the cells to produce antitoxin, these observers having their work confirmed by Ritchie. The molecule able to become assimilated by the cell still retained its characteristic power of forming "antibodies." Bound up with the theories of immunity and the source of antitoxin was the question of the nature of antitoxin. One of the original theories put forward by Roux and Vaillard and afterwards emphasised by Ehrlich, that antitoxin was the result of the special stimulation of certain cells, received support from a very large number of observations made during the preparation of antitoxin in the fact that it was only where there was marked reaction, especially of a local character, that there was any increase in the amount of antitoxin produced. He laid special stress on the local reaction because the toxin injected must exert its greatest stimulating power — in fact, one might almost say its only stimulating power—on those tissues with which it came directly in contact, that was before it became mixed with any large quantity of lymph or found its way into the circulation, in which, at the temperature of the body, the combination of toxin and antitoxin went on with great rapidity, the amount of antitoxin in the blood of some of the animals under treatment being thousands, and even tens of thousands, of times the quantity required to neutralise the whole of the toxin injected. Acting locally, however, it might be readily understood how the toxin, given in gradually increasing quantities, could still continue to stimulate the connective tissue cells to the production, excretion, and overflowing of the antitoxin into the surrounding fluids. Behring drew attention to the fact that the tissues might become hypersensitive even when large amounts of antitoxin were present. Such a condition they would expect to find in the more highly organised tissues for which the toxin had a special affinity. Here there might be a kind of local hypersensitiveness induced through want of equilibrium due to over-stimulation. The amount of antitoxin might be great, quite sufficient to protect against toxins introduced in the ordinary way, but inadequate, because it could not all act at one place at once, to counteract the local action of poison specially introduced in bulk and at one point. As regarded the amount of antitoxin produced he might mention that taking the lethal activity of a toxin to represent its quantity and neutralising power he had records of the formation of 20,000 and even 40,000 times as much antitoxin as he used toxin. This was remarkable and indicated one of two things: (1) most probably that the immunising or antitoxin stimulating substance was of the nature of a toxoid or of a proteid molecule that was not highly toxic, and (2) that the process of antitoxin formation went on long after the special and specific stimulus had been removed. The idea that antitoxin was merely a modified toxin was strongly dissented from. In support of this he would put forward the above facts and also the observations made by Martin and Wood as to the nature of albumoses. He himself had found that these albumoses, whatever might be their exact character, were not specially toxic, but, on the other hand, they were in no sense of the term antitoxic. They had the power when introduced into the body of setting up the formation of antitoxin and also the power of producing a very definite immunity. They had also evidence of the cellular origin of antitoxin in the way in which it continued for long periods in the fluids of the animals in which it was produced, long after all trace of toxin had disappeared, although it might be and was thrown out as a foreign body from animals into which it was ingested. The discovery of the linking-on of toxin to proteid bodies, and particularly to special proteid bodies, and the assimilation by cells, with the consequent appearance of anti-bodies, was one of the most remarkable contributions to their knowledge of immunity that had yet been made. He then dealt with the question of polyvalent sera and pointed out how important were Durham's observations in connexion with the subject of relapses. Whether they were justified in accepting this theory of specific reaction or that put forward by Dr. Cartwright Wood, they were gradually working out the extreme specificity of immunity in most cases of disease. A general insusceptibility there was in many cases, but this could usually be increased at the expense of a marked protection against specific bacteria and bacterial poisons. He should leave the specific immunities to be discussed by those who would follow and who had paid special attention to specific diseases.

Professor A. E. WRIGHT did not think with Professor Woodhead that the theories of immunity which were propounded by Metchnikoff and Ehrlich respectively could be regarded as theories which merged into each other. Metchnikoff's phagocytosis theory was designed to explain the bactericidal effects observed in the organism. An explanation was found for these in the assumption that the organism of the higher animals corresponded to

[1] THE LANCET, July 14th, 1900, p. 98 et seq.

a colonial aggregation of monocellular organisms, some of which in the form of white blood corpuscles still possessed the properties and exercised the functions of the original free-living monocellular organisms. There was no doubt that the fact that white blood corpuscles emigrated towards the seat of a bacterial invasion and that the bacteria were afterwards found in the interior of the white blood corpuscles and often in a condition of disintegration was brought much nearer to the understanding by the theory propounded by Metchnikoff that the bacteria were incorporated and digested by phagocytes. On the other hand, when they turned from the consideration of the inflammatory and bactericidal effects seen in the organism to the consideration of the problem of antitoxin formation in the organism, the theory of immunity propounded by Metchnikoff failed entirely to provide anything in the way of an acceptable explanation. Metchnikoff's view that the white blood corpuscles voided antitoxins into the body fluids under the stimulus of a toxin might, it was true, be crudely compared with the ex-voiding of mucus which took place when a snail was brought into contact with alcohol, the toxin of the yeast plant, but the mental picture would not explain to them the fact that a number of different specific antitoxins were produced in the organism in response to the introduction of a series of different toxins. This last, as distinguished from the problem of the bactericidal effects exerted by the organism, was the problem that Ehrlich set himself to solve. He asked himself not how it was that bacteria were destroyed in the body, but how it was that when a guinea-pig was injected with a poisonous element—and in some cases the poisons in question were poisons which were brought in contact with the responding guinea-pig for the first time in the history of the individual and the race—an antitoxin was produced whose chemical properties fitted those of the poison as accurately as a key fits into its corresponding lock. Professor Ehrlich had drawn attention to the fact that such antitoxin production took place only when the poisons which were injected were albuminous substances or substances allied to them—when, in other words, the poisons were such as might, the speaker thought, be conveniently denoted as "poisonous foodstuffs." Such "poisonous foodstuffs" would be taken up into cells by virtue of the fact that there were in the cells molecular groups—side-chains—which possessed chemical affinities for the substances in question. Following upon this "occupation" of the side-chains by the poisonous foodstuffs there would occur, in the opinion of Ehrlich, a re-formation of similar side-chains in the cell, which would gradually transform itself into a process of "internal secretion," the product of secretion being a substance identical in its chemical affinity with the toxin with the original "side-chain" constituent of the cellular protoplasm. The further question as to what kind of cells contained side-chains which could be thrown off as antitoxins had been somewhat incompletely treated by Ehrlich; for while he had emphasised the fact that the cells whose side-chains were affected by the toxin were those which responded with a formation of antitoxin, he had, through a certain want of preciseness in the setting forth of his theory, allowed it to be understood that the response took place only in the group of cells which the clinician recognised to be affected by the poison. Such would be the case only with "monotropic" poisons—i.e., poisons which affected only one variety of cell. In the case of "polytropic" poisons—and a very large number of poisons must come under this category—the chief response—i.e., the chief antitoxin production—might take place in tissues which the clinician could not discover to have been affected. Under this category would come the white blood corpuscles which when affected by the toxin would naturally be involved in the production of antitoxins. It was, in the opinion of the speaker, only in this respect, and even here only incompletely, that the theory of Metchnikoff conformed with Ehrlich's theory of the production of antitoxins. Professor Wright then passed to consider the possibility of applying the theory which Ehrlich had propounded to explain the production of antitoxin in the system, to the explanation of the production of bactericidal substances in the blood. A comparison could be established between the two processes when it was considered that the constituents of the bacterial protoplasm were in many cases poisonous and that these constituents passed into solution in the lymph when bacterial cultures were injected into the subcutaneous tissue. An analogy was thus immediately established between the injection of toxins and the injection of bacteria. Similarly an analogy emerged between the response in the form of an antitoxin formation which took place after the injection of a bacterial toxin and the response in the form of a production of anti-bacterial substance which had in the case of cholera and typhoid fever been observed by the speaker to take place in the case of bacterial injections. According to these the essential difference between an anti-bacterial substance and an "antitoxin" (using the term in its ordinary sense) would be that the substance produced in the latter case had a chemical affinity for the substances contained in bacterial filtrate, while the substance found in the former case had an affinity for a substance which was a constituent of the bacterial protoplasm. When it was considered that all substances—not being food-stuffs—which had a chemical affinity for a component of the living protoplasm were by definition poisons for that protoplasm, the circumstance that an antitoxin to a constituent of the bacterial protoplasm was capable of functioning as a bacterial poison was easily explained. Taking his stand upon the identification of anti-bacterial substances with antitoxins (using the term in its widest sense), the speaker proceeded to point out that the phenomena which came under observation after an injection of toxin came under observation also after an injection of bacteria. Just as in the first case the injected toxin circulated for a time in the blood of the injected animal, so after the injection of bacteria a similar negative phase probably occurred. It occurred, so far as the speaker's observations had gone, in the blood after an anti-typhoid inoculation, the negative phase being marked by a decline in the normal bactericidal power of the blood. Again, just as in the case of an animal which had been treated with an excess of toxin the blood might—e.g., in the case of animals injected with excessive doses of snake venom—contain toxic in lieu of antitoxic elements at the period when the blood was usually drawn off, so apparently in the case of an animal injected with an excess of a bacterial culture the blood might when drawn off contain substances which were not bactericidal but anti-bactericidal. Such substances were recently described by the speaker[1] as having been found in the specimens of "anti-typhoid sera" which were placed on the market for therapeutic use. Apart from an actual demonstration of the presence of such anti-bactericidal substances, the presence of such substances in "therapeutic sera" had been concluded by the speaker from the phenomena which he had observed in connexion with a sample of anti-plague serum which had been prepared by Dr. Galeotti in Bombay, in the case of certain anti-streptococcic sera, and in the case of a sample of anti-Malta-fever serum prepared by him (Professor Wright). In the former case, where the effects of the anti-plague serum in question were studied by him in association with his colleagues of the Indian Plague Commission, the serum, though when given by itself it did not exert any noticeable toxic symptoms in guinea-pigs, it had the effect of hastening death in guinea-pigs who were at the same time inoculated with plague.

Dr. SIDNEY MARTIN could not agree with all that Professor Wright had said. The whole subject of the specific character of proteids was becoming cleared up. Some years ago it had been said that it was not possible for a proteid substance to be poisonous or to exert any toxic action upon the body. That was exploded now. There was no reason why albuminous substances should not exert a lethal influence on protoplasm, the composition of which was very delicate. Chemical affinity of proteid substances for cells had been brought out very clearly.

Dr. JAMES RITCHIE remarked that the recognition of the poisonous properties of albuminous substances displayed on protoplasm was no doubt important; but to his mind it was still more interesting to note that pathologists were more and more coming to the conclusion that all the fundamental pathological conceptions were biological. He paid a tribute to the late Dr. Walter Myers's work on immunity set up in animals against certain proteid poisons. This opened up a field for the differentiation of the many various kinds of albumin which might be alike in all respects excepting the way in which they reacted to a particular toxin. The want of proportion between the amount of a toxin introduced into an animal and the amount of antitoxin which resulted

[1] THE LANCET, Jan. 12th, 1901.

was a very remarkable fact which needed explanation. He had lately been trying the effects of immunising animals by successive doses of the same size instead of increasing doses. There was an enormous rise in the immunity with each dose. Among the many questions which still remained unsolved was this, Why should the immunity once produced be increased? How was it that the second dose was not neutralised by the antitoxin developed from the first dose?

Mr. T. J. BOKENHAM wished to approach the subject from a clinico-pathological standpoint. How was it that patients were not poisoned by the bacteria met with in such enormous numbers in the intestinal canal? The liver had been suggested as a guard. He had made experiments to see if this applied to the bacillus coli. This bacillus was introduced in quantity and they were not found in the blood on the further side of the liver. But the liver itself was found to be crowded with bacilli. It had been shown that both organic and inorganic poisons were excreted by the bile into the intestines and thus prevented from directly entering the general circulation.

Mr. H. G. PLIMMER wished to draw attention to some of the absurd erroneous purposes and misuses to which antitoxins had been put of late, experimenting with them in different diseases, such as aneurysm. In Italy he had come across several cases of natural immunity to malaria. These persons had allowed themselves to be stung by anopheles which were full of the malaria parasite. There was not sufficient explanation of this natural immunity. Any bacillus injected into an animal's veins would disappear in five or 10 minutes. This applied to anthrax or any other organism.

Dr. W. HUNTER referred to the question of the cells which were concerned in the production of antitoxin. Were they the cells of the body as a whole or were they certain specialised cells? Metchnikoff's theory was the one which he favoured and this implied the action of a special kind of cells. In his (Dr. Hunter's) experiments on hæmolysis he had introduced some of the most powerful hæmolytic bodies into the circulation, but if the spleen had been previously excised they produced no hæmolytic symptoms or effects. This went to show that the phenomenon of hæmolysis at any rate was dependent on the action of cells of a special kind, of a mesoblastic type, and found specially in the spleen.

Professor JOHN MCFADYEAN referred to the necessity for a definition of immunity. Texas fever was now very generally attributed to an animal parasite. Beasts born in a certain district were, it was true, immune, but microscopical examination showed that their blood harboured the offending parasite, nd it would seem in a non-attenuated condition, for blood from these animals could produce the disease very severely when injected into a healthy animal. Some of the small ruminants seemed immune to cattle plague, but the blood of these also contained large quantities of the organism.

Professor SIMS WOODHEAD, in replying, remarked that the malaria parasite was found to be present in the blood of children who appeared to be in perfect health and were immune. Immunity and antitoxin production appeared to go on side by side, but he agreed with Dr. Ritchie in believing that they were not identical.

MEDICAL SOCIETY OF LONDON.

The Structure of the Vermiform Appendix and its Homologue in the Lower Animals.

A MEETING of this society was held on March 11th, Mr. JOHN H. MORGAN, the President, being in the chair.

Dr. RICHARD J. A. BERRY (Edinburgh) read a paper entitled the True Cæcal Apex, being an attempt to prove that the vermiform appendix was not a vestigial structure, accompanied by a lantern and microscopic demonstration. He commenced by describing the four different types of cæcum and appendix met with in man and then gave an account of the structure of the cæcum in different members of the animal kingdom—viz., the rabbit, cat, pigeon, skate, frog, goose, fish-eagle, Javan adjutant, fowl, kangaroo, sloth, pig, sheep, mouse, beaver, squirrel, hyæna, dog, marmoset, monkey, ape, and others. In man the vermiform appendix represented the true apex of the cæcum, but as there were but few vertebrates which presented a vermiform appendix the apex of the cæcum (the equivalent of the appendix vermiformis in the lower animals) was examined histologically to see what, if any, analogies and homologies existed between them. The various facts observed were described in some detail. The theories to be based upon them would, he said, be considered on a future occasion. As regards the animals examined, with the exception of the cold-blooded animals, the skate and the frog, the marsupials and sloths (animals which were notoriously difficult of classification), the hedgehog (a hibernating animal without a cæcum), and the Patagonian cavy, the cæca of all were characterised by large amounts of lymphoid tissue. The lymphoid tissue was either specially aggregated together in distinct and definite masses (and more especially was this the case when the cæca were short, as in the cat and the pigeon), or else it was diffused throughout the total length of the cæcum, particularly when this structure was long, as in the domestic fowl, the pig, and the sheep. In all instances the lymphoid tissue tended to be better marked at the cæcal apex, or at all events very near the cæcal apex, as in the mouse and the rat. In the majority of the animals examined the amount of lymphoid tissue contained in the cæcum was largely in excess of that contained in other parts of the large intestine. The line of demarcation between the two was in many instances, such as in the pigeon the rabbit, the cat, the mouse, the rat, the dog, the striped hyæna, &c., most abruptly marked. It had been proved beyond doubt that the characteristic feature of the normal human appendix was lymphoid tissue; and the facts adduced pointed to the conclusion that the histological homologue of the human appendix was to be found in the cæcum of the lower animals. The precise seat of the lymphoid tissue in the cæcum varied somewhat in the different animals. In the pigeon it occupied the entire cæcal wall; in the mouse and the rat the lateral wall of the cæcum near its apex; in the majority of the animals examined it occupied the cæcal apex itself; whilst in the higher vertebrates it was confined to the vermiform appendix. The author came to the following conclusions. 1. Lymphoid tissue was the characteristic feature of the cæcal apex. The vermiform appendix of man was therefore represented in the vertebrate kingdom by a mass of lymphoid tissue situated most frequently at the cæcal apex. 2. As the vertebral scale was ascended this lymphoid tissue tended to be collected together into a specially differentiated portion of the intestinal canal—the vermiform appendix. 3. The vermiform appendix of man was not, therefore, a vestigial structure but a specialised part of the alimentary canal.

The PRESIDENT congratulated Dr. Berry on his paper. The late Professor Rolleston had pointed out that the presence of an appendix was confined to the higher apes and the wombat. He thought that Dr. Berry had established his point.

Mr. C. B. LOCKWOOD wished to express his appreciation of the beautiful specimens exhibited. It was difficult to realise the amount of labour involved. He thought that Dr. Berry's researches had an immediate bearing on clinical medicine and surgery. Dr. Berry had proved his position. The appendix was not a retrograding structure. It continued to grow and develop after birth. He had removed this structure from a child, aged four years, and from a man, aged 70 years, and he had found lymphoid follicles quite as well developed in the latter as in the former. Dr. Berry's specimens also revealed another important practical fact to which he (Mr. Lockwood) wished to direct attention. They demonstrated the existence of a basilar lymph channel which collected the lymph from the lymphoid tissue and communicated with the lymphatics of the mesocolon, the lymphatics of the peritoneum, and elsewhere. It was along this route that septic matter was absorbed from inflamed appendices. Numerous septic organisms had been demonstrated within the appendix under these circumstances, which explained the serious train of symptoms which arose when an inflamed appendix was left, although the mucosa might be entire on examination. There was certainly one type of disease which consisted of lymphangitis of the appendix and another of lymphadenitis of the appendix. He was inclined to locate the lymphoid tissue in the mucosa rather than in the submucosa.

Dr. BERRY, in reply, said that he believed the lymphoid tissue to be localised chiefly in the submucosa, though it sometimes extended to the mucosa also. The diet of the animals was a most important subject, for he felt sure that the lymphoid tissue had a definite relation to the food of an animal. For instance, in the carnivora

the cæcum was short, in the herbivora it was long, while in omnivorous animals the cæcum was intermediate in size, and it was more particularly in the latter that lymphoid tissue was abundant. He had ligatured the appendix in several rabbits and allowed them to live for varying periods of time —two days, four days, eight days, and one month. In every case he found that leucocytes had wandered into the cavity of the appendix.

CLINICAL SOCIETY OF LONDON.

The Epidemic of Enteric Fever among the Troops in South Africa.

A MEETING of this society was held on March 8th, Sir R. DOUGLAS POWELL, Bart., the President, being in the chair.

Dr. H. H. TOOTH opened a discussion on the Epidemic of Enteric Fever among the Troops in South Africa. His paper is printed in full on p. 769.

Surgeon-General J. JAMESON (Director-General of the Royal Army Medical Department) expressed his great interest in Dr. Tooth's remarks. Enteric fever had always been a bugbear in South Africa. Instructions were drawn up early in the war and he did not think, looking back, that there had been anything to add to these. Some years ago the post of sanitary officer was abolished from the army. This was perhaps unfortunate, for the principal medical officer of a division, to whom the duties of sanitary officer were allotted, was fully occupied with the care of the sick and other duties. He (Surgeon-General Jameson) had, however, at the very commencement of this war appointed Captain M. L. Hughes, R.A.M.C., in that capacity and had equipped him with a bacteriological and chemical outfit and sent him out by the same ship as Sir Redvers Buller. Unfortunately, this gentleman was killed in action early in the war, and this he regarded as a national misfortune. No doubt there were great difficulties in dealing with these epidemics, and perhaps the greatest of these was the personal equation of the soldier who did not hesitate to drink when he was thirsty without troubling about the sanitary condition of the water. An admirable method of dealing with the latrines was now in vogue. In all standing camps a trough containing milk of lime was provided into which the excreta were received and removed to a distance.

Professor A. E. WRIGHT (Netley) wished to refer to the subject of inoculation but he did not propose to deal with the whole question. He agreed with Dr. Tooth that excessive reaction meant greater need for protection; but it also meant excessive dosage, and he believed that small doses were better. They must assume that a person after an attack of enteric fever became more immune, and their endeavour should be to make the blood of a patient like the blood after an attack of the disease as tested by Widal's reaction. But, unfortunately, this reaction was not always obtainable after an attack of the disease. Special methods were therefore necessary to test the blood in such circumstances and he had made investigations into the bactericidal power of the patient's blood. Remarkable facts had resulted from these experiments. Some patients came out of an attack of enteric fever with the bactericidal power of their blood actually diminished. The liability to relapses was another question of importance. A small bactericidal power generally meant greater tendency to relapse, and the case of a man was referred to who had two inoculations and two definite attacks of the disease in the course of two years. The object should be to make the blood like that of a man who had come out well after an attack of enteric fever, and he believed that this was largely a question of dose in relation to the particular individual to be inoculated. Professor Wright then referred to the various statistics bearing on inoculation. There were not, he said, at present a very great number. First, in the Maidstone epidemic there were 84 warders and attendants at the lunatic asylum who were inoculated and among these there were no cases, whereas of the 120 who were not inoculated four were attacked. In India, in 1898–99, he had inoculated 4502 soldiers under very difficult circumstances, standardising his typhoid vaccine in hotels and trains. He was therefore not satisfied with the quality of the vaccine then employed; nevertheless, only 0·98 per cent. of the inoculated got enteric fever as against 2·5 per cent. among those not inoculated in the same garrison and regiments. In South Africa, among the Ladysmith garrison,[1] out of 1705 persons inoculated only 2 per cent. were attacked, whereas of 10,529 not inoculated 14 per cent. were attacked. The statistics of the officers appeared at first to contradict these figures, for out of 44 inoculated there were two deaths, and among 171 non-inoculated there were only five deaths. But further inquiry showed that there were really no deaths among the former, and 12 deaths among the latter, and consequently the percentages were the same among the officers as among the men. An epidemic in one of the Hussar regiments[2] was referred to in which among 360 inoculated men there only occurred two cases and no deaths, whereas among 160 non-inoculated there were 11 cases and six deaths. Then there were the figures from the Scottish Hospital; in the first section of the hospital staff 61 were doubly inoculated and among them there were no cases; in the second section there were 82 of whom 35 were inoculated and there were no cases, and one not inoculated contracted enteric fever. Out of 46 medical men and orderlies nearly all of whom were inoculated three uninoculated got enteric fever and one died, two had been inoculated only once and of these one got enteric fever and died. A large number of altogether reliable statistics bearing on this question were, however, still wanting. Turning to the question of methods, a person ought certainly to be inoculated twice—once did not give efficient protection. It was best to begin with a small dose and there should be an interval between the injections. This might be followed by a larger and stronger injection. Finally, there should be an interval after the second injection before proceeding to the seat of war. But how was it possible to carry out all these conditions in the presence of a big campaign suddenly thrust upon them like the present? He had therefore been obliged to content himself with one large dose. The inoculations had often been done on board ship on the way to South Africa by various surgeons, some of whom were enthusiasts in the cause of enteric inoculation, but many were not.

Sir DYCE DUCKWORTH congratulated Professor Wright upon his researches, the value of which was undoubtedly very considerable. He thought that the results of typhoid inoculation were most encouraging. In his opinion nurses, medical men, and others liable to be exposed to the infection ought all to be protected in this way. The inoculation should certainly be done twice and all statistics in which only one inoculation was performed should be kept carefully apart from the double inoculations.

Major W. G. MACPHERSON, R.A.M.C., endorsed Dr. Tooth's statement that the Bloemfontein epidemic was a direct result of the Modder river outbreak. All experience went to show that enteric fever attacked fixed camps rather than moving armies. An equivalent of the water-carriage system of drainage had been adopted in some of the American armies in the Cuban campaign. The excreta were received into troughs containing quicklime and water. The American troughs were not emptied into a drain but by means of a pump. Sand-storms and flies propagated enteric fever but were very difficult to combat. Places where flies bred must be destroyed. It was found that food suspended in the neighbourhood of the American latrines became covered with quicklime brought by the flies. Open shallow trenches were to be condemned; they should be 10½ feet deep. The deep trench system was better than the bucket system. Bad teeth, he believed, led to a predisposition to enteric fever. Referring to Professor Wright's statistics of enteric fever in 1899, the case mortality among the inoculated and uninoculated was the same. Reference was made to the case mortality in No. 8 Military Hospital where 2500 cases had been admitted between April and January. The case mortality was 9·2 per cent. In Bloemfontein hospital with 258 cases it had been 8·1 per cent. These figures did not differ very widely from the case mortality in civil hospitals—viz., 7·1 per cent.; and if all cases of simple continued fever had been included the mortality would probably have been identical. In the army it was always the practice to regard cases of "simple continued fever" as distinct from enteric fever and they were never included under that heading.

The discussion was then adjourned.

OBSTETRICAL SOCIETY OF LONDON.

Midwifery a Hundred Years Ago.—Exhibition of Specimens.

A MEETING of this society was held at 20, Hanover-square, W., on March 6th, Dr. PETER HORROCKS, the President, being in the chair.

The PRESIDENT delivered his Inaugural Address, taking as his subject the Condition of the Science and Art of Midwifery and Diseases of Women a Hundred Years ago and tracing its progress up to the present time. The classification of labour into (1) natural, (2) laborious, and (3) preternatural by Smellie with the addition of (4) complex added by Denman, was quoted. Natural labour was considered a century ago a most dangerous and difficult procedure, requiring the very highest skill on the part of the accoucheur or midwife. And although the practice of meddlesome midwifery, such as dilating the vaginal orifice or os uteri by means of the fingers, was vigorously condemned, yet it was considered perfectly proper and advisable to prevent rupture of the perineum in a too precipitate labour by forcible resistance to the head when distending the perineum, and if the placenta was not soon delivered by the natural forces traction on the umbilical cord was advised. In preternatural labours two instruments were in use—namely, the vectis or lever, championed by Denman, and the forceps, extolled by Osborn. When craniotomy was needed the head was perforated and the child was left for from 24 to 36 hours in order that putrefaction might supervene and so soften the bones of the head and allow a more easy breaking up by means of the crotchet. Cæsarean section was always fatal to the mother and was rarely, if ever, performed, the patients dying from septic poisoning unless they were carried off by shock or hæmorrhage. Symphysiotomy was condemned as an unjustifiable operation. Post-partum hæmorrhage was very common and was treated by raising the patient up suddenly, in order to make her faint, or by applying cold to the abdomen. Fever was so common after labour that pregnancy itself was defined as a "certain inflammatory disposition of the body," and support was given to this view by the alleged "fizzy" condition of the blood and the "buffy coat" and the "more frequent pulse." Various forms of fever were described, and it was shown that puerperal fever was very common although called by different names. Its treatment was chiefly by bleeding. Convulsions were regarded as due to "morbid irritability," albuminuria being at that time unknown. Abortion and threatened abortion were treated by repeated bleedings. Extra-uterine fœtation was treated on the expectant plan. The bowels were to be kept open, poultices were to be applied, and any abscess forming was to be laid open. Operative procedures were not recommended, as they were nearly always fatal. There was an entire absence of all reference to even ordinary cleanliness on the part of the attendants or of the instruments. The paucity of remarks on diseases of women was pointed out. They were included in books on midwifery and generally occupied about a fifth of the space. Ovarian tumours were treated by tapping when they got so large as to cause distress. Sometimes stimulating drugs were injected into them to try to cure them, or attempts were made to get them to adhere to the abdominal wall. But as a rule they proved fatal sooner or later, for their removal was obviously not even entertained. Cancer of the uterus was treated by palliatives. Fibroids were called "tubercles" and were never interfered with unless they became polypoid. Fallopian tube diseases were practically unknown. The progress made during the century was then pointed out, certain important events being specially mentioned, such as the introduction of chloroform by Simpson, the use of the cephalotribe and the craniotomy forceps, the abandonment of venesection, and the discovery that albuminuria was present in nearly all cases of eclampsia. Semmelweiss's discovery that attendance on post-mortem examinations was highly dangerous for those who were in attendance on lying-in women and Credé's method of delivering the placenta were further instances. The commencement of the antiseptic and aseptic era by Pasteur and Lister was then described and the gradual evolution of this idea by eliminating all pathogenic germs from the attendants' hands, as well as from the patient, the clothing, the skin, the sutures, the needle, the instruments, and the sponges. The improvement in the management of natural labour owing to the knowledge of asepsis was described and it was pointed out that puerperal fever had been eliminated from lying-in hospitals, not by routine douching either of vagina or uterus, which was unnecessary and not devoid of risk, but by a scrupulous observance of the rules of asepsis. Natural labour was described as a physiological act, which considerably over 90 per cent. of women could accomplish safely if left alone. The ease with which Cæsarean section and symphysiotomy could be performed with safety to mother and child was noted, and it was pointed out how nowadays rupture of the uterus was often recovered from by simply packing with antiseptic gauze. This was due probably to the fact that the accoucheur in his previous manipulations had done everything aseptically. The low mortality in operations for extra-uterine fœtation was noted. It was also pointed out that length of incision in ovariotomy and other abdominal sections did not in the least matter nowadays, although it did in the time of Sir Spencer Wells. The great advance in the knowledge of the cause, symptoms, pathology, and treatment of diseases of the Fallopian tubes was shown. In addition to the vast improvements made by the evolution of asepsis it was shown that the transfusion of blood was not only of no benefit but was positively injurious, and yet it was now possible to save patients who were in danger of death from excessive loss of blood by the simple plan of replacing it by an equal amount of fluid, such as water. The improved status of obstetricians was alluded to and a hope was expressed that in the near future great advances might be made, more especially as regards that scourge of mankind and especially of women—namely, cancer—for which at present there was no cure, the knife offering the best chance for escape and that often only for a time.

Dr. ROBERT BOXALL showed a specimen of a Uterus with Large Cystic Fibroid and Subperitoneal Fibroid Nodules, Cystic Ovaries, and a Small Carcinomatous Nodule in the Fimbriated End of the Right Fallopian Tube. This specimen, comprising the greater part of the uterus with its appendages, was removed by operation from an unmarried woman, aged 48 years. When the abdomen was opened the cyst was tapped and after both sets of ovarian vessels had been tied the patient became suddenly collapsed. It was then found that copious hæmorrhage was taking place into the cyst from a venous sinus situated on its inner wall large enough to admit the index finger. This bleeding was controlled temporarily by enlarging the opening into the cyst and turning it inside out. After the operation was completed saline injections were given by the rectum and the patient rallied well.

Dr. ARNOLD W. W. LEA showed a specimen of Sarcoma of the Uterus with Microscopical Sections from a patient, aged 62 years, whose menopause had occurred at the age of 50 years. She had had uterine hæmorrhage and pelvic pain for four months. She died from exhaustion and septic poisoning. Microscopically the growth in the uterus was composed of large round cells with deeply-stained nuclei. The stroma was scanty but contained large blood-vessels. The growth was evidently interstitial in origin, the mucosa being smooth and atrophic.—Dr. C. J. CULLINGWORTH and Mr. ALBAN DORAN discussed the case.—Dr. LEA replied.

Dr. WILLIAM DUNCAN showed a specimen of Multiple Myxomatous Polypi from the Cervix Uteri. The patient was a widow, aged 57 years, who was admitted into the Middlesex Hospital on May 16th, 1900. The growth was composed of between 20 and 30 polypi of various sizes attached to a single base, the largest of which was of the size of a walnut, the others being from one inch to one and a half inches long and one-third of an inch wide. The patient made an uninterrupted recovery.

Dr. DUNCAN also showed two specimens of Uterine Fibroids removed from his last two cases of 100 consecutive intra-peritoneal hysterectomies for fibroids. His mortality was four, his last 53 operations having had no mortality. He attributed his good results to his plan of injecting three minims of liquor strychniæ thrice daily for several days before and after operation, thus diminishing the danger from heart failure and shock, which were the great dangers after hysterectomy.—Dr. AUST LAWRENCE made some remarks.

Dr. W. F. VICTOR BONNEY showed a specimen of Uterus Bicornis Unicollis which was removed from a Hydrocephalic Fœtus presenting besides a double Hare Lip and Absence of the Hard and Soft Palates. There was also a deficiency of

the septum ventriculorum and the aorta came from the right ventricle. The uterus consisted of two corpora terminating in a single cervix. The corpora were distinct at their upper parts, but united below, where their cavities were separated as low as the internal os by a median septum. The recto-uterine pouch of peritoneum was single. The ovaries and tubes were perfect, each coming off from its corresponding cornu. The vagina was single, but presented a well-marked median ridge on its anterior aspect.

HARVEIAN SOCIETY OF LONDON.

Gonorrhœal Iritis.—Exhibition of Cases and Specimens

A MEETING of this society was held on March 7th, Dr. D. B. LEES, the President, being in the chair.

Mr. JOHN GRIFFITH read a paper on Gonorrhœal Iritis. He pointed out that gonorrhœa was a common cause of iritis and was, in fact, a more common cause than syphilis. Not only was it a complication, it was also a sequel of gonorrhœa. Cases occurring at a remote period after the attack were overlooked as regards their causation and being often recurrent were regarded as rheumatic. It was his experience that recurrent iritis was due to gonorrhœa, both this and the rheumatic troubles being subsequent to the attacks of the urethritis. Some instances of recurrent iritis occurred without any history of any rheumatic affection. He disagreed with the view of Mr. Treacher Collins that "syphilis is by far the most frequent constitutional disease to give rise to iritis." Syphilitic iritis was said not to recur and in the recurrent cases there was probably a past attack of gonorrhœa to which the recurrence was due. In his experience cases of recurrent iritis in syphilitic subjects had been associated with rheumatism and a history of urethritis. He gave details of illustrative cases, one of which was that of iritis in one eye, the result of gonorrhœal ophthalmia in the other, in a patient who had never had urethritis. In conclusion, he expressed the view that gonorrhœa was as constitutional a disease as syphilis, that iritis was more often caused by gonorrhœa than by syphilis, and that it often occurred at a period remote from the date of inoculation.—Dr. SYDNEY STEPHENSON said that it was an undoubted fact that iritis or cyclitis might occur many years after the primary lesion of constitutional syphilis. He had once observed an interval of 19 years. Iritis might also be met with long after an attack of malarial fever. From analogy, therefore, he saw no *primâ facie* reason for disbelieving in Mr. Griffith's theory of a post-gonorrhœal iritis.

Dr. WILFRED HARRIS showed a case of Fifth Nerve Paralysis in a woman, 43 years of age, who three years before had fallen, striking the right side of her forehead severely, and had lost consciousness for a few moments. Four and a half months later severe pain began in the forehead at the site of the blow and spread over the right cheek, for which she had most of her teeth extracted on the right side, but derived no benefit. When first seen, two and a half years ago, there was nothing found on examination but some slight numbness of the right side of the face and she also complained of diplopia. Soon after this she was ill for six weeks, suffering from recurrent convulsions, five and six a day, with vomiting and loss of consciousness. She was next seen in January last, when almost complete paralysis of the right fifth nerve was found with the usual distribution of anæsthesia on the scalp, face, and inside of the cheek as far back as the anterior pillar of the fauces and the junction of the hard and soft palates. There was complete loss of taste on the anterior portion of the tongue, but on the back of the tongue on the right side she could just perceive bitter flavours and the electrical sensation to galvanism, and this had markedly improved under treatment. Motor paralysis also was marked, but slight contraction of the right masseter could be felt. She complained also of some loss of sight in the right eye, both discs being slightly pale, though vision was normal in the left eye. The right pupil was slightly contracted and scarcely reacted to light, giving only the smallest movement when exposed to bright diffused daylight, though the left pupil reacted perfectly both directly and consensually. There was no ptosis and it seemed a matter of doubt whether the condition was one of sympathetic paralysis of the pupil or whether it was a case of uni-ocular Argyll-Robertson pupil. Except for the very doubtful optic atrophy there was no other sign of tabes dorsalis and there was no history suggestive of syphilis, as would be expected if Argyll-Robertson pupil existed. The severe trigeminal pain still persisted and Dr. Harris was of opinion that the condition was due to a lesion of the Gasserian ganglion, possibly pachymeningitis, the result of the fall on the forehead, which might have caused a slight fracture of the base. She was being treated electrically four times a week with strong constant current to the forehead and the back of the ear, which always relieved the pain for several hours or even a day or two. If permanent improvement did not result the question of the advisability of removal of the Gasserian ganglion might have to be considered.—Mr. JACKSON CLARKE said that fracture of the base of the skull frequently passed near the apex of the petrous bone and when this was the case the Gasserian ganglion might subsequently become involved in inflammatory tissue. Since Dr. Harris's patient was improving he would not advise operation at present. He (Mr. Clarke) had successfully excised the ganglion by the extra-cranial route in a case of severe tic-douleureux. This distressing affection justified the operation, serious as it was. If he should be called upon to remove the ganglion again he would do so by the intra-cranial route.

Dr. HARRIS also showed a case of Syringomyelia in a woman, aged 42 years, who had suffered from infantile paralysis when three years old, affecting the left arm and leg, the recent wasting and pain due to the syringomyelia being limited to the left arm, while partial left hemianæsthesia both to touch and pain had developed under observation, as also similar sensory loss on the right hand and lower forearm.

Dr. DOUGLAS DREW exhibited two specimens of Carcinoma of the Rectum, one of which was associated with intussusception, which he had successfully removed. The first specimen, which was preserved in the museum of the Royal College of Surgeons of England, showed a nodular growth surrounding five-sixths of the circumference of the rectum and forming the apex of the invagination which had been removed with it. The patient from whom the specimen was removed had a month previously been operated upon for cystic disease of both ovaries. The growth and intussusception were not discovered until after the operation, when great difficulty was experienced in relieving the bowels. The growth reached to within two and a half inches of the anus and the invaginated portion measured about three inches in length. The mass was removed by dividing the anus and rectal wall posteriorly as far as the coccyx, which allowed the growth to be drawn outside. The layers of the invaginated portion were sutured together with silkworm-gut, which transfixed them, and the mass was cut away with scissors by degrees as the sutures were tied. The patient made an uneventful recovery and when seen six months after the operation was in good health. Dr. Drew attributed the successful result to the method of removal employed, which insured the security of all vessels (some of which were of unusual size) before their division—a point of vital importance owing to the enfeebled condition of the patient. Attention was directed to the extreme rarity of the condition, the tendency of malignant disease being to become fixed to surrounding structures and to thus render the occurrence of invagination impossible. On the other hand, invagination was not uncommonly associated with pedunculated growths of the bowel, the explanation being that the tumour dragged on the wall of the bowel and the peristaltic movement gripped it and drove it onwards. The other specimen exhibited by Dr. Drew showed the lower five inches of the rectum with the anus and posterior vaginal wall which had been removed by the trans-sacral route from a woman aged 30 years. Dr. Drew called attention to the advantage of performing a preliminary colotomy in those cases in which it was necessary to remove the anus.

Mr. JACKSON CLARKE showed a man, aged 58 years, from whom he had removed the Rectum for Cancer by the Trans-sacral Method nearly two years ago. The patient was now in good health and the bowel and the sphincter had their normal functions. The first time that he (Mr. Clarke) had done this operation, now some five years ago, he had done a preliminary colotomy which he repaired by a plastic operation before the patient left the hospital. This patient he traced for three years and there had been no return of the disease. Latterly he had dispensed with the preliminary operation.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Specimens.—Stenosis of the Small Intestine as a Sequel of Strangulated Hernia.—Myasthenia Gravis.—Method of Determining the Influence of Drugs upon the Liver.

A MEETING of this society was held on March 6th, Mr. ALEXANDER MILLER, the President, being in the chair.

Dr. ALEXIS THOMSON showed about a pint of Loose Bodies (hyaline cartilage) from the knee of a woman, aged 36 years. She had suffered more or less for 15 years from the joint affection, but it was only during the last six months that she was crippled and unable to walk.

Dr. DAWSON TURNER exhibited a Roentgen photograph of Renal Calculi from a patient operated upon by Professor Annandale. In order to get a successful photograph of such a case the calculi must be dense and large; there must be a short exposure, otherwise the plate becomes fogged (the exposure was two minutes in this case); the bowels must be thoroughly emptied and the movements of the abdominal walls must be limited.

Dr. ALEXANDER BRUCE (for Dr. AFFLECK) exhibited a greatly Dilated Heart from a woman, aged 69 years, who had been in the Incurable Hospital for seven years. She had been tapped 188 times and 53,494 ounces of fluid had been removed from the abdomen, or a weight equal to one and a half tons. There had never been any albuminuria or any dropsy other than ascites. The liver was pulsating and enlarged. The largest amount of fluid removed at once was 414 ounces.

Dr. CHALMERS WATSON showed a series of microscopic preparations illustrating the Primary Importance of Vascular Disease in the Etiology of Chronic Nervous Affections (Comparative).

Dr. ALEXIS THOMSON read a paper on Stenosis of the Small Intestine as a Sequel of Strangulated Hernia. He stated that almost any damage to the intestine terminated in recovery except gangrene of the bowel. Owing to the mechanical constriction at the neck of the hernial sac the bowel became grooved or furrowed. This took place commonly at both ends of the loop of intestine in the sac. This furrow might be only on one side or it might be all round the bowel. As a rule when the bowel was liberated and stroked these furrows disappeared. Sometimes, however, they persisted and if so the patient was not relieved of the obstruction and might die from it. Again, these furrows might afterwards become the site of fibrous stricture, rendering the patient the subject of chronic intestinal obstruction. Two such cases were described. In the first case the patient was a boy, aged two years, who had symptoms of obstruction on the left side together with an undescended testicle. Dr. Stirling of Perth performed herniotomy and noted the presence of two well-marked grooves Three days after the operation the symptoms still persisted though the abdomen was not distended. Dr. Thomson, who saw the boy, then decided that the obstruction was still present. The abdomen was opened and the bowel was found lying close to the incision with well-marked grooves on it. The bowel was greatly distended above this furrow and collapsed below it. The site of the furrows was at the highest part of the jejunum. The bowel was pulled out of the wound and an artificial anus was made. After this, however, the child suffered from malnutrition; when porridge was given it almost immediately escaped from the artificial anus. Another operation was performed and the ends of the bowel were joined, and the child made a perfect recovery. Nine inches of the bowel were resected. A microscopic examination of the bowel at the seat of constriction showed that it was the seat of leucocytosis and escape of red corpuscles, and was beyond the chance of recovery. The second case was that of a Left Inguinal Hernia strangulated for three days. There were two well-marked grooves and the bowel was considered viable, though some peritonitis was present. After the operation the patient remained well for three weeks, when symptoms of chronic obstruction ensued. In 12 weeks he had become greatly emaciated and the abdomen enormously distended, exhibiting the ladder pattern. The diagnosis was obstruction due to grooving. In the first instance an artificial anus was made and 16 days later the bowel was resected, being greatly dilated above the seat of constriction. The microscope showed that the mucosa had disappeared at the seat of stricture.—Dr. F. M. CAIRD said that the condition was exceedingly rare. One case he recalled, however, was in a strangulated femoral hernia. Six months after operation the patient died and it was found that the septum which had formed was very strong and the mucosa greatly destroyed. The death of the bowel took place from within outwards.

Dr. EDWIN BRAMWELL read a paper on Myasthenia Gravis. He considered that the disease was one with which every practitioner should be acquainted, since it was often mistaken for hysteria, since it was often fatal, and since, in some cases at least, a fatal issue could probably be averted by appropriate treatment. He had examined nine cases of the disease. He described the case of an unmarried female, aged 23 years, who had previously enjoyed good health. Ten weeks before he saw her, without apparent exciting cause, she had gradually developed difficulty in speaking, swallowing, and chewing, weakness of the ocular muscles, of the palate, and of the neck and arms. In the morning she was usually free from symptoms, but as the day went on weakness in these various muscles developed. If she continued to use any of the above-mentioned muscles a state of temporary paresis ensued, associated with a feeling of fatigue. The myasthenic reaction was demonstrated in the right biceps muscle. The muscular weakness was unaccompanied by atrophy; the deep reflexes were brisk; the plantar reflex was of the flexor type; the sphincters were unaffected, and there was no objective disturbance of sensation and no affection of the special senses. The absence of any weakness in the legs and of ptosis was an unusual feature of the case. Dr. Bramwell considered the term "myasthenic state" as suitable to denote the peculiar condition of the muscles met with in this disease, whereby they become readily fatigued by voluntary effort. The seat of the lesion was most probably in the motor neurons, and clinical evidence seemed to point to the lower neuron as being at least the chief seat of the affection. Although Déjerine and Thomas had recently described a case in which definite post-mortem findings were present it remained to be seen whether future observations would show that these changes were constant. Attention should be directed to the following points in making a diagnosis: (1) the presence of muscular weakness which was often slight in degree and was unassociated with atrophy; (2) the facility with which the muscles became exhausted both by voluntary effort (myasthenic state) and by faradaism (myasthenic reaction); and (3) the absence of sensory symptoms apart from the fatigue of exhaustion, of sphincter trouble, and of mental disturbance. The prognosis was a matter of great uncertainty. Most cases were characterised by temporary improvements and relapses. Of 60 cases collected by Dr. Harry Campbell and himself 23 had ended fatally. In the majority of fatal cases death had been due to an attack of dyspnœa. Since muscular exertion and mental excitement increased the severity of the symptoms, they must both so far as possible be avoided. All solid food should be minced in order to spare the muscles of mastication and to avoid, so far as possible, the risk of choking. Dr. Bramwell was of opinion that in a severe case, where there was great muscular weakness and the patient's life was in danger, inhalations of oxygen and transfusion with saline fluid might prove of value.

Dr. NOEL PATON and Dr. EASON communicated a paper on a Method of Determining the Influence of Drugs upon the Liver. It had for long been understood that certain drugs diminished the activity of the chemical changes in the body. So far, however, no attempt had been made to determine which tissues or organs were specially affected. It appeared to Dr. Paton and Dr. Eason that some indication of the structures acted upon and of the degree of interference with their functions might be gained by a study of the extent to which the waste nitrogen of the body was elaborated into urea, since it was in the liver that this formation of urea was chiefly carried on. The experiments were made upon dogs which were put on a fixed diet until nitrogenous equilibrium was reached. The dogs were subjected to the agent and the urine was carefully collected and examined. The results were as follows: (1) morphine had no action in the building up of nitrogen into urea; (2) sulphonal had most marked effects, diminishing the elaboration of nitrogen into urea; (3) alcohol had a marked effect on the liver, increasing the uric acid; it reduced the average percentage of nitrogen excreted as urea from 79·5 to 73·0; and (4) coal

gas had a great effect in diminishing the processes of oxidation in the body due to the carbon monoxide present: it diminished the proportion of nitrogen excreted as urea and of sulphur in the oxidised form but did not alter the proportion of phosphorus to nitrogen.

BRITISH ORTHOPÆDIC SOCIETY.—The annual general meeting of this society was held at the City Orthopædic Hospital, Hatton-garden, E.C., on Feb. 16th, Mr. Noble Smith being in the chair.—The reports of the honorary secretaries and treasurers showed that the society was in a sound condition. The three years' term of the town honorary secretary (Mr. Muirhead Little) having expired a hearty vote of thanks for his very valuable services was passed unanimously. Mr. Chisholm Williams and Dr. A. F. Blagg (Bristol) were elected to act as the honorary secretaries. The following members were elected to the council: Mr. W. Armstrong, Mr. W. E. Bennett, Mr. Jackson Clarke, Dr. Percy Lewis, Mr. G. P. Newbolt, Mr. John Poland, Mr. H. A. Reeves, and Mr. Noble Smith. Mr. C. B. Keetley was re-elected treasurer.—The ordinary meeting was then held — Mr. Muirhead Little showed a case of Kyphosis with probably Rheumatic Complications. The patient, a young man, had a slight slip from a horizontal bar whilst practising gymnastics and ever since then had had a grating noise like loud crepitations whenever the right scapula was moved. The noise could be heard at a distance of several feet when the patient was stripped. There was neither pain nor impairment of either strength or motion.—Mr. Noble Smith, Mr. Jackson Clarke, and Mr. John Ewens commented on the case.—Mr. Muirhead Little also showed a case of Injury to the Upper Epiphysis of the Humerus in a boy who had been shown before the society on a previous occasion. With a view of remedying the deformity he had operated by dividing the humerus below the insertion of the deltoid and rotating it out about 30°. The hand and arm which had been quite useless could now be used fairly freely and the patient could rotate his arm with more or less ease.—Mr. Noble Smith read notes of a case of Separation of the Epiphyseal Head of the Femur in a girl, aged 17 years, who consulted him in 1885, the case being one of the earliest recorded of this particular injury.—Mr. John Poland opened a discussion on the Results of Injuries and Diseases of the Epiphyses and their Treatment.—Mr. Jackson Clarke, Mr. Muirhead Little, Mr. Ewens, and Mr. Chisholm Williams took part in the discussion.

MANCHESTER THERAPEUTICAL SOCIETY.—At a meeting of this society held on Feb. 27th Dr. J. Dreschfeld, the President, opened a discussion on the Use of Urotropine in Urinary Affections. He had obtained the most satisfactory results from the use of this drug in the pyuria of cystitis. It answered well in cystitis due to hypertrophy of the prostate, gonorrhœa, gout, after typhoid fever, and in arsenical poisoning. It was also useful in pyelitis, four of six of such cases doing well with urotropine. One of these cases was undoubtedly tuberculous and two were calculous in origin. The two unfavourable results were in tuberculous cases. As a solvent for uric acid its value was doubtful, though good resulted in two cases after its use which had resisted other treatment. In one case of gouty sciatica the drug seemed to give much relief. The mode of administration was to give the drug in from 10- to 15-grain doses three times a day in powder form placed on the tongue and followed by a drink of water. This dose had been continued for weeks in some cases. Large doses sometimes caused tenesmus and pain in the bladder, and some patients felt sick and depressed when taking it. Bismuth with the powder tended to prevent the nausea.—Dr. Dixon Mann had used the drug with beneficial results in anomalous cases of cystitis with no definite cause. He found it quite useless in a case of idiopathic bacteriuria — Mr. W. P. Montgomery confirmed some of the above results and thought the drug most useful in cystitis due to enlargement of the prostate, especially when the urine was alkaline.—Dr. R. T. Williamson and Dr. R. B. Wild also spoke favourably of the drug, the former having had good results with it in a case of compression myelitis with paralysis of the bladder.—Dr. Wild read a paper summarising the Effects Produced by Injections of "Coley's Fluid" in eight cases of Malignant Disease, in no one of which was any permanent benefit produced.

MIDLAND MEDICAL SOCIETY.—The sixth ordinary meeting of this society was held on Feb. 27th at the Birmingham Medical Institute, Mr. Jordan Lloyd, the President, being in the chair.—Mr. L. P. Gamgee showed a man, aged 32 years, who, in October, 1900, suffered from Acute Pneumonia. During his illness the right leg and afterwards the left leg became greatly swollen and œdematous. He now had œdema of both legs with very marked dilatation of the superficial epigastric and circumflex iliac veins on the right side, and of the superficial circumflex iliac veins on the left side, the left superficial epigastric vein being thrombosed. The condition was apparently due to double femoral thrombosis.—Dr. J. W. Russell showed a man, aged 26 years, who had suffered from "Blood-poisoning" in June, 1900. No definite information could be obtained respecting this attack except that it was accompanied by pain and tenderness over the right femoral vein. Four weeks later similar symptoms appeared on the opposite side. There were now a solid œdema of both legs and dilatation of the superficial epigastric veins on both sides, most marked on the right. The right superficial circumflex iliac vein was also dilated.—Mr. John W. Taylor showed a specimen of Calcified Fibroma of the Ovary removed from a young married woman, aged 26 years. Mr. Taylor commented on the rarity of fibroid tumour of the ovary and on the extreme rarity of one which had undergone such calcareous or (possibly) bony transformation. The specimen was as hard as stone and undoubtedly caused occasional contusions of bowel on unguarded movements of the patient.—Dr. A. Douglas Heath read a paper on Dermatitis from Common Irritants, and Dr. T. Sydney Short read notes on three cases of Gastralgia.

HUNTERIAN SOCIETY.—The second annual Hunterian Society's lecture was delivered by Sir William Mitchell Banks on Feb. 27th upon the Neglect of the Actual Cautery, Dr. Dundas Grant, the President, being in the chair. The lecturer said it was difficult to explain how so valuable a remedy as the actual cautery should have fallen almost entirely out of use; he could only ascribe the fact to "fashion." The operation was painless, being done under chloroform, and the after-pain was easily controlled. Failures in the use of this remedy were often due to a want of thoroughness in applying it. The iron, which should be at white heat, required a longer application than was usually believed to produce a good result. The skin should be almost completely destroyed. The cases most suitable for this treatment were those which were accompanied by deep-seated pain, such as periostitis and ulcerative arthritis; pruritus ani also in its most obstinate form yielded to this remedy. Cases were described in which immediate relief had been effected after long and continuous suffering. The cases of pruritis ani had presented patches of skin resembling damp wash-leather—a characteristic appearance of the chronic form of this disease.

ÆSCULAPIAN SOCIETY OF LONDON.—A meeting of this society was held on March 8th, Mr. W. C Worley, the President, being in the chair.—Dr. A. Haig read a paper on the Causation, Prevention, and Treatment of Anæmia. He defined anæmia as defective metabolism due to a defective circulation, which in turn was an outcome of uric acid excess in the circulation. He pointed out the slow "capillary reflux" in such defective circulations in a diabetic man and connected this state with Raynaud's disease—a more aggravated condition of the same circulatory defect. He also pointed out that the alternating chlorosis and rheumatism of girls was readily explicable on the theory of the alternate taking up and throwing out from the circulation into the joints of uric acid—the blood breaking up as a consequence of the uric acid in the circulation, producing chlorotic anæmia. He said that he more often treated anæmia by mercury than iron and always by advising the discontinuance of a uric acid diet, in which the avoidance of tea, coffee, and cocoa was as essential as meat and beef-tea. He showed his card for the ready estimation of the blood decimal and asserted that only with a diet free from uric acid was the best blood obtainable.

ROCHDALE AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on March 7th.—Mr. W. Stanwell read a paper on Diabetes. In discussing the etiology of the disease he gave an account of the physiological researches on carbohydrate metabolism. An interesting point was that in one case careful observations had shown that on a diet with potatoes the patient had less sugar in the urine than on the same diet without potatoes. A demonstration was given of various useful tests for sugar in urine, including, besides Fehling's and other well-known reactions, those with

methyl blue and safranin. The precipitation of glucose in urine by benzoyl chloride was shown and the fact of all the sugar being contained in the precipitate and none in the filtrate was demonstrated. The phenyl-hydrazin test was performed and the crystals were shown microscopically. The nitro-prusside of sodium test for acetone was also shown. For quantitative determination in ordinary practice the fermentation method was recommended.—Dr. W. J. Kerr, Dr. J. A. Ashcroft, Mr. J. Chadwick, and Dr. J. Melvin discussed the paper.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Kent Dispensary, Greenwich-road, on March 1st, Dr. Septimus Sunderland, the President, being in the chair.—Mr. Chisholm Williams and Dr. Walls showed a case of Ventral Hernia.—Dr. James Donelan read notes of a fatal case of Exophthalmic Goitre and showed a specimen.—Dr. F. S. Toogood showed cases of Congenital Heart Disease and Infantile Scurvy.—Dr. Dockrell exhibited some "Paratuberculides" with their microscopic conditions.—Mr. Chisholm Williams read notes on, and showed specimens of, Periosteal Sarcoma of the Tibia and Melanotic Sarcoma of the Little Toe.—Dr. Henry showed a case of Retinitis Pigmentosa with Nystagmus.—The cases were discussed by Dr. Dockrell, Dr. Scholefield, Mr. R. V. Donnellan, Dr. Toogood, Mr. J. P. Purvis, Mr. C. C. Weeks, the President, Mr. A. E. Joscelyne, and others.

Reviews and Notices of Books.

A Text-book of the Practice of Medicine. By JAMES M. ANDERS, M.D., Ph.D., LL.D., Professor of the Practice of Medicine in the Medico-Chirurgical College, Philadelphia. Illustrated. Fourth edition. London and Philadelphia: W. B. Saunders and Co. Pp. 1292. Price 24*s*.

THE third edition of this work appeared in September, 1899, and that another edition should be so quickly called for is ample evidence of the favour with which the work has been received by practitioners and students. The book is probably better known in America than in England, and we may therefore say that it is intended to introduce the student to the present state of our knowledge of the practice of medicine in general and of the diagnosis, differential diagnosis, and treatment of disease in particular.

The differential diagnosis has in many instances been tabulated. This is a most convenient plan for reference. The busy practitioner has no time to turn over several volumes to find the main diagnostic points in diseases closely simulating one another, but by means of such tables as are here given the symptoms, physical signs, &c., that are to be mainly relied upon in coming to a conclusion can quickly be comprehended. These tables are accurately drawn out and form a valuable and distinctive feature of the work.

The present edition has been fully brought up to date and the text has been carefully revised throughout, and considerable new matter has been added with a view to enhance the general usefulness of the work. The section on Diseases of the Digestive System in particular has received numerous additions. Not only have several of the sections been re-written, but new ones on some of the rarer or more fully recognised conditions have been added, such as those on Sprue, Ileo-colitis in Children, and Acute Cholecystitis. The remarks on Sprue are very brief, and we scarcely think that any practitioner would be able to recognise a case from the description here given. The section on Acute Infectious Cholecystitis is more full. Dr. Anders recognises three pathological varieties—catarrhal, suppurative, and phlegmonous; the bacteriology is dismissed in two lines, but the symptoms, and more particularly the differential diagnosis, are well described.

The part of the work devoted to a consideration of Diseases of the Blood in the Ductless Glands is complete and contains a summary of the many advances recently made in our knowledge of this subject. Dr. Anders divides the subject of anæmia into Primary or Essential Anæmia and the Secondary Anæmias, including under the latter "leukocytosis," "leukocythæmia," "pseudo-leukæmia," "splenic anæmia," and "anæmia infantum pseudo-leukæmia," designating by the last-named a form of anæmia first described by von Jaksch which occurs in childhood and which has certain similarities to leukæmia but is without the tendency to a fatal end.

The book as a whole may be described as very practical; theoretical questions are but little touched upon. We believe, therefore, that it will be found more useful to practitioners than to students who are preparing for their examinations.

A Manual of the Diagnosis and Treatment of the Diseases of the Eye By EDWARD JACKSON, A.M., M.D., Emeritus Professor of Diseases of the Eye in the Philadelphia Polyclinic. With 178 Illustrations and Two Coloured Plates. London and Philadelphia: W. B. Saunders and Co. 1901. Pp. 604.

PROFESSOR JACKSON, the author of this work, is well known both in the United States and in this country as an ophthalmologist of repute who has studied with care, and written well upon, the dioptrics of the eye, and as he has his own clinic in Philadelphia and his own class to instruct it is not surprising that he should find it necessary to publish a treatise which constitutes an authoritative exposition of the views and opinions that he has been led to form and of the methods of treatment, operative or otherwise, on which he is disposed to rely. The general arrangement of the work offers no novelty and differs but little from the ordinary manuals. The examination of the patient both by direct and oblique illumination, by means of the ophthalmoscope, and by means of lenses determining his refraction; disorders of the ocular movements; diseases of the several tunics and humours; glaucoma; diseases of the lids, lacrymal apparatus, and orbit; injuries of the eye; topical remedies; operations and the ocular symptoms connected with general disease—are the titles of the several chapters, and embrace all the forms of eye disease that are likely to fall under the observation of the general practitioner. Professor Jackson is catholic in his pathology and treatment of ophthalmic disease. He gives mercury in iritis; admits two forms of sympathetic disease—sympathetic inflammation and sympathetic irritation; and acknowledges that up to the present time the etiology of the sympathising eye, or the channel through which the exciting eye acts upon the uninjured one, is unknown. The different theories that have been advanced to explain this affection are briefly but clearly given. He practises iridectomy for cases of increased tension in preference to sclerotomy or Hancock's operation. He uses a knife of his own device for the section of the cornea in the extraction of cataract. It is a narrow Beers knife, with the basal angle much rounded, and no doubt acts well. In this operation it is not so much the form of the knife as the skill with which the operator manipulates it that is of importance, and those who have lived long have seen excellent results with many different forms of instrument. Professor Jackson's incision is made well within the periphery of the cornea and he omits the iridectomy.

The principles of the direct method of examination with the ophthalmoscope for the measurement of refraction are clearly given. The author justly observes that this method cannot be relied upon for the accurate prescription of glasses. The subject of skiascopy is treated of in several parts of the book. There is a short section devoted to it, but it is also considered under the head of astigmatism; he concludes his remarks on this point by recommending to the student the stenopæic slit or the parallel lines with spherical lenses if he

cannot use skiascopy or has no ophthalmometer, the usual condition, we imagine, of the student. Some examples of the combinations of glasses required for the correction of varying degrees of astigmatism might with advantage have been given. Professor Jackson commends the use of glasses at as early an age as three in cases where a tendency to squint is observed. In speaking of myopia he attributes that affection to two circumstances, first to softening of the scleral coat by congestion and secondly to pressure of the muscles around the eyes in fixing near objects. Surely other potent causes are insufficient light and close work on near objects. He speaks with approval of the removal of the lens in cases of high myopia. We doubt whether it will come into very general use. A useful bibliography terminates each chapter. The coloured illustrations are poor and rough, contrasting badly with the beautiful plates issued by the Germans, and showing that the Americans, like ourselves, are far behind that ingenious nation in chromolithography. The work has been written with care, has but few typographical errors, and may be considered to represent fairly in moderate compass the present state of ophthalmology.

Progressive Medicine: A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by HOBART AMORY HARE, M.D., assisted by CHARLES ADAMS HOLDER, M.D. Vol. III. September, 1900. London: Henry Kimpton. 1900. Pp. 408. Price 12*s.* 6*d.*

THE general scope of this work is too well known to need any introductory remarks from us. The present volume is concerned with diseases of the thorax and its viscera, including the heart, lungs, and blood-vessels, diseases of the skin, diseases of the nervous system, and obstetrics. The first section—that on Diseases of the Thorax and its Viscera—is by Dr. William Ewart who gives an excellent and valuable *résumé* of the more recent work which has been published concerning these diseases. He refers to the "serum treatment" of pneumonia, which, although the rational remedy, has hitherto fallen far short of our requirements, but of which some observers, more particularly Dr. Washbourn, speak hopefully but with considerable reservation. The contributions on Pulmonary Tuberculosis to which Dr. Ewart refers are very numerous. Amongst other observations he refers to those of Huguenin, who maintains that the clinical distance between the cases of virulent type and that (fortunately more frequent) of short, local, non-infective, often latent and generally curable affections is to be attributed to the presence or absence of life in the infecting bacilli. In infections with dead bacilli a spread of the disease is impossible, as dead bacilli do not multiply, and no infections of glands and secondary infection with cocci are observed. Bacilli may be found in the sputum for weeks, but inoculation proves them to be dead. These observations are interesting, and if the facts are corroborated by other observers should prove of considerable value from a point of view of prognosis. The surgical treatment of pulmonary tuberculosis is also referred to, although but little, if any, advance has been made in this direction.

In considering the treatment of aneurysm Dr. Ewart comments on the hypodermic injection of gelatin. The various published reports are altogether favourable, although it must be constantly borne in mind that this treatment is attended by risk and that the fatal accidents reported may occur again in spite of all precautions. The internal administration of gelatin has also been tried with encouraging results. No harm could arise from adding gelatin to the scanty diet of patients undergoing the simple rest cure, though, as Dr. Ewart remarks, we should not expect much result if the patient was taking at the same time iodide of potassium which rather tends to keep the blood fluid.

Much work has recently been done in the examination of the blood. The value of the observation of leucocytosis as an indication of the formation of inflammatory affections, such as appendicitis, is gradually being recognised and receives due notice in this volume.

We would also draw attention to the paragraphs on the use and abuse of digitalis, a subject upon which some confusion still exists. Dr. Ewart here states the indications for the administration of the drug or the reverse very minutely, and his remarks are well worthy of perusal.

That part of the volume devoted to "Diseases of the Skin" has been edited by Dr. Henry W. Stelwagon. His observations on X-ray Dermatitis and Eczema are particularly noteworthy.

Dr. William G. Spiller is responsible for the section on Diseases of the Nervous System. He has paid especial attention to clinical neurology, and papers of interest only to the anatomist or pathologist have received but slight recognition. We commend this course, for in a publication of this nature those matters which are of service to the practitioner should be especially selected. The paragraphs devoted to Tumours of the Brain are very interesting and we endorse Dr. Spiller's opinion when he says: "If men would sacrifice their vanity to the extent of publishing their mistaken diagnoses in important cases we should probably learn more than we do from cases in which a very careful diagnosis is made *after* the necropsy has been performed, because the mistaken diagnoses are often the instructive ones." We all of us learn by our errors but are chary of imparting that means of our knowledge to others.

The subject of Aphasia is a difficult one and Dr. Spiller has carefully recorded the principal advances which have been made in the investigation of this symptom.

"Babinski's reflex" would appear to be a valuable sign in distinguishing between certain organic and functional disorders, and it is to be hoped that the value of this sign will be proved by further observation. In organic lesions of the cord Babinski found that the normal flexion of the toes in the plantar reflex is replaced by extension, and the phenomenon has been observed in other conditions, but never in "hysterical" affections.

The work which has been done in Obstetrics is commented on by Dr. R. C. Norris and the abstracts have been selected with the same care as in the preceding sections. We note some valuable remarks on the Heart in Pregnancy, a matter which frequently gives rise to much anxiety on the part of practitioners and the patients' friends. The danger of heart disease in pregnancy has probably been usually over-rated, but at the same time the question as to whether a woman suffering from valvular disease should be advised to marry or not is an extremely difficult one and each case must be decided individually.

We consider this publication a most useful one and to those practitioners who desire information on the subjects treated therein we can certainly recommend it.

Studies from the Department of Pathology of the College of Physicians and Surgeons, Columbia University, N.Y. Vol. VII., for the Collegiate Year 1899–1900. Reprints.

THE Department of Pathology, the director, Dr. Mitchell Prudden, and the authors of the papers collected in this volume, are alike to be congratulated on the amount, variety, and value of the work published. The book contains a series of 14 papers dealing for the most part with experimental pathology and all marked by great care and completeness. The papers are reprints from the current medical journals in which they originally appeared. This method of publication is adopted because, in the opinion of the director, "the aims of such varied studies are more certainly accomplished" thus than by departmental or university

publication. This plan leads to a certain loss of typographic homogeneity, and if any adverse criticism of the work may be made it is that there appears to be a similar lack of homogeneity in the subject matter of the papers, there being no appearance of any leading idea round which the work of the department is grouped.

Dr. E. Hodenpyl treats in the first paper of Miliary Tuberculosis of the Pleura without other tuberculous lesions of the lung, and calls attention to the fact noted by Professor Delépine and others that infection may take place in a direction opposed to the lymph and blood streams. Practical hygiene is represented by a paper by E. W. Firth on the Relation between the Micro-organisms of the Air and Various Methods of Cleaning adopted in Public and Other Buildings. The observations were made by means of a simple Petri sand filter attached to a small portable apparatus devised by Dr. Prudden and showed that dry-dusting doubles the number of organisms present in the air and that these do not settle again for some long time, dependent on ventilation and other factors. There is a short, able, practical experimental study of secondary cataract by Dr. W. H. Bates, designed to discover the cause and to avoid the occurrence of this complication. He concludes that secondary cataract is not caused by a thickening of the posterior capsule but by the development of connective tissue replacing fibrin formed in the anterior chamber by the coagulation of fluid exuded at the time of operation. A long paper by Dr. G. Langmann treats of Snakes and Snake Poison, in which he concludes that, in spite of some weighty opposition, antivenene (Calmette) must be considered the only reliable antidote. An elaborate, detailed, and accurate account of the pathology and treatment of tetanus, together with a complete bibliography, is contributed by Dr. A. V. Moschcowitz. The paper includes an analysis of no less than 290 recorded cases treated by subcutaneous injection of antitetanic serum and 48 cases treated subdurally. The mortality in tetanus appears to be more dependent on the severity, as estimated by the length of the incubation period, than on the treatment. There is a greatly diminished mortality when the incubation period exceeds ten days.

Traumatic Hæmorrhages into the Spinal Cord are treated by Dr. P. Bailey and pharmacology is represented by Dr. S. J. Meltzer's paper on the Toxicology of Potassium Chlorate, while a very valuable paper on Serum Globulin and Diphtheria Antitoxin is contributed by Dr. P. H. Hiss and Dr. J. P. Atkinson. In this they produce evidence that the magnesium sulphate precipitate from blood serum contains all the antitoxin.

There are other valuable papers, including one on a Streptothrix Infection of the Lungs by Dr. C. Norris and Dr. J. H. Larkin, in which a new method of culture on fresh tissue is described.

The articles are sufficiently and in some cases admirably illustrated. We should be glad to see a collection of articles of equal merit to these issued by the pathological departments of our own universities. In future issues, for the instruction of possible English readers, it would be well if the editor of these studies would indicate the price of the volume and where it may be obtained.

Kursus der Pathologischen Histologie mit einem Microskopischen Atlas enthaltend 35 Tafeln. (*Course of Pathological Histology, with Atlas.*) Von Dr. L. ASCHOFF, Privat-Docenten und 1. Assistenten am Pathologischen Institut zu Göttingen; und Dr. H. GAYLORD, Professor der Chirurgischen Pathologie und Direktor des Staatlichen Instituts für Krebsforschung der Universität Buffalo. Wiesbaden: J. F. Bergmann. 1900. Pp. 340. 35 Plates. Price 18*s*.

THIS work consists of a systematic description of the pathology of the various organs in conjunction with a series of excellent photo-micrographs designed to illustrate the pathological histology of the lesions. The atlas consists of 35 plates, each containing some six or eight photographs reproduced by a collotype process which has the great advantage that it permits the use of a lens and thus enables many details to be observed which are not visible to the naked eye. Speaking of the photographs as a whole they are excellent in their definition, equality of lighting, and other technical qualities. The reproductions are worthy of the photographs. Such illustrations are, as a rule, so expensive as to be prohibitive, and the beautiful atlas of Karg and Schmorl is for this reason out of the reach of the student. The price of the present work is so small that it is difficult to understand how it can have been produced profitably. There are in addition to the photographs a few plates of coloured drawings and the last three plates of the atlas form a new departure in pathological illustration, being reproduced by a photographic three colour-printing process which certainly seems, especially in the case of the last plate, to give very good results. The photographs appear on the whole to be good illustrations of the pathological processes, but there is undoubtedly a limit to the value of a photograph for this purpose, and it is doubtful whether a student would learn much from the representations given of round-celled and spindle-celled sarcomata. Most of the illustrations are taken with low powers and this diminishes the photographic difficulty greatly but renders some of the illustrations of micro-organisms of slight value, though there are some good representations of anthrax bacilli in tissues. There appears to be no indication of the magnifications employed, and in many cases the methods used in the preparation of the specimens are not given. This is a fault of some importance, as it becomes difficult to interpret such illustrations, for instance, as those which represent lesions of the spinal cord, and there seems to be no illustration of Marchi's method (given in the text), which alone enables the degeneration of individual fibres to be traced. There is an excellent photograph of the rare condition, argyria of the kidney. The systematic description is preceded by a section on histological methods which is good and up to date. The processes are described in a thoroughly practical manner. The fixing and hardening methods are clearly given and there is an excellently succinct but sufficient description of the short and rapid methods of use to the practising physician. Special methods are conveniently arranged under headings indicating the objects for which they are employed. Macallum's method for the demonstration of iron appears to be omitted. The importance of the hardening methods used in relation to the stains to be subsequently employed is clearly pointed out.

The last section of the book deals with Photo-micrography. There is a good index. The book is a valuable addition to existing works on pathological histology.

LIBRARY TABLE.

A Manual of Syphilis and the Venereal Diseases. By JAMES NEVINS HYDE, A.M., M.D., Professor of Skin, Genito-urinary, and Venereal Diseases, Rush Medical College, Chicago, &c.; and FRANK HUGH MONTGOMERY, M.D. Associate Professor of Skin, Genito-urinary, and Venereal Diseases, Rush Medical College, Chicago, &c. Second Edition, Revised and Enlarged, with 58 Illustrations in the Text and 19 Full-page Lithographic Plates. 1900. London and Philadelphia: W. B. Saunders and Co. Pp. 594. Price 17*s*.—This second edition is in many ways a distinct advance on the first, and especially worthy of notice is the addition of a series of lithographic plates taken from Mracek's "Atlas of Syphilis and the Venereal Diseases," which we reviewed in 1899. In this volume they are on a rather larger scale than in Mracek's works and the general effect is certainly

better. The account of gonorrhœa has been almost rewritten, and many minor alterations have been made. The description of syphilis is excellent, and the only criticism which we would offer is that the authors' objections to the employment of "primary," "secondary," and "tertiary stages" in the account of the disease are somewhat fanciful. No one at the present time imagines that in any particular case the disease must pass through all these stages *seriatim*, and the fact that these terms were misused and misunderstood at one time is not a sufficient reason for their disuse in view of the convenience of their employment. A valuable chapter is that on syphilophobia and venereal hypochondriasis. The descriptions of the forms of gonorrhœal rheumatism are hardly as clear as might be desired. There are three distinct varieties of joint affection in gonorrhœa; in the first form no bacterial infection of the synovial cavity can be discovered, and we are justified in looking on the synovitis as the result of the action of the toxins which have been absorbed; in the second form the gonococcus is found in the exudation into the joint; and in the third form, in which the symptoms are most severe, the synovial cavity is infected by the gonococcus and by some other pyogenic micro-organism as well. The results of the several forms serve usually to differentiate them. The book is a trustworthy guide to an important subject.

On Sanitary and Other Matters. By GEORGE S. KEITH, M.D. Edin., LL.D. Aberd, F.R.C.P. Edin. London: Adam and Charles Black. 1900. Pp. 124. Price 2*s* 6*d*.—If obvious sincerity could carry conviction this little volume of essays would effect reforms in our national hygiene of a very drastic order. For instance, Dr. Keith bewails the reckless waste of water manifest in the methods we adopt for urban sanitation, suggests the substitution of "earth and pail" for water and pipe, and of a wet sheet for the morning tub. Although strong arguments are brought to bear on the reforms suggested they are hardly likely to shake our faith in such thoroughly British institutions as the water-closet and the cold bath. In other departments of personal hygiene Dr. Keith's views are more likely to gain adherents. Of the rapid and progressive deterioration of the young in this country the author supplies sufficient proof, and if his reforms could be generally accepted doubtless there would be a great conservation of national vigour. Chapter V. is devoted to the Story of an Eye, a most instructive example of the efficacy of Dr. Keith's methods. The invaluable experiences of a long life's work in general practice by a man of keen observation and Scotch shrewdness are well worthy of respectful attention. Few practitioners at the end of a busy career have the energy to record for the benefit of younger men the experiences which their age and observation can provide. Many of the text-books which young practitioners and students read for their instruction are written by authors who can claim neither of these essentials. Dr. Keith's experiences should not be overlooked by practitioners who take an intelligent interest in natural methods of healing.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Fritz Egger has been promoted to an Extraordinary Professorship of Medicine, and Dr. Carl Hägler to an Extraordinary Professorship of Surgery.—*Berne:* Dr. Otto von Herff of Halle has been appointed to the chair of Midwifery and Gynæcology vacated by the migration of Professor Bumm to Halle.—*Cracow:* Dr. Stanislaus Maziarski has been recognised as *privat-docent* of Histology.—*Tübingen:* Dr. C. Bürker has been recognised as *privat-docent* of Physiology.—*Vienna:* Dr. Anton Freiherr von Eiselsberg of Königsberg has been appointed to the chair of Surgery held by the late Professor Eduard Albert.—*Zürich:* Dr. M. Freudweiler has been recognised as *privat-docent* of Hydrotherapy and Dr. Otto Veraguth as *privat-docent* of Neurology.

Analytical Records
FROM
THE LANCET LABORATORY.

TABLOIDS: (1) QUININE BISULPHATE AND CITRATE (EFFERVESCENT); AND (2) PILOCARPINE NITRATE.
(BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUILDINGS, LONDON, E.C.)

THE combination of a saline febrifuge such as potassium citrate with quinine is valuable. In this tabloid one grain of quinine bisulphate occurs with 15 grains of potassium citrate. The tabloid is first powdered before the addition of water when an agreeably effervescing draught is obtained. The draught offers also the advantage of being sedative in its effect upon the gastric coats owing to the carbonic acid gas. Tabloids of pilocarpine nitrate contain one quarter and one-tenth grain respectively of the alkaloidal salt. It appears that there is considerable variation in the physiological effects of the galenical preparations of jaborandi, but that the use of pilocarpine is reliable for full physiological action. The best salt for the purpose is said to be the nitrate, which has been used with promising results in uræmia. The salt also has been tried in all stages of croupous pneumonia and in diphtheria. The pilocarpine nitrate tabloid is quickly soluble in water.

(1) DIGIT TOILET SOAP; AND (2) LAUNDRY WASH.
(THE WAGEL SYNDICATE, LIMITED, 254A, HIGH HOLBORN, LONDON, W.C.)

The sample of toilet soap submitted to us gave satisfactory results on examination. It contained a minimum of water, is economical in use therefore, and, more important still, the ingredients are correctly adjusted so that there is no alkali in excess. The soap further is free from irritants. The laundry wash is a soap specially prepared for the cleansing of linen and similar fabrics. It is of jelly-like consistence and contains a proportion of free alkali. It is very cleansing and contains no injurious chemicals.

CYPRIDOL.
(WILLCOX AND CO., 49, HAYMARKET, LONDON, S.W.)

"Cypridol" is the name given to a so-called "bin-iodised" oil. For administration the oil is contained in capsules. It is a clear yellowish oil with a creasote-like smell. According to our analysis it contains both mercury and iodine. It is regarded as containing a "nascent bin-iodide" dissolved in a strictly neutral antiseptic oil. It is given by the mouth or by hypodermic intra-muscular injection in venereal diseases. There is considerable testimony in favour of administering mercury in this form and by these methods.

"MÜNCHENER LÖWENBRAU" LAGER BEER.
(THE MUNICH LION-BREW CO., 62, HOLBORN-VIADUCT, LONDON, E.C.)

This beer is brewed in Munich and sent to this country in special ice wagons and subsequently bottled at the depôt in London and Pasteurised. On analysis it presents the characteristic features of the well-known brown Bavarian beer. The results were as follows: malt extractives, 6·09 per cent.; mineral matter 0·17 per cent.; alcohol, by weight 4·62 per cent., by volume 5·78 per cent., equal to proof spirit 10·13 per cent. We have carefully tested the beer for impurities but with negative results. It is quite free from metallic contamination and there is not the slightest evidence of even the minutest quantity of arsenic which analysis is able to detect. The commendable point about Munich beer is that, while highly nutritious, exceeding in most instances the value in this respect of English beers, it contains a minimum of alcohol. Its flavour is pleasantly malty and the beer is undoubtedly wholesome and refreshing, this last quality being contributed

in no small measure by the presence of an important quantity of the soluble phosphate of potassium derived, of course, from the malt.

LOZONE.

(LOZONE WORKS, MARTIN'S-BUILDINGS, VINE-STREET, LAMBETH, LONDON, S.E.)

"Lozone" is a special preparation of peroxide of hydrogen which by reason of its purity is well suited for medicinal use. Peroxide of hydrogen has been used internally in both gastric and intestinal troubles. The special feature of "lozone" is that, unlike most preparations of peroxide of hydrogen, it is quite stable. We gained proof of this by the fact that analysis showed on two occasions precisely the same result in regard to its oxygenating value. We found that on one occasion the liquid contained 2·26 volumes of available oxygen. Three weeks later this value proved to be exactly the same, so that no loss of strength had taken place, despite the fact that no special precautions had been taken against external influences, such as light or exposure to the air. The preparation may obviously be relied upon.

GLYCEROLES (GLYCERINE TINCTURES).

(MACKEY, MACKEY, AND CO., 175, GRANGE-ROAD, BERMONDSEY, LONDON, S.E.)

The powerful solvent action of glycerine on the active principles of drugs is well known, and doubtless, from the pharmacological point of view, glycerine as an extractor is, in reality, an advance on alcohol. We have received specimens of the glycerine extracts or tinctures of nux vomica, opium, hyoscyamus, digitalis, cardamoms, and compound camphor. They are perfectly clear and staple preparations, and very convenient for administration or dispensing. The glyceroles are growing in favour. They are certainly elegant preparations.

KOLAX.

(FLETCHER, FLETCHER, AND CO., HOLLOWAY, LONDON, N.)

Kolax (or laxative cocoa) has been prepared in response to a want frequently expressed by practitioners for a simple, trustworthy, and palatable laxative. Kolax contains a well-known laxative extract and malted cocoa proves an excellent vehicle for its administration. The cocoa used is of excellent quality, as, according to our analysis, we found no extraneous fat or any evidence of alkali being used to make the cocoa "soluble." The combination affords a laxative in an agreeable guise.

KOLA WINE.

(L. M. DURLACHER, AGENT, 12, SAVAGE-GARDENS, TRINITY-SQUARE, LONDON, E.C.)

The genuineness of this wine is attested to by the fact that by operating on a large quantity we easily separated crystals of caffeine from it. It is said to be prepared with the best Jamaica kola nuts. The vehicle is a good port wine. On analysis the following results were obtained: extractives with sugar, 12·13 per cent.; alcohol, by weight 15·67 per cent., by volume 19·28 per cent., equal to proof spirit 33·79 per cent.

THE ARMY ESTIMATES.

MR. BRODRICK, who has admittedly proved himself to be a man of courage and ability, made a long and comprehensive statement in introducing the army estimates last week and clearly outlined the main points in the Government's new scheme of military re-organisation. In the first place, it may be stated that the army estimates amount to close upon £88,000,000, and it is proposed that the total strength of the British army should be brought up to nearly 700,000 men. Among the more important points raised by the War Minister were the necessity of having three army corps always ready, the increase of the artillery and mounted branches of the service, and the urgent need of reform in our medical and transport arrangements. Apart from war we have to maintain 115,000 men in India and the colonies and are dependent on voluntary recruiting. The existing system is to continue but is to be vastly developed; recourse is not to be had to compulsory service, but an efficient defence must nevertheless be had somehow, and there is to be no separate Indian army. It would be impossible, as well as altogether beyond our province, to accompany Mr. Brodrick through a speech extending over two and a half hours in delivery, but we may say that it is probably the most important and sweeping declaration of military policy and reform that has been made in our time—certainly since the abolition of purchase and the introduction of short service in the army

The new necessities of the empire have been accentuated and brought home to us by the experience and lessons which have been obtained and learned in South Africa, as well as by recent debates on the subject of army administration in the House of Lords. The consequence of all this has naturally been to focus public attention on the subject and to call forth an earnest attempt to frame a large, bold, and comprehensive measure of some sort dealing with every branch and department of the service. This attempt Mr. Brodrick has now made, and he has very plainly indicated the standard at which he is aiming and the principles by which he has been guided. There were many people who thought that the report of the Royal Commission on the South African Hospitals would share the fate of many of its predecessors in the way of Royal Commissions, which after giving rise to a hot fit of excited discussion are practically laid aside. But the consideration of the subject had not advanced very far before all speculation in this respect was brought to an end by the strong declaration of Mr. Brodrick in the House of Commons of his intended action in regard to the reform of the army medical service and of his determination to make any changes, however drastic, that were needed; nor did he omit to indicate rather significantly some of his own impressions on the subject which were not altogether favourable as to the effect of some of the changes which had been introduced into that service of late years.

We do not think, by the way, that candidates for the Royal Army Medical Corps are likely to be attracted by all the discussions that have taken place.

The first thing which strikes us in this new army scheme, which is undoubtedly, as we have said, a bold and comprehensive one, is, Where is the requisite number of soldiers to come from? We do not see that Mr. Brodrick has made this at all plain. He does not offer any additional inducement to enlist by any increase of pay, although he does promise the introduction of some changes which will probably tend to popularise the army. But the whole military system appears to stand in need of re-consideration. It should be seen whether changes could not be made which, without gravely affecting the discipline and efficiency of soldiers and corps, would better adjust army life to the tastes, habits, and social customs that obtain outside it. We readily admit that in all which concerns the health and comfort and convenience of the soldier there has been enormous improvement and that this improvement is still going on. Still, young fellows who will gladly submit to courses of drill and instruction in shooting are nevertheless not prepared to adopt a barrack-room life and to exchange their personal liberty for much that they find irksome, monotonous, and distasteful to them. In times of war it is different. Any latent patriotism or military ardour which may be present is sure to manifest itself then, and recruits are always forthcoming because of the love of adventure, excitement, and the contagious influence of their fellows. We want some plan by which the services of men of this stamp can be obtained and utilised to a far greater extent than is done at present, and we think that it might be accomplished if some plan could be devised by which men could be allowed to live out of barracks and to attend at stated times for drill, shooting, and field manœuvres. A number of such men would no doubt subsequently offer themselves for enlistment in the regular army. Many medical officers think that we require a different system of recruiting. The recruiting officers in a large city or town should occupy a position in a prominent street or thoroughfare instead of being hidden away in a back street or at some obscurely placed barracks. The station should fly a flag and have a good and rather attractive exterior and a clean, inviting, and well-appointed interior where all information could be obtained and the examination of recruits be carried out.

THE LANCET.

LONDON: SATURDAY, MARCH 16, 1901.

The Duties of House Surgeons at the East Suffolk and Ipswich Hospital.

A LETTER which we print on p. 815 gives the particulars of a dispute which has arisen between the Board of Management of the East Suffolk and Ipswich Hospital and the house surgeons of that institution, one result of which has been the dismissal of the two house surgeons from the posts to which they had recently been appointed. It appears to have been a custom at the hospital that the house surgeons should furnish upon a printed form particulars, for use in the local press, of the accidents the victims of which are from time to time brought to the hospital. With this custom Dr. KAY and Mr. WORTS, the present house surgeons, refused to comply on the ground that the medical man has no right to make public information with regard to patients under his care without the consent of the patients or at least without that of their near relatives. The matter was brought before the Board of Management of the hospital at one of their weekly meetings, and a resolution was subsequently passed by the board embodying the custom and making it an instruction from the board to the house surgeons. Whether this resolution was strictly in accordance with the powers of a weekly meeting of the board not specially summoned is not of immediate importance, but we will assume that as far as the formalities to be observed it was properly passed under the seventy-seventh rule of the hospital which lies before us. This rule states that "the board of management with the consulting and honorary members of the medical staff shall have power at any meeting specially summoned for that purpose to make and issue, and from time to time to alter and amend, regulations for the guidance of all or any of the paid officers and servants of the hospital, and such officers and servants shall observe and abide by such regulations. Copies of the regulations shall be hung up in such parts of the hospital as the board shall from time to time direct."

Assuming that the prescribed formalities have been complied with we are still compelled to doubt whether the regulation is one the infraction of which would entitle the board of a hospital to dismiss house surgeons who accepted office before it was made and who declined to be bound by it; while we also emphatically question the wisdom of such a regulation. It must be taken to have been the intention of those who framed the seventy-seventh rule (which we have quoted) that the regulations made under it by the Board of Management should be reasonable regulations, fit and proper "the paid officers and servants of the hospital" in their several capacities to obey. In our view, for instance, a new regulation that the house surgeon should scrub the wards or write a weekly article in a local newspaper would clearly be beyond the powers of any Board of Management to make and to enforce. And we think that it is unreasonable for the board to expect their house surgeons to transgress what they feel to be the spirit of medical ethics—a feeling in which they have our unqualified support. The new regulation that the board have made is carefully worded with discreet vagueness, but as it intimates that information to the press shall be given "according to precedent" it would seem that they require the filling up of the form published in Dr. KAY'S letter to us. Now furnishing information to the press cannot by any stretch of imagination be brought within the reasonable duties of any house surgeon, in addition to which medical ethics forbid, as our correspondent rightly contends, the furnishing by a medical man of information concerning his patients to anyone, unless the patient or his family has consented to its being imparted. It will be seen, moreover, that the form supplied to the house surgeons at Ipswich indicates particulars of which a house surgeon can have no personal knowledge and for which he is asked to take responsibility by appending his signature. We may assume that he is intended to state the nature of the injuries received by his patients, although this—the only matter really within his cognisance—is not definitely asked for; while he is in terms desired to give the patient's name and address, the place and time of his injury, and the nature of the accident. Whether these are fit and proper points whereon the reporter should exercise his ingenuity and zeal we will not discuss; our contention is that they do not come within the province of the house surgeon, while the publication of them by him would involve him in serious responsibility. Many accidents that come into a hospital form at some time or other the subject of legal inquiry. The criminal courts deal with injuries wilfully inflicted, in the civil courts insurance companies dispute their liabilities, those injured by the negligence of others seek compensation, and employers are sued by their workmen for injuries sustained in their employ; while a recent Act of Parliament has now extended the Workmen's Compensation Act so that on and after July 1st next it will embrace agricultural labourers. In such cases the house surgeon is an all-important witness where the injured person has been treated in a hospital, and it is grossly unfair to such a witness that he should be compelled to make public his first impressions of the extent of injuries and the cause of them with regard to which he will, perhaps, at some future date be examined and cross-examined in a court of law. A premature statement thus publicly made may, whoever has made it, prejudice most unfairly the case of a complainant or of a defendant, even though it be substantially accurate. Still more may it do so if some, perhaps unavoidable, mistake has occurred in it. In such a case the hospital which concurred in the mistake being made, and the house surgeon or other person who consented to make it, would be likely to undergo hostile and damaging criticism, if no worse resulted.

Let us take such an announcement as this for example. "JOHN SMITH is lying in the East Suffolk and Ipswich

Hospital suffering from concussion of the brain and other injuries received when driving a team on the farm of Mr. HENRY JONES of such-and-such a parish." This we conceive is the kind of information which the house surgeon is expected to furnish in more precise terms, affixing his signature to names, dates, and times which he can only have learned by hearsay. The paragraph may be perfectly accurate but the statement may damage "JOHN SMITH" in the eyes of some one from whom he seeks employment and who may have a prejudice against a workman who, as he has read, has not been skilful enough to avoid an accident and who has, moreover, suffered from concussion of the brain; while under the new law referred to such a statement will also imply liability on the part of "HENRY JONES" to pay compensation to an injured labourer. This again may, in the case of a man known not to be well off, gravely affect the credit of "HENRY JONES." Therefore, if the statement be perfectly true it may seriously displease and inconvenience both SMITH and JONES, while if by any error wrong names and places have been given, or some exaggeration has taken place, either of them may have substantial cause of complaint. We have accordingly, for such reasons as we have given and for such as are contained in Dr. KAY'S reasonable letter, come to the conclusion that the new regulation of the Board of Management of the East Suffolk and Ipswich Hospital is one which the board should neither have made nor insisted upon, while the custom upon which it was founded was undesirable in the interests of the hospital as well as those of its officers. We hope that the editor of the newspaper, to whom allusion has been made by name, will reconsider the matter if his views have been correctly indicated. As a member of the Board of Management of the hospital he will no doubt feel it incumbent upon him to adopt that course only which he is satisfied is best for the interests of the institution, of which interests he is a trustee. As journalists we are in full accord with him when he says that "a paper must be run"; but we are sure that he would imply when using such words that it must be "run" properly. Now it is not proper for the house surgeons of the East Suffolk and Ipswich Hospital to make the statement about their patients in the daily press that is required of them. To do so is ethically wrong. It is unfair to the patients; it may involve the hospital in discredit; moreover, the house surgeons cannot know, save by hearsay, the things which they are required to vouch for with their signatures.

"The Status of the Country Doctor."

WE publish to-day an address on "The Status of the 'Country Doctor,'" by Mr. HARRY ROBERTS, B.Sc. Lond., L.S.A. Mr. ROBERTS speaks with the authority of one who lives in a country town of some 1100 or 1200 people, which is well supplied with the class upon whose influence, past and prospective, he descants with much originality and independence. "The country doctor" is a favourite subject of novelists and other writers. Mr. ROBERTS does not mean by this description only those who live in small villages, but virtually all general practitioners as distinguished from the "separate class of physicians" who, in past days, "although frequently ignorant of medicine, were almost invariably men of culture and wide knowledge, as these were then accounted." The general drift of his address is to magnify the change in the conception of culture which has taken place since the study of science began to compete seriously with the study of classics. Familiarity with Latin and Greek writers is, in his opinion, mere pedantry, knowledge bounded by words, and so of little value. Culture implies acquaintance with the points of view of the great writers and dreamers of the world—modern as well as ancient; it requires us to have lived freely among people of many conditions, and to "have spent much time among the higher regions of existence." Culture must result in greater tolerance, greater sympathy because fuller understanding, and withal, less pomposity. It is the belief of Mr. ROBERTS that the medical practitioner, in virtue of his better education, as compared with that of his predecessors and with that of the clergyman, is in the way of acquiring this higher culture, and with it a predominant influence even over "the parson" who until lately was the only educated man in the country parish. Mr. ROBERTS is anxious for the development of this true culture in medical men in order that they may still further improve their status, their influence, and, to quote his words, their "power of materially modifying the structure of provincial life."

In the main we agree with Mr. ROBERTS. We have often pointed out the steady growth of the influence of medical men in society; and in our opinion the growth of this influence must be progressive if they are true to their opportunities and their duties. This will be the case all the more if we do not too pointedly arrogate to ourselves the first influence in communities. We have enormous advantages. Our profession as a scientific one is practically undivided. We are not broken up into schools that strive for mastery and disparage their rivals. As the scientific basis of our position and practice is developed our influence must be more and more unassailable—unless some judicial blindness should overtake civilised communities, as almost seems to be the case in respect of certain of the best-established facts in medical science. It is probable that the scepticism to which we refer is a mere temporary phase of civilised ignorance which experience—perhaps very rough experience—will correct. The ordeal of suffering, if nothing else avails, will bring men back to sanity and to obedience to the laws of health and of disease which it is our high function to study. And unless our study be very superficial and perfunctory it must give us such an advantage as to compel the growing respect of men and of communities. It is a large ambition to modify materially the structure of provincial life. But even this should be possible to men following the calling of FOTHERGILL and JENNER, of ALISON, of FARR and CHADWICK, of LISTER and SIMON, who have influenced legislatures at home and abroad. The members of our profession in small districts should have in some sense an easy triumph. They have, it is true, more ignorance and prejudice to overcome. But they are in closer contact with the victims of these defects. They are the chief representatives of science in their districts. They count for more than men who are lost in large communities, and the development of municipalism

gives them local chances which are not always obtainable in great cities.

Mr. ROBERTS is too severe in his criticism of the faults that hinder the influence of the country practitioner. Prominent among these he considers a certain pomposity or bumptiousness which has been the favourite theme of satirists from JOHN OF SALISBURY downwards, due mainly, he thinks, to two causes—firstly, a lack of knowledge of the great book of wisdom outside our own handicraft, and, secondly, our lack of humour as a profession. There is some truth in this view, but a very diminishing quantity. We admit the defect of humour, and it is a great defect, and we heartily endorse Mr. ROBERTS'S advice in favour of a little more study of the humorists and their reflections on our profession. On the other hand, it strikes us that Mr. ROBERTS takes the humorists a little too seriously and applies their satires a little too literally to the profession of the present day. We claim to have some knowledge of the country practitioners of the last and the present generations, and we venture to think that very few of them would be found to answer to the description of JOHN OF SALISBURY or even to that of CHARLES DICKENS, either as respects pomposity or the zeal with which they have haggled for fees—which is another of the faults by which, according to Mr. ROBERTS, we defeat our purpose and lower our status in the community. But while we differ from Mr. ROBERTS as to the degree to which the profession is now open to the satires which have been heaped upon it in the past we agree in his main contention that the influence of our profession is increasing and must increase, and that this increase can only be hindered by our own failings in the pursuit of truth and our own bearing towards those who are less fortunate and less instructed than ourselves. Unfaithfulness in our own work and the assumption of airs of superiority will delay indefinitely that influence which society shows an increasing disposition to accord to those who really study medicine and who apply its discoveries in an earnest and reverent spirit to ameliorate the conditions of modern life.

The Medical Staff and the Management of the National Hospital for the Paralysed and Epileptic.

OUR readers will be interested to know that the controversy between the medical staff and the Board of Management of this hospital has entered upon a fresh, and it is to be hoped a final, phase. It is desirable to recapitulate the various steps in the campaign, and it may be stated at the onset that, however absurd it may seem, the whole trouble has arisen through the refusal of the board to entertain the request of the staff that two of its members should be annually elected to the Board of Management. About 10 years ago the staff first made this request, but the board declined it, substituting instead occasional meetings between the house committee and the staff. This arrangement was summarily, and without any reason apparently, discontinued by the board at whose suggestion it had been instituted. The method then proposed by the board for communication between that body and the staff was by means of two delegates of the latter, who might ask to meet the board or be invited to meet them, in order to discuss matters of medical interest or importance in the administration. The staff accepted this arrangement on the distinct understanding that the delegates were to be present at all the discussions on the subjects concerning which their views and opinions were asked. In connexion with the establishment of a system of payments by out-patients this arrangement was violated by the board and the subject on which their advice was asked was discussed while the delegates were absent. The staff naturally declined to have anything more to do with a system which the board could so manipulate as to make it quite useless for the purposes for which it was instituted. This led to a fresh demand from the staff for representation by means of the annual election of two of its members to the Board of Management. This demand was made at a special meeting of the board and staff at which several members of the staff as spokesmen for their colleagues presented a case which we think should have carried conviction. The board absolutely declined to entertain the proposal, not condescending to state any reasons for their action. The staff, now apparently for the first time, recognised that they were dealing with a deeply prejudiced board. Their next step was to address the governors. But meantime various details of maladministration, of faulty domestic and nursing arrangements, had come under their notice and they strengthened their appeal by a statement of these in their letter to the governors. Any ordinary person would now have thought that the board would take steps to inquire thoroughly and impartially into the charges. What they did was to appoint a sub-committee of themselves to inquire into their own defective administration—a sub-committee which naturally proceeded to find that everything was as nearly perfect as it well could be. Of course, the medical staff declined to submit their evidence to any such hole-and-corner inquiry. The board apparently remained uneasy in their own minds and the next step was to summon a meeting of governors.

A meeting of governors of the National Hospital for the Paralysed and Epileptic can be summoned by means of a single advertisement in any newspaper in the United Kingdom. An advertisement, which, we believe, appeared in the *Times* early in August, was all the notice which the governors who were known or suspected to be favourable to the staff received of the forthcoming meeting. Others, however, presumably those on whom the board thought they might depend, received a special notice and also a copy of a proxy in favour of the board which they were requested to sign and to return. According to the rules of the hospital proxies are only available after a ballot has been demanded upon any question submitted to a meeting of governors, so that the board, in asking for these proxies before the meeting, were acting illegally, and if they had even an elementary acquaintance with the rules governing the charity they must have known that they were acting illegally. The meeting was held on August 11th last and was attended by 16 governors. By a majority of 14 to 2—

and of the 14 six were members of the board or relatives of members—the meeting decided that representation upon the Board of Management should be refused to the staff and that no further inquiry into the affairs of the hospital was needed. A verbatim report of the speeches made at this meeting will be found in THE LANCET of August 18th, 1900, p. 551. It may be incidentally mentioned that in a letter to the *Times* of March 11th, 1901, from the secretary-director of the hospital (to which we shall have to make further reference) Mr. BURFORD RAWLINGS asks for "the continued approval of the many governors, including nearly all the chief contributors, who decided against the demand of the staff in August last." There was only one meeting in August and it was attended by 16 governors.

Of course, it was obvious that the staff could not consider such a pronouncement as final, and indeed they had protested against the manner in which the meeting was hurried through and had declined to take any part in it for that reason. The correspondence which now ensued in the daily press showed clearly that something more would have to be done, and in December last the board announced that the Lord Chancellor, a member of the Board of Management, had nominated Sir FORD NORTH to hold an inquiry into "the allegations of the medical staff concerning the care, comfort, and treatment of patients." The staff were informed of the intention to hold this inquiry three days, and only three days, before it was to take place, and were told that the board would be represented by counsel and that it was permitted to the staff to be similarly represented. It was scarcely to be expected that the staff would be satisfied with such a partial inquiry or with a tribunal which had no medical element in it. The staff, in short, declined to have anything to do with the inquiry, and as a consequence it was adjourned *sine die*, although it is significant of the unreasonable attitude assumed by the board that even their own counsel advised them to enlarge the scope of the inquiry and to have the assistance, if thought expedient, of two assessors, one nominated by the board and the other by the medical staff.

It will be remembered that in July last the Metropolitan Hospital Sunday Fund decided to withhold the usual grant to the hospital pending a settlement of the differences between the board and the staff. In December last the Prince of Wales's Hospital Fund took a similar step, intimating that unless matters were settled before May 1st the grant would not be made at all. Certain attempts were now made by friends of the board and of the staff to arrange some ground of agreement. These negotiations were more or less of a private nature, but as a consequence of them resolutions were passed by the board and by the staff with reference to the composition of a committee of inquiry and the matters with which it was to deal. So far as can be gathered the board wished this tribunal to decide upon the matters in dispute; the staff, on the other hand, held that the inquiry was only for the information of the governors with whom the final decision must rest. The board broke off negotiations in an abrupt manner which, if they were sincere in their desire to effect some basis of settlement, is inexplicable. It is hoped that the governors at the ensuing meeting—in view of what we have stated as to the grants from the Metropolitan Hospital Sunday Fund and the Prince of Wales's Hospital Fund—will insist on some explanation of the delay for which the board were responsible in replying to the proposals of the staff.

We now come to the latest phase of the controversy—the publication in the *Times* of March 11th of a letter signed by the secretary-director of the hospital giving his account of the controversy and intimating that there would be a meeting of governors on March 23rd. Mr. BURFORD RAWLINGS'S letters have been many and remarkable and his last letter is not the least remarkable among them. The statement that "the attitude of the staff towards the proposed inquiry and certain statements put forward by, or on behalf of them, appear to show that the staff would be quite ready to abandon the charges if only they were granted the demand for representation, which the charges were intended to enforce," must, to anyone who has followed the controversy, carry its own contradiction on the face of it. It is to be hoped that the staff will insist on the production of proof of these alleged statements. Mr. RAWLINGS attributes the present financial embarrassment of the hospital to the action of the medical staff. A consideration of the position which the Metropolitan Hospital Sunday Fund and the Prince of Wales's Hospital Fund have assumed in regard to the controversy, and of the delays which the board have interposed, will clearly show who is responsible for the crippled finances of the hospital and the impending restriction of its usefulness. Not only on behalf of the staff of a particular hospital, but in the name of the medical profession as a whole, we indignantly repudiate the insinuation, also contained in this letter, that medical influence in hospital administration can possibly impair the usefulness of the charity or detract from its character of benevolence. A hospital exists primarily for the cure of disease and the relief of suffering. Those in whose hands these high functions rest are not the Board of Management alone or the medical staff alone. The two bodies share the duties and responsibilities. The medical staff can have only one object in desiring proper representation upon the board—viz., to strengthen the administration in order that its power of dealing with disease and suffering may be increased and extended. And we would point out how misleading is the suggestion made in this letter that the administration of the National Hospital for the Paralysed and Epileptic is similar to that which obtains in other institutions. The National Hospital for the Paralysed and Epileptic is neither a large nor an ancient charity. It cannot be compared, for instance, with St. Bartholomew's Hospital. It is a special hospital and should be compared, therefore, in its administration with other special hospitals—e.g., the Brompton Consumption Hospital, the Children's Hospital, Great Ormond-street, or the Royal London Ophthalmic Hospital. In all of these there is an ample representation of the staff on the Board of Management. Indeed at Brompton every member of the staff is *ex officio* a member of the board. Medical influence in its councils could not be stronger, and yet it has never been suggested that it is pernicious. The statement in the letter of the secretary-director of the National Hospital that the influence of a medical staff becomes dangerous in precise proportion to the eminence of the

medical staff is too preposterous even to be considered. We trust that the governors will sweep away all quibbles and side issues, will insist on a full and impartial inquiry, and will finally intrust the medical staff with that voice in the administration of the hospital to which their eminent services more than entitle them and which the good of the hospital demands.

Annotations.

"Ne quid nimis."

REGULATIONS FOR MILK AND CREAM.

THE Departmental Committee appointed by the Board of Agriculture to inquire into, and to report upon, the desirability of making regulations with regard to the sale of milk and cream have just published a very interesting document containing their recommendations. Despite the opinion expressed by many that the problem of controlling the milk trade was one which well-nigh defied perfect solution, yet the overwhelming body of evidence is in favour of the view that the setting up of some statutory limits for milk is necessary. Unless it be held that the Food and Drugs Acts are as regards the sale of milk unnecessary—a view actually taken by not a few—it is difficult to escape from the conclusion that some limits should be fixed in order to make analysis a criterion as to the quality of the milk. It has been proposed that seasonal limits might be adopted in order that no injustice should be done, for it is true that the quality of normal milk varies at different seasons of the year. The adoption, however, of a set of minimal limits which should be applicable at all times and under all conditions to milk produced for consumption, is the course which has commended itself to the committee. Ultimately, after a careful survey of the evidence, the committee are disposed to conclude that the milk produced for sale in this country contains on an average from 12·5 to 12·8 per cent. of solids, comprising from 3·7 to 4 per cent. of fat. Any milk, therefore, the committee consider, in which the total solids are less than 12 per cent. should be further inquired into, and if it should be then found that the amount of butter-fat is less than 3·25 per cent. a presumption would be raised that it had been mixed with separated milk or water, or that some of its original fat had been abstracted; if the solids, not fat, are found to be lower than 8·5 per cent. a presumption that it had been mixed with water would arise. In regard to cream the committee are of opinion that the weight of evidence was not favourable to the establishment of official limits of fat; nor does it appear that any substantial difficulty arises in selling cream in different qualities, at corresponding prices, to meet the requirements of the public. It is very properly considered, however, that steps should be taken to prevent the artificial thickening of cream by the addition of gelatin or other substances. The recommendations of the committee also relate to the composition of separated milk and condensed milk, in regard to the quality of which similar recommendations as to limits are laid down. The report is signed by all the members of the committee except one who, being unable to give his assent to the principal recommendations, embodies his own conclusions in a separate report. Mr. Barham in this report is in favour of the adoption of a seasonal standard. He takes 3 per cent. of fat as fairly representing, with 11·75 per cent. total solids, the milk during the months from July to February inclusive and the same amount of total solids with 2·75 per cent. of fat for the months from March to June inclusive. In any case he regards the milk as deficient in its normal constituents when the total solids are less than 11·75 per cent. and the non-fatty solids than 8·5 per cent. Mr. Farmer signs the report subject to a reservation. He also agrees to seasonal limits and objects to the suggested limit of 3·25 per cent. of fat for the whole year. We feel sure that it will be ultimately shown that legislation can only be satisfactorily applied towards upholding the supply of milk of good quality by the adoption of one limit for all seasons of the year. Moreover, since it was announced some months ago that the limit adopted at the Government laboratory was 3 per cent. of fat the quality of the London milk-supply has very materially improved, as shown by the latest analytical returns.

THE UNIVERSITY OF LONDON.

AT a meeting of the Faculty of Medicine at the University of London on Friday, March 8th, the following reference from the Senate was discussed and passed:—

That it be referred to the Faculty of Medicine to consider and report to the Senate as to the manner in which it may best carry out the duty stated in the following paragraph of Section 80 of the statutes of the University—viz.: the Senate shall use its best endeavours, whenever practicable, to secure common courses of instruction for internal medical students in the preliminary and intermediate portion of their studies under appointed or recognised teachers at one or more centres.

A committee was appointed to report, consisting of the members of the Senate elected by the Faculty of Medicine, the professors of anatomy and physiology who are members of the faculty, and two teachers from each of the medical schools, who are also members of the faculty. Only one-fourth of the members of the faculty were present at this important meeting. So far as the intermediate portion of the medical studies is concerned, we think that, although the study of physiology may be centralised or concentrated, it will be obviously impossible to carry out this in the case of anatomy. The Commissioners who drew up the statutes cannot have any knowledge of the teaching and restrictions of practical anatomy. In preliminary science concentration is very advisable, but even here the University must not lose sight of the fact that the large majority of medical students merely study for the first examination of the conjoint board, and the schools will scarcely hand these scholars over to a centralising board as suggested by the Commissioners who have drawn up the statutes. The whole plan of centralisation is unadvisable, as then there will be no competition among the teachers, and they will have no touch whatever with the necessities of medical teaching, but will become a pure scientific bureaucracy. Moreover, there are many excellent laboratories in the London medical schools which are admirably fitted for scientific instruction and are supervised by as good teachers as are likely to be found in any single institution.

LORD ROSEBERY AND COLONEL LOCKWOOD ON THE LONDON WATER-SUPPLY.

COLONEL LOCKWOOD, M.P., when he was giving evidence before Lord Llandaff's Commission described himself as being "quite a chicken" amongst water company directors. If we may be permitted to carry on the pleasing metaphor of the honourable and gallant gentleman we will congratulate him on being now a fully fledged fighting-cock amongst directors, for he has challenged Lord Rosebery to inspect the excellent water-fittings which the companies so kindly wished their customers to put in at their own expense. It does not appear from the correspondence which was published in the *Times* that Lord Rosebery expressed any desire to see the water-fittings, but his letter seems to show that he is not very thoroughly acquainted with the details of the

metropolitan water-supply or of the absurdity of the plan proposed by the London County Council to purchase the companies' undertakings and to resell parts of them to the extra-metropolitan authorities. Nor can the London County Council be properly looked upon as the metropolitan authority for London, as Lord Rosebery implies. The metropolitan authorities are the Cities and Boroughs and the County of London itself forms but a small part of "Water London."

THE BEER-POISONING EPIDEMIC.

AFTER the hearing of considerable evidence at the inquest held at Liverpool on the body of a woman who died in December last, presumably from the effects of poisoning by beer, the jury have arrived at the following verdict: "That the cause of death was arsenical poisoning through drinking beer; that Bostock's directors were not culpably negligent, but were to blame for not notifying to the makers of the acid that it was required for food purposes; that Nicholson's were not culpably liable, but displayed extreme indifference; that Mr. Cook, the works chemist, was neglectful but not culpably so; and that Dr. Morris, the consulting chemist, displayed great carelessness in his supervision of Cook's discharge of his duties." This verdict is accompanied by the following rider: "We are of opinion that better supervision should be exercised over the quality of the liquors supplied in licensed houses." The inquiry lasted 11 days and the evidence was striking in showing how urgently further legislation is needed in regard to the supervision and control of the processes of manufacture of articles used in and for the preparation of human food and drink.

THE RECENT EPIDEMIC OF PLAGUE IN SYDNEY.

THE report on the outbreak of plague at Sydney during 1900 made to the Government of New South Wales by the chief medical officer of the Government and President of the Board of Health (Dr. J. Ashburton Thompson) has just been issued. The report commences with what may be called a despatch stating the names and services of the permanent and temporary members of the Department of Public Health, who both worked zealously during the epidemic and furnished the various details upon which the report is founded. Between Jan. 19th and August 9th there were 303 cases, but of these only 262 are referred to in the clinical descriptions embodied in the report, for 39 patients died before notification or so soon after that no clinical observations were possible; while two others lay ill at a distance from Sydney. Prodromal symptoms were hardly ever observed, but, as a rule within a period of from one to 12 hours, the patient passed from a state of apparent health to one of severe illness. Rigors, headache, vomiting, flushing of the face, and suffusion of the eyes were almost constant symptoms, while the temperature ranged from 100° to 102° F. In general the bowels were constipated, but diarrhœa sometimes occurred and was a bad symptom. In some cases even at this early stage the glands were painful. During part of the first and the whole of the second day the symptoms deepened in gravity, coma, delirium, and sleeplessness supervening, while the temperature rose to between 101° and 105°. This condition was maintained more or less up to the fifth or even the sixth day. Diarrhœa and external hæmorrhages occurred in some cases and were of grave import. The bubo increased rapidly. During the sixth, seventh, and eighth days the disease began to decline and improvement in favourable cases was rapid. On the tenth day convalescence began and was accompanied by suppuration of the bubo. The above represents the ordinary course of the disease, but in some cases patients simply complained of feeling ill and died quite unexpectedly with no definite symptoms. The post-mortem appearances were those of a profound blood change. The bacillus pestis was easily obtained from buboes or viscera and as easily cultivated. The form which the disease took was almost exclusively bubonic, but 17 cases were septicæmic and one was apparently pneumonic. As regards sex incidence nearly four times as many males as females were attacked; as to age incidence more than half the cases occurred in persons between 15 and 35 years of age. The gross fatality was 34 per cent. Only 10 of the patients were Chinese, a race in which plague fatality is very high (as a rule 80 per cent.), and of these 10 Chinese eight died. If these be deducted the fatality is reduced among whites to 32·4 per cent. For protective inoculation Haffkine's serum was employed and in all 10,700 persons were inoculated, including the members of the various staffs. No illness occurred among the latter except in one case—that of a temporary scavenger who escaped inoculation. His case was slight and he presumably infected himself from dressings. Among the inoculated public 13 cases occurred, all of which were very slight. One fatal case was that of a boy whose relatives declared that he had been inoculated two months before his attack, but proof of inoculation was not forthcoming. For treatment Yersin-Roux serum was used in 71 cases, and the report, while not coming to any definite conclusion, states that the serum has antitoxic powers but can hardly be relied upon as a very active curative agent at present. Rigid administrative measures were taken, cleansing of dirty wharves, houses, and areas was carried out, patients and "contacts" were strictly isolated both from the general public and from one another, and a rat-destroying campaign was entered on. Section VI. of the report is most interesting and deals with the origin and mode of spread. Shortly, the disease is shown to have not been "catching." It was not communicated in any important degree by clothing, merchandise, or excreta. The epidemic was caused by communication of the infection from rats to man, and the medium of infection is presumed to have been fleas. Section VII., which deals with prevention, is summed up in the following paragraph: "Thus the best and the only attainable defence against epidemic plague lies in the removal of dangerous conditions which for the most part could not occur under good municipal management, even of the elementary processes of inspection, record, and scavenging." The appendices contain, amongst other subjects, a full bacteriological report, together with experimental observations on the modes of infection, and a clinical and pathological report. There are also spot maps showing the probable places of infection and the distribution of the disease. The report, of which we have given but the outline, is exceedingly interesting and deserves careful study.

THE WORK AND THE EXPENDITURE OF THE METROPOLITAN ASYLUMS BOARD.

AT a recent meeting of the Islington Guardians Mr. Sanders, one of the representatives of Islington at the Metropolitan Asylums Board, reported that they had only 3192 patients in their hospitals. This number is 555 less than in 1900 and 1107 less than in 1899. He was reminded by his fellow guardians that, nevertheless, the expenses increase. It is in the nature of the case that the patients of these hospitals should fluctuate much in numbers, but the steady increase of the expenditure is remarkable. The fact was brought out by the chairman of the Financial Committee of the Metropolitan Asylums Board at their meeting on Saturday, March 9th, who remarked that every class of institution except the training-ship, and every group of expenditure except maintenance charges, showed an increase. The net increase in the current expenditure for 1899 was £47,000 and for the year 1900 it was £63,000.

Decrease in the number of hospital patients was in no way followed by decrease in expenditure; the daily average number of infectious patients was 6 per cent. less, and the total current expenditure was 10·5 per cent. more, than in the previous year. The ambulance service spent £2487 more, yet removed 8328 fewer patients. The number of patients decreased 11·53 per cent.; the number of the staff increased 0·68 per cent. Such a state of affairs is difficult to understand and is likely to go on until the whole administration of the Board is subjected to that criticism which alone checks the automatic increase of expenditure in bodies who have to make precepts of payment to other bodies and who are not directly amenable to public opinion. One curious and questionable step the Board have taken to reduce their expenditure, and that is to terminate the insurance policies on their buildings on the ground that they have paid £13,878 5*s.* 2*d.* and only received back £6110 13*s.* 7*d.* A much wiser thing in the way of curtailing expenditure to be credited to the Board is the defeat of a motion for the provision of hospitals for measles. Such a provision would add enormously to the expenditure of the Board, while it would be very unlikely to curtail the number of epidemics of measles and would possibly add to the intensity of the disease.

THE LIMIT OF ALCOHOLIC STRENGTH OF NATURAL WINES.

AN important point in regard to the amount of alcohol which may be normally developed in a natural wine is raised in a letter which appears in our correspondence columns this week. The discussion of the question, as will be seen, had its origin in the results obtained in THE LANCET Laboratory in regard to the strength of certain South Australian wines under examination. The view of our correspondent would appear to be borne out by the report of a Commission appointed to inquire into the alcoholic strength of South Australian wines by the Colonial Government. According to this report a great number of natural wines produced in South Australia showed an alcoholic strength of as much as 38·5 per cent. of proof spirit, which is equal to 15·5 absolute alcohol by weight or 19·18 per cent. by volume. Further instances, according to this report, show strengths of 38·7 per cent. and 42·57 per cent. proof spirit, which are equal to 18 per cent. and 19·83 per cent. by weight of absolute alcohol respectively. The assumption is that the climate of South Australia possesses such ripening qualities as to produce a grape juice exceedingly rich in sugar. As a matter of fact, the grape juice shows a specific gravity far exceeding that of grape juices produced in other wine-producing countries and especially those of Europe. Of course, it does not follow that because grape juice is exceptionally rich in sugar it will necessarily produce a corresponding amount of spirit, for whatever the limit may be there is undoubtedly a point at which natural fermentation will cease when the alcoholic strength is such as to prevent the further growth of the yeast organisms and therefore the further development of spirit. It will be found that biologists, chemists, and others have generally laid down that the amount of alcohol produced in a normal fermentation does not usually exceed 12 per cent. by weight, which is equivalent to about 26 per cent. of proof spirit. Accordingly, when a wine is found to contain alcohol in excess of this amount a suspicion is entertained that it has been fortified or brandied. Thus, in dealing with certain specimens of colonial wine Dr. A. Dupré and Dr. J. L. W. Thudichum, in their work on "The Origin, Nature, and Use of Wine," report the strengths respectively of 29·4 per cent. and 27·2 per cent. of proof spirit. They conclude in the former case that the wine "consequently was brandied" and in the latter that it "was therefore alcoholised." Dr. Percy Frankland, in Thorpe's "Dictionary of Applied Chemistry," page 117, writes also: "When the proportion of alcohol produced amounts to 12 per cent. the further growth of the yeast is prevented, and with 14 per cent. (30·26 per cent. proof spirit) fermentation ceases altogether." Mr. Wynter Blyth, in his work on "Foods," page 480, also writes: "Natural wines contain as a minimum 6 per cent. (13·11 proof spirit) and as a maximum a little over 12 per cent. of absolute alcohol by weight (26 per cent. proof spirit). Even under favourable conditions scarcely more than 15 per cent. of alcohol (32·38 per cent. proof spirit) can be obtained by fermentation." Again, Professor Fischer of the University of Leipsic writes in his recent book on "The Structure and Functions of Bacteria," on page 132, that "as soon as all the sugar in a fermenting fluid is used up the process ceases, as it does also in any case when the alcohol has reached 12 or 14 per cent." Again, von Richter, in his "Organic Chemistry," page 120, says: "The yeast germs cannot grow in liquids containing 14 per cent. of alcohol." Dr. Dupré and Dr. Thudichum also say in their work already alluded to: "But even a wine of 26·5 degrees of proof spirit is upon the limits of what is chemically possible, because fermentation even under the most favourable conditions is invariably arrested by the presence of about 15 per cent. of alcohol." Lastly, Dr. Hassall came to a similar conclusion when he stated in connexion with the work of THE LANCET Analytical Commission that "even if the must were rich enough to permit of the formation of a higher amount of alcohol, it could not do so since fermentation is stopped in any liquid containing 15 per cent. of absolute alcohol by volume, equal to 26 66 per cent. of proof spirit." There seems, therefore, to be a consensus of opinion amongst biologists, chemists, and others that the utmost limit of normal alcoholic strength in a natural wine is 26·66 per cent. of proof spirit. And upon this figure is founded the means of deciding whether a wine is fortified or not. Yet according to the returns published by a Commission in South Australia a natural wine produced in that country may contain as much as 42·57 per cent. of proof spirit, or, according to our correspondent, 44·52 per cent. Wherefore it would appear that the generally accepted method of adjudging the character of a wine as regards whether or not it contains added alcohol is untrustworthy and its adoption if persisted in is calculated to do an injustice.

PALUDISM AS A CAUSE OF GENERAL PARALYSIS.

IN the *Revue de Médecine* (November, 1900) Dr. E. Marandon de Montyel, medical superintendent of the Ville-Evrard Asylum, has called attention to the little known but important fact that paludism must be reckoned a cause of the peculiar cerebral degeneration which constitutes general paralysis of the insane. After referring to the classical case observed by Lemoine and Chaumier of a workman, aged 38 years, who was free from syphilitic or alcoholic taint, but who nevertheless developed general paralysis of the insane as the result of malarial infection contracted at the age of 23 years and of repeated attacks of ague since then, it is pointed out that the only thing lacking to complete the chain of proof was the absence of a necropsy after the patient had died with all the clinical signs and symptoms of general paralysis. It was also pointed out that in this case there was an absence of neuropathic or hereditary taint, and Lemoine and Chaumier concluded that the toxic action of the malarial poison was the cause of the disease. From the study of eight cases of paludism followed by symptoms of general paralysis or pseudo-general paralysis de Montyel concludes that the following may be accepted:—1. Some of the cases result

from chronic and the others from acute paludism; in the present article there are four cases of each kind. 2. In four cases of acute paludism three showed clearly that the malarial poison could produce, after a brief delay, a progressive general paralysis of cerebral functions ending in death, while in one case the symptoms were those of pseudo-general paralysis and were both non-progressive and curable. In all the above four cases it was probable from their histories that some form of neuropathic predisposition existed. 3. Chronic paludism was capable of producing a true progressive and fatal peri-encephalitis in predisposed subjects. Of four cases of chronic paludism three incontestably showed this. Two of these three showed a syphilitic taint and a predisposition to cerebral congestion. In the fourth case, however, there was no such taint and careful examination disclosed that chronic paludism was the sole discoverable cause. This case was very remarkable and was as follows. The patient, a man, 40 years of age, single, a shoemaker, was free from hereditary taint, whether neuropathic, congestive, or vesanic, and devoid of physical or mental stigmata of degeneracy. He was of good physique, well-developed and intelligent in mind, of temperate habits, and free from syphilis and from cranial injury. 16 years prior to admission as a patient at the Ville-Evrard Asylum he lived in a malarial district in Algiers and contracted intermittent fever of the quotidian type. In spite of all treatment this recurred every summer during the months of July and August, and he suffered also from neuralgias of the face and head. He remained single, and till the age of 39 was of normal mental condition. He then (at the beginning in 1892) began to suffer from weakening of his mental powers and a fear of becoming mad. He became gloomy and preoccupied, suffered with his head, and developed insomnia. He complained of loss of memory and of lack of power of the association of ideas. In the summer of 1892 he had a recurrence of malarial fever, the second attack of which was followed by an epileptiform cerebral seizure, from which he rallied only to pass into confirmed and progressive general paralysis. The clinical symptoms with regard to speech, the pupils, and the facial muscles were typical of general paralysis, and he developed both grandiose and hypochondriacal delusions. He died within 11 months, and the necropsy showed the usual lesions, both macroscopic and microscopic, found in the brains of general paralytics.

THE BRISTOL CRUELTY CASE.

MR. JUSTICE DAY has sentenced to 15 years' and five years' penal servitude respectively a man and woman cohabiting at Bristol and convicted before him of attempting to murder the child of the man, a boy aged eleven years. We need not go into the circumstances of revolting and callous cruelty in which they endeavoured to compass the death of their victim except to say that they richly deserved their sentences. We are more concerned to point out, as the public press of this country has pointed out again and again, that as long as parents of the more or less impecunious class are permitted to insure their children for sums that will reward them handsomely for their children's deaths, so long will child murder be profitable, while we need hardly add that child murder can be and is committed in many more cases than those which are investigated at coroners' inquests and at assizes. The Bristol convicts relied partly, at all events, upon starvation, so that when they were detected there was a half-starved child who could be produced, and his starvation proved to demonstration. In part also they relied on exposure to cold, causing him to live in a room with the window open and without a fire in winter. Exposure of a child, less hardy, perhaps, and younger than the boy at Bristol, to wet or damp, to cold and to draughts, will soon set up a condition of things which, duly developed, will become serious for the child. If the medical man be not summoned too soon the child may then die with all the protection afforded by medical attendance and the burial certificate, which is all that the law requires; for the medical man is not a detective, nor is he charged with any inquiry into all that happened before he was called in and as to what produced the symptoms that he found awaiting him. With regard to insurance, the boy at Bristol was insured with one company alone for £25 and there was mention of insurance effected or attempted with others, while both man and woman had boasted of what they would do with the money that would accrue when the poor little fellow was dead. It may be right that parents should be able to recoup themselves for the expense to which the death of a child may put them, and many will say that if the insurance companies were permitted to pay to parents such a sum as they were proved to have expended on medical attendance and funeral expenses for a deceased child no great harm would result from this arrangement. Perhaps it would not, for in such circumstances few or none of the parents who are capable of hastening the deaths of their offspring would trouble to insure them. They would still have a motive for destroying them—namely, the saving of the expense that small children necessarily cause to their fathers and mothers. We cannot prevent child murder from ever occurring, but we can put difficulties in the way of its being committed with impunity by improving our regulations for the certification and registration of deaths, and we can abolish some part of the profits which form the motive of its committal. The profits of the companies which make money by insuring children ought not to be considered in such a connexion; they are not of the class of vested rights which deserve protection.

TREATMENT OF THE COCAINE HABIT BY COMPLETE WITHDRAWAL OF THE DRUG.

DR. G. W. NORRIS has published in the *Philadelphia Medical Journal* of Feb. 9th last a case of the cocaine habit of 10 months' duration treated by complete and immediate withdrawal of the drug. The case was that of a dentist, aged 30 years, who 10 months prior to admission to the Pennsylvania Hospital had suffered severely from hæmorrhoids, for the relief of which he had used cocaine locally as a rectal injection. Relief of pain was obtained, but he nevertheless continued to take the drug in daily increasing doses and after some time by the hypodermic method, on account of its stimulating and exhilarating effect. At the time of admission to hospital his daily dose was 16 grains of cocaine hydrochlorate. One result of the cocaine habit was that time seemed to him to pass very rapidly, minutes seeming like seconds, and he experienced a continuous, voracious, insatiable appetite. His energy and his application to work, however, declined, and he developed a tendency to procrastination. Insomnia was constant unless he took cocaine, upon the injection of which in small doses he slept well for one or two hours, when its repetition was necessitated. Single large doses kept him awake. For several months he had been troubled with hallucinations of hearing and he avoided street-cars and public gatherings because in such places he heard voices accusing him of being a "cocaine fiend." At night he would wander from room to room in his efforts to escape the voices which he heard talking about him, calling out, "Look, he's going to take another!" and, while reasoning with himself on the subjective character of his troubles, yet he was impelled by their vividness to flee from them as from realities. During the week prior to admission he had had syncopal attacks whenever injections were omitted for more than two hours. The treatment adopted

after his admission to hospital consisted of the complete withdrawal of the drug and the administration of one-thirtieth of a grain of strychnine sulphate every fourth hour and of 20 grains of sulphonal every two hours. On the first night he slept fairly well; on the second night he required no hypnotic whatever and only the medication with strychnine was continued. He rapidly became well and in a few days volunteered the statement that he felt like his former self for the first time for many months and that time once more seemed real to him. He complained of no craving for the drug and was discharged from hospital a week after admission as cured, though advised to keep himself under medical surveillance for a longer time.

CHELSEA CLINICAL SOCIETY.

THE annual clinical debate of the Chelsea Clinical Society was commenced on March 12th, at the Jenner Institute of Preventive Medicine, under the presidency of Dr. William Ewart. The subject for debate was, "The Clinical and Pathological Relations of the Chronic Rheumatic and Rheumatoid Affections to Acute Infective Rheumatism," and it was introduced by Dr. Archibald Garrod, who read a paper which is published in full in the present issue of THE LANCET. Dr. Garrod was followed by Dr. F. J. Poynton, who contributed a joint communication from himself and Dr. Alexander Paine. An interesting evening was closed by contributions from Mr. N. C. Macnamara and Dr. C. O. Hawthorne. Our report of the discussion is deferred until next week.

THE TREATMENT OF TUBERCULOUS PERITONITIS.

DR. BURNEY YEO'S paper on this subject which we publish in another column is of unusual interest. Tuberculous peritonitis is a condition fairly frequently met with, but the treatment of the condition has always been unsatisfactory. Many authorities have taken most despondent views as to the possibility of cure. Many facts connected with this disease, however, suggest that peritoneal tubercle is not possessed of great activity or powers of resistance, and that its natural tendency to obsolescence is readily facilitated by what appear to be but very trifling disturbances of the conditions under which it is developing. Dr. Yeo refers to the results of the surgical treatment of tuberculous peritonitis by which very successful results have been achieved, especially in the early stage and when there is always more or less ascitic fluid in the peritoneal cavity. A practitioner would naturally prefer to dispense with operative procedure if possible, although if he considered it the only means of cure he would certainly recommend it. Dr. Yeo draws attention to a method of treatment which he has tried with success—namely, the application to the abdomen of a liniment containing iodoform or iodine, at the same time administering internally a pill containing iodoform and creasote. He believes that when iodoform is rubbed into the skin of the abdomen in a young person it probably rapidly enters the blood and is, if regularly applied, continuously eliminated in the secretions, including the secretions into the serous cavities, and as these do not pass out of the body as the secretion of the kidney does they must in course of time become richly charged with iodine compounds, at any rate sufficiently so to act as antitoxin to the tubercle toxin or as anti-bacterial to the bacilli. This suggestion is a plausible one and this method of treatment will doubtless receive further and more extended trial. It is a fatal mistake to extol any therapeutic measure that has not passed the ordeal of extended experience, but we shall await with interest the reports of Dr. Burney Yeo and other observers who may adopt the line of treatment suggested by the above theory. It might be found advantageous to use some of those preparations recently introduced in which iodine is combined with a hydrocarbon basis by means of which, it is stated, the drug can be easily applied and is very readily absorbed.

THE INTERNATIONAL CATALOGUE OF SCIENTIFIC LITERATURE.

IN THE LANCET of March 9th, p. 736, will be found a letter from Dr. W. D. Halliburton dealing with this important matter. It will be seen by his letter that indexing and cataloguing commenced with all papers published on and after Jan. 1st of the present year and that there will be two indices—i.e., an index of authors and a subject index. The participating nations are to be severally responsible for the indexing of papers published in their own country, and a British bureau has already been formed for Great Britain and Ireland. There is in addition a central bureau to collect, coördinate, and publish the labours of the various national bureaus. Dr. Halliburton draws special attention to certain of the more out-of-the-way subjects connected with medicine and asks workers in these fields to send copies of their papers to certain gentlemen responsible for the sections under which the subjects in question are included. We are glad to be able to congratulate the promoters of the scheme upon its active inception. The work will be arduous and never ending, but it has in it possibilities of the greatest value to science. The enormous growth during the past century of every department of science has necessitated a corresponding growth in scientific records, and to reduce this mass of matter to a form in which its details may be easily accessible will be no light task. But the benefits accruing to science from such work will be commensurate with the difficulties of the task, and we can only express our sincere wish for the success of the various committees.

SICKNESS AND MORTALITY IN THE NAVIES OF THE WORLD.

DR. J. A. PORTENGEN of the Netherlands navy has made a praiseworthy attempt to compare the published vital statistics of the navies of the world, but owing to the variant data upon which the returns are founded "the final results of the comparison," as Dr. Portengen himself observes, "are not very encouraging." In some instances—as, for example, in the Netherlands navy and also in our own—medical officers are required to include in their returns every case of illness or injury, no matter how slight or trivial; whereas in others, notably the navies of Italy and Japan, only serious diseases are reported. The term "invaliding," too, has different values in different countries, meaning permanent retirement of the individuals invalided in some, while in others it refers also to patients sent to their homes or elsewhere on account of temporary disability and liable to be recalled to duty on the expiration of their sick leave. The death-rate in our navy, as well as in that of Japan, comprises the mortality from all causes, but in the German navy the deaths occurring under medical treatment are alone included in it. During the decade referred to in the subjoined table the English mortality is swollen owing to the loss of the *Serpent* off the coast of Spain, of the *Victoria* in the Mediterranean, and of a boat's crew in China; but the German rate is exclusive of the losses in the *Adler*, the *Eber*, and the *Iltis*. In the vital returns of the Danish navy all pilots and dockyard artificers, together with their wives and families, are included in the totals, which are thus rendered useless for the purposes of comparison; while in the navies of Spain, Portugal, and Chili the statistical information that has been issued is too imperfect and fragmentary to be of service. Up to the present the naval authorities of France,

Sweden and Norway, Turkey, Greece, and Argentina have abstained from publishing any vital statistics whatever, but according to a notification recently issued by the French Marine Minister, M. de Lanessan, this reproach will shortly cease to be applicable with regard to the first-named country. It is much to be desired in the interests of sanitary science that the vital statistics of all naval Powers should be drawn up in a uniform manner, admitting of comparison and compilation.

Annual Sickness, Invaliding, and Mortality per 1000 of Strength in the Navies of the Undermentioned Countries during the Decade 1888–1897.

THE BIRMINGHAM CONSULTATIVE MEDICAL AND SURGICAL INSTITUTION.

DR. H. WARD IRVINE having announced his retirement from the post of consultant to the Birmingham Consultative Medical and Surgical Institution it remained for those interested in that body to consider what they should do next. An advance in this direction was made on March 7th, when the delegates of the Birmingham Hospital Saturday Fund met in the Council Chamber to receive and consider a report from their executive committee upon the situation. Mr. Alderman Cook was in the chair and was supported by Mr. Arthur Chamberlain and Mr. Councillor Nettlefold. The executive committee asked the delegates to agree that a successor to Dr. Irvine should be immediately secured. The chairman, in asking the meeting to approve the recommendation of the executive committee, pointed out that the institution during the nine months of its existence had been applied to by 400 persons. In the discussion which followed Mr. Morgan, a delegate, asked whether the successor to Dr. Irvine, if he felt that he could not rely upon his own judgment, could transfer the case to a consultant at a fixed charge of half a guinea. The chairman pointed out that they could not make such an arrangement. If the consultants offered to adopt this course it would be worthy of consideration, but they had never given any assent in that direction. Dr. E. D. Kirby pointed out that there had never been any necessity for the scheme, for any general practitioner could always get a consultation for his patient at any fee which he thought that the patient was able to pay. He moved that the report should be referred back. The amendment, however, was not seconded and the motion to accept the report was agreed to. Mr. Chamberlain then addressed the meeting. He said that they would not quarrel with the medical profession about fees. The medical officers would be offered either all that remained over of the fees after paying expenses or else a fixed salary. Instead of one medical man he suggested two, three, or even four, and he considered that the medical men might meet and see whether they could not agree upon some such scheme. So this is the latest idea of the Birmingham Consultative Medical and Surgical Institution—a medical aid society pure and simple, run by a lay committee. At present the institution is without a medical officer, so we will defer further comment until it obtains one.

CHILD LABOUR IN ITS HYGIENIC ASPECTS.

THE subject of child labour in its social and hygienic aspects has again recently come up for notice in an important statement which has been prepared by Mr. A. Spencer, chief officer of the Public Control Department of the London County Council. Reference was made in these columns two years ago to the report on the subject[1] laid before the London School Board and the observations made thereon by Dr. T. J. Macnamara. Shortly afterwards the subject was referred to in Parliament by Sir John Gorst, Vice-President of the Council of Education, in his speech on April 28th, 1899, when submitting the education estimates. In a powerful and sympathetic speech Sir John Gorst analysed the statistical returns and the records of the histories of board school boys and girls who among the poorer classes had often to toil for 50, 60, or 70 hours a week, before and after school hours, to earn a living; he described the hardships and sufferings of these overworked and underfed children in passages of genuine eloquence and pathos, and gave several illustrative cases with every detail of their squalid and wretched lives, "a picture which," as was observed by the newspaper press at the time, "would haunt the memory for many a day after." The School Board returns in their aggregate show that the total number of children entered as employed is 144,026. The occupations of these school children, mostly boys, include—hawking goods, 4235; agricultural work, 6115; boot and knife cleaning, &c., 10,636; selling newspapers, 15,182; working in shops and running errands, 76 173; needlework (girls), 4019; and domestic work (girls), 20 849. Of these schoolboys and schoolgirls 30,807 belong to the County of London, and work on an average from 40 to 70 hours a week, eight boys working between 71 and 80 hours, and two over 80 hours a week. The pay given to the children is generally very small. In 40,240 cases it was from 1*s.* to 2*s.* per week, in 47,273 cases it was between 6*d.* and 1*s.*, and in 17,084 cases it was under 6*d.* per week. In 104,600 cases out of a total of 144,000 the children were paid 2*s.* a week or less. The average wage of the total number was about 1*s.* a week, but in some cases meals, and occasionally clothes, were given. The report laid before the School Board in February, 1899, said: "Probably some (of the children) die as a direct result of the severity of the toil inflicted upon them in their early years, and certainly many more of them must become a permanent and heavy charge upon the public purse because of the physical incapacity resulting from the rigour of their early

[1] THE LANCET March 11th, 1899, p. 707.
[2] THE LANCET, May 13th, 1899, p. 1309.

experiences." The report adopted by the School Board two years ago considered that the restrictive powers were insufficient to prevent the over-employment of children. In our previous remarks[3] suggestions were made to the effect that county councils should frame by-laws "preventing the labour of, say, children under 12 years before 8 A.M. and after 8 P.M., and to limit the total number of hours per week to, say, not more than 20 hours." Mr. Spencer's report summarises a number of facts and points out that "the present system presses heavily on a large number of children, who, worked to exhaustion out of school hours, are rendered unfit to receive any real benefit from the educational system provided for them." This was one of the very points on which emphasis was laid in our previous comments, in which reference was also made to the signs of fatigue, restlessness, and incapacity which such overworked children were prone to exhibit in the schoolroom. Juvenile employment is regulated by law as regards some occupations—e.g., the stage and the circus. Liverpool and several other towns have done something to regulate juvenile employment, and it may be suggested that some alteration or addition might be made as regards municipal laws by the London County Council in order to deal with the problem in London. Such a reform would tend not only to the good of these unfortunate boys and girls, but would be fraught with benefit to the race in the next generation.

AMONG the new Knights of Grace of the Order of the Hospital of St. John of Jerusalem in England will be found Mr. Frederick Treves, Mr. A. D. Fripp, and Colonel G. S. Ryerson, M.D., their appointments being in recognition of their services to the troops in South Africa. Earl Roberts is also appointed to the Order, as are the Duke of Portland, Mr. Langman, Mr. Alfred Moseley, and Mr. Van Alen, all of whose work in connexion with the voluntary hospitals of the South African campaign is well known to our readers. Sir John Furley is promoted from Honorary Commander of the Order to Honorary Bailiff.

A TELEGRAM from W. F. Hely Hutchinson, Governor of the Cape of Good Hope, to Mr. Chamberlain, received at the Colonial Office on March 12th, 1901, states that the plague report for the week ending March 2nd was as follows:—Cases admitted, 24; deaths, 2; suspects, 4; contacts, 215. For the week ending March 9th the report was:—Cases admitted, 50; deaths, 18; suspects, 11; contacts, 299.

THE Council of the St. Andrews Graduates' Association are presenting an address expressive of condolence with the King on the death of her late Majesty Queen Victoria, and of loyalty and congratulation to His Majesty on his accession to the Throne. A similar loyal address has just been presented by the York Medical Society.

IT is proposed by his old friends, colleagues, and pupils at St. Bartholomew's Hospital to present Sir Thomas Smith with his portrait to commemorate his long connexion with the hospital. Subscriptions, which are limited to two guineas, are now being received by the treasurer of the fund, Mr. W. J. Walsham, 77, Harley-street.

THE Senatus of the University of Aberdeen are about to confer the honorary degree of LL.D. upon Professor Virchow of Berlin, Major Alfred W. Alcock, I.M.S., Superintendent of the Indian Museum, Calcutta, and Professor of Zoology in the Medical College of that city, and Dr. Angus Fraser of Aberdeen.

[3] THE LANCET, 1899, loc. cit.

HIS MAJESTY THE KING has graciously consented to continue to be patron of the Metropolitan Hospital, Kingsland-road, N.E. Mr. A. H. Allhusen, M.P., will preside at the festival dinner in aid of the funds of the hospital, to be held at the Whitehall Rooms on April 22nd next.

THE President, Vice-President, and Council of the Royal College of Surgeons in Ireland give notice that they will on Thursday, April 18th, elect a Professor of Surgery in the room of Sir William Stokes, deceased.

IT is announced that the King has been graciously pleased to appoint Sir Richard Douglas Powell, Bart., and Sir Thomas Barlow, Bart., to be Knight Commanders of the Royal Victorian Order.

DR. E. B. FORMAN, who sought re-election to represent North Hackney on the London County Council, but was unfortunately defeated, has, we are glad to see, been elected an alderman

SIR WILLIAM MAC CORMAC, Bart., K.C.V.O., P.R.C.S., is to receive the Honorary Freedom of the Barbers' Company on March 26th.

THE annual general meeting of the Medical Graduates' College and Polyclinic will be held on Tuesday, March 26th, at 5.30 P.M.

HIS MAJESTY THE KING has graciously consented to become the patron of King's College Hospital.

THE STATUS OF THE COUNTRY DOCTOR.[1]

BY HARRY ROBERTS.

THE commencement of a new century, though it is really but an artificially selected moment, is a convenient time for considering our position, for looking back, and for contemplating the future. All of us in this room have this much in common—that though we may not all live in little villages we may all be classed as "country doctors," and it is in this inclusive sense that I use the term. There can be no doubt that from one cause and another the power of country doctors has very much increased of late years. To a large extent the village doctor has nowadays often much of the influence formerly wielded by the parson, and this displacement is growing. This improved status is largely due to the fact that we are better educated than our predecessors, for culture generally, in the long run, means influence. Until lately the parson was usually the only educated man in his parish, and almost the only educated men in our ranks were the separate class of "physicians" who, although frequently ignorant of medicine, were almost invariably men of culture and wide knowledge as these were then accounted. It is from this fact that "physician" has conveyed to the popular mind a sense of learning and of status far beyond that given by the titles of "surgeon" and "medical practitioner."

But in spite of Solomon there are new things under the sun, and culture in the twentieth century means a different thing from culture in the eighteenth. An acquaintance with "smutty" Latin jokes is no longer sufficient to stamp a man as a gentleman and a man of learning. A familiarity with the works of Latin and Greek writers is now of little value as the stamp of the cultivated mind, knowledge bounded by words being at length recognised as pedantry instead of wisdom. To be acquainted with the thoughts and points of view of the great writers and dreamers of the world—modern as well as ancient—to have lived freely among

[1] A paper read before the West Penwith Medical Society on Feb. 13th, 1901.

people of many conditions, to have spent much time among the higher regions of existence,—these are some of the things which go to make up culture as we now understand the term.

Greater culture means greater tolerance, greater sympathy because fuller understanding, and as a result greater power and influence. No sane man would suggest that we should imitate the old physicians and replace our technical knowledge by ever-so-desirable a general wisdom; but if we are to be other than mere artisans and tradesmen it is essential that our knowledge should go somewhat beyond technique. A familiarity with the thoughts and philosophy of others, moreover, may help in suppressing that bumptious, pedantic assumption of wisdom which has ever been a characteristic of our profession. Even in the twelfth century we find the learned John of Salisbury saying of our professional ancestors of those days: "The professors of the theory of medicine are very communicative, they will tell you all they know, and, perhaps, out of their great kindness, a little more. From them you may learn the nature of all things, the causes of sickness and of health, how to banish the one and how to preserve the other; for they can do both at pleasure. They will describe to you minutely the origin, the beginning, the progress, and the cure of all diseases. In a word, when I hear them harangue, I am charmed. I think them not inferior to Mercury or Æsculapius, and almost persuade myself that they can raise the dead. There is only one thing that makes me hesitate. Their theories are as directly opposite to one another as light and darkness. When I reflect on this I am a little staggered. Two contradictory propositions cannot both be true."

The pomposity which has by nearly all lay critics from Molière to Sterne been associated with practitioners of medicine has been due to two main causes: firstly, our lack as a mass of any knowledge of the great book of wisdom outside our own chapter of medical and surgical handicraft; and secondly, our utter lack as a profession of any sense of humour. When a carpenter speaks to us of his work, or a gardener of his, we all feel able to follow his talk and to offer some criticism, but it so happens that the work of doctors is of such a nature that the lay public know nothing at all about it. Hence it has been that a surgeon or a physician, knowing his own trade and recognising that he stood head and shoulders above the public in that small subject, believed that he was indeed an Admirable Crichton. This belief was, of course, based on his ignorance of the fact that there are other sorts of wisdom, other branches of knowledge, than the one or two he had heard of. Our venerable priggishness, our owl-like expression, our grave shakings of head, our solemn hat and coat, to the gods and to anyone who knows on what shallow pretence these absurdities were based there was food for many hearty meals of laughter. Scarcely an English wit but has been stimulated by the study of one of our typical colleagues. We have in the past seemed to suggest a sort of glorified farcical cheesemonger as our ideal. Even now we are respectable or nothing. Strip us of our respectability and we cannot as a herd be told from a crowd of deacons of Little Bethel—the same smugness, the same lack of humour, the same worship of the sacred Mrs. Grundy, the same fear of overstepping the stupid little laws and customs which prevail among the ignorant middle classes of our country districts. For what does all this "caste" which forms the basis of country life amount to? Were it founded on differences of intellect or on differences in taste or temperament there might be supposed to be some weird reason for the snobby cliquism which is so familiar to all of us. But it is not so. A man or a woman may be possessed of the keenest intellect, the finest taste, and the most developed temperament, yet if he or his father happen to be engaged in a fatal occupation such as manual work or retail trade his position in an English village or provincial town is not one to covet. So fundamental is the British worship of respectability that a recent writer has suggested it as an explanation of the habit of our ancestors of painting their bodies with woad. This colouring was the badge of their gentility and it was their pride that even in battle, though their enemies might take away their clothes, they could never strip them of their respectability. Things are much the same to-day. The "lady" whose grandfather perhaps was the honest host of the village inn, but whose father washed out the stain of the bar-parlour by a life of idleness, would choose death rather than the soiling of her drawing-room carpet by the feet of one not blessed with so much blue-blood. The successful clerk who has worked or wheedled his way into a partnership would offer but a frigid reception to his colleagues of former years. Of such stuff is ordinary English middle-class society built up. Such are the "ladies" and "gentlemen" at whose shrine most of us bend the knee All this might be and should be altered. We, more than any other body of men, have power to do a very great deal to break down this childish and stupid game of "pretend we're real ladies and gentlemen," and so make country life less narrow and ignorant, more pleasant and cosmopolitan. We have this exceptional power on account of our intimate and peculiar relations with people of every class; and if we train our minds and hearts and regulate our lives with wisdom we may in time become the true directors of provincial social life. By proving that we at least are educated gentlemen, and that our lives are "*sans peur et sans reproche*," by showing further that we have no regard for the foolish little exclusiveness of provincial society, but that it merely excites our mirth, we may wield an enormous influence in the direction of overthrowing snobbery and bourgeoisdom. In a like manner we may do much to overthrow the equally ignorant and equally despicable form of pompousness—the pompousness of moral superiority which we commonly call "puritanism." At the bottom of the Anglo-Saxon heart is a firm conviction that all pleasure is sin, and this is a conviction which wants weeding out. In the Christian virtue of moral charity I think we compare favourably with the Christian church—but even in our ranks are plenty of moral prigs.

In a former paper which I read before this society I pointed out how essential to successful medical practice is deception. It is interesting to learn that this has always been more or less recognised. Thus about the year 1100 a very distinguished physician, Archimatthæus, wrote in his "The Instruction of the Physician": "Upon entering the house of his patient the physician should salute all with a grave and modest air, not exhibiting any eagerness, but seating himself to take breath he should praise the beauty of the situation, the good arrangement of the house, the generosity of the family; by this means he wins the good opinion of the household." On leaving he is to promise the patient a good recovery, but to tell the friends privately that there is much danger. "If he recover, your reputation is increased; if he succumb, people will not fail to remember that you foresaw the fatal termination of the disease." Even Bob Sawyer's trick of being called from church was very hackneyed in Dickens's time, for in the seventeenth century Gideon Harvey, one of the physicians to Charles II., wrote, that "the church door shall no sooner be opened but *ecce* Mr. Doctor, sitting in the most visible seat, Grave, Deaf, Dumb, and immoveable, as if an apoplexy of Devotion had seized him, out of which his Apothecary is to raise him by knocking at half-sermon at his pew-door to fetch him away post to a dying patient; by which means he draws the eyes of the whole congregation after him; but instead of going to a pretended House of Visitation they both drop into a cabaret, there to pass the fatigue of a forenoon Sunday. This knack of confederacy is to be repeated several Dominical days, until it hath made an impression on the people; that he is a man of importance, and of great Physick business." If we wish to convince, nowadays, we must be original and a little more subtle in our humbug.

There is one other feature in the popular picture of the doctor's character which should have a little consideration. When the humorists who have held our profession to ridicule have not been pointing to our pompousness they have usually had a shot at our zeal in pursuit of fees. As things are at present arranged, it is of course true that those who do useful work are right in seeking payment for the same. But there is a wise and a foolish course here. As far back as the twelfth century we find John of Salisbury writing of doctors that "they have only two maxims which they never violate; never mind the poor, never refuse money from the rich." As a matter of fact, no profession does such an amount of gratuitous work for the poor as does the medical profession, but for the most part we render our gratuitous services with such a bad grace that we get no personal satisfaction or public recognition. We are too apt to keep the fee ever before our eyes and on our lips, whereas the wise and pleasant way is surely to do our work smilingly as artists and as men of science, taking pride in our power and skill and regardless for the time being of the money payment we shall or shall not receive. By haggling

over money we degrade ourselves, lower the dignity of our profession, and in the end defeat our purpose and lower our status in the community. If we do our best for every patient who seeks our help, regardless of his wealth or quality or honesty, and content ourselves by merely sending out our quarterly or yearly bills, we may make a certain number of what money-grubbers would call bad debts, but our annual income will be as big as it would be if we adopted the dunning methods of the tradesman. We shall moreover, be spared the constant annoyance and irritation resulting from friction with our patients and our consciences.

On the whole, we may say that the position of the country doctor is better to-day than it has ever been, and that if we play the game skilfully and fairly, and take to heart the satires of the humorists, we may still further improve our status, our influence, and consequently our power of materially modifying the structure of provincial life. This is no despicable destiny.

Hayle.

THE ROYAL COMMISSION ON SOUTH AFRICAN HOSPITALS.

(Continued from p. 735.)

IV.

WE have commenced this series of articles with a summary of the report of the Royal Commission on South African Hospitals. We now proceed to deal with that report and with the evidence upon which it was drawn up. Nor shall we confine ourselves to these limits, but shall consider the whole question of the reorganisation of the Royal Army Medical Corps. Since we began this series of articles events have progressed with rapid strides. The debate on the Address afforded an opportunity which has not been neglected for seeking information from the Government as to its intended action in regard to the report of the Royal Commission on the South African Hospitals; and, as a reference to our Parliamentary Intelligence will show, this had the effect of eliciting a very important statement from the Secretary of State for War which has apparently materially altered the complexion of the case. Reform in the Royal Army Medical Corps has been promised.

The war in South Africa, and the causes which led to it, have, as everyone knows, given rise to a very voluminous literature; and even that portion of it which deals with the medical aspect of the campaign, especially in connexion with the South African Hospitals controversy, has already reached considerable dimensions. The latest additions to the subject have been the report and minutes of evidence of the Royal Commission with an appendix, and Mr. Burdett-Coutts's book on "The Sick and Wounded in South Africa" (which was published before the report), followed by his two very lengthy communications in which he reviews and animadverts upon the report of the Commission in a very trenchant and adversely critical way. The official report of the Commission consists of 71 folio pages, the minutes of evidence of 565 pages, and the appendix of 368 pages—to say nothing of reports of speeches in Parliament and of the published communications which have preceded and followed the appearance of the report itself. The amount of evidence afforded by such publications, which had to be considered, made it impossible to deal quickly as well as fairly with the question.

The subject is one which touches our national honour and interest and deeply concerns all classes of society. Our medical policy in time of war is a matter which should be kept altogether aloof from mere political considerations and party spirit, or class feeling and prejudices of any kind. We have always held and expressed the view that what is best for the public interest in general is best also for the medical profession whether in the army or out of it. We can only say on behalf of that profession that if an end can be put to these painful and recurring controversies, and if any measures of army medical reform can be devised for improving the organisation of the Royal Army Medical Corps, or for providing a better system of medical service in war than exists at the present time, so as to bring it more into harmony with all the requirements of the age in which we are living and those of modern warfare, there is no section of the community which will welcome or feel more grateful for these measures than the medical profession. We have carefully studied the reports and publications which have appeared and as the result of our labours we have left off with a conviction—which has been a growing one for some years past—that the time has come for re-considering the whole question, for enlarging our ideas and schemes, for putting matters upon a different and bigger platform than they now occupy, for, in short, introducing some new, bold, and broad measure of army medical reform while retaining all that is right and sound in principle or of proved value in the present system. The prevention of the diseases incidental to war, no less than the care of the sick and wounded, during a campaign, have always been, and, despite all we can do, will probably always continue to be, a very difficult problem for practical solution. What with the employment of highly mobile forces and the rapid marches and swift changes of position which modern methods of warfare necessitate on the one hand, and the growing feeling of patriotism and philanthropy and the advances in medical and sanitary science on the other hand, the problem is likely to be one of increasing difficulty and complexity rather than otherwise. But it must be boldly faced and deliberately considered. The creation of a British empire, the nature and size of armies, and the vast changes which have taken place in the science and art of war, have all tended to render the older methods of medical relief in war more or less of an anachronism. Viewed in this light we may regard the action of those who have brought about the appointment of a Royal Commission of inquiry into the care of the sick and wounded in the South African campaign as likely to be productive of much good instead of the reverse. Notwithstanding that the action initiated by Mr. Burdett-Coutts in his letter published in the *Times* of June 27th, 1900, and in some of his subsequent communications did not in form and course commend itself to our mind, we did not hesitate to declare that the main facts were sufficiently clear and, while waiting for a full explanation of the causes which led to them, we deplored their occurrence.

Since the publication of the report of the Royal Commission and of the strictures and criticisms which it has called forth, the question has, as we have said, made a great advance, for it has formed the subject of debates in which several speakers took part in both Houses of Parliament. Mr. Burdett-Coutts, who has, in his published letters, traversed the report from end to end, has asserted from his place in Parliament that the inquiry of the Commission has not been conducted in a way calculated to elicit the whole truth, and that the defects in the Army Medical Service have been concealed and buried in the lame and impotent conclusions of the report. We may fairly leave the Commission to take care of its report and to justify the course pursued and the conclusions at which it has arrived. Meanwhile the Secretary of State for War in a most important speech has made large admissions about the state of the Army Medical Service and has given such pledges in regard to it as should go a long way towards satisfying Mr. Burdett-Coutts. Mr. Brodrick has emphatically pledged himself to the introduction of a new and more satisfactory system which can only be brought about, he considers, by a drastic reform of the Army Medical Service; and Mr. Brodrick adds the promise that no effort shall be wanting, and that no past prejudices shall be allowed to intervene or to prevent the army from being given in the future an effective medical service. The machinery to be employed for the purpose, which will presumably be a strong Commission, has not yet been definitely settled, but we are promised that the advice and aid of the heads of the medical profession will be sought.

Turning now to the consideration of the report, we find that the zeal, devotion, and conduct of the medical officers generally who have taken part in this war have been admitted, and many of them have been highly commended. Not only will this be seen in the report itself, but more especially in the volume containing the Minutes of Evidence on the part of Lord Roberts, Mr. Burdett-Coutts (page 85), Mr A. Bowlby (pages 212–213) and of several others. We may here remark that all those who are specially interested in the subject should not rest content with simply reading the Report of the Commission. It was not until we had referred to the Minutes of Evidence that we were really enabled to appreciate the strength of the medical officers' position and the splendid work they had done, or to form

any adequate estimate of the great difficulties (which were for the most part of an unavoidable nature) that had to be overcome. Dipping into that volume and taking some of the evidence indiscriminately—such as that of Lord Roberts, Lord Kitchener, Mr. Watson Cheyne General Kelly-Kenny, Mr. A. Bowlby, Dr. W. Johnson, Major Bedford, Surgeon-General Wilson. Colonel E. W. D. Ward, and Surgeon-General Stevenson—will enable any dispassionate reader to form his own opinion on these points. We may consequently dismiss from consideration any question whether the Royal Army Medical Corps did their best in the circumstances. What the medical officers probably feel, however, is this: that all their laborious sacrifices and efforts have nevertheless ended in disappointment, and that they have somehow been very undeservedly identified with failure. One of the most noteworthy features of this war, it may be remarked, has been the adverse criticism to which almost all connected with it have been subjected. South Africa has proved the graveyard of several military reputations. Soldiers of repute have left this country only to realise, as a high Ministerial authority is stated to have remarked, that the South African campaign has been "one of miscalculations and disillusions." If the army medical service is to be re-organised under a fierce fire of criticism it will be at least the duty of all concerned to see that its newly-organised successor, which is presumably to appear phœnix-like out of its ashes, is something better and more complete. Nor do we despair of this being the outcome of the present situation. Towards this end we shall have much to say further on. Speaking generally of the report of the Royal Commission we may remark that it strikes us, as might have been expected under the presidency of Lord Justice Romer, as judicial in tone and eminently fair, although insufficiently vigorous, perhaps, in character. The Commission by its composite constitution was well fitted to take a reasonable, common-sense, and business-like view of the facts and evidence and of the military aspect of the situation; whereas much of the adverse criticism which the report has called forth from Mr. Burdett-Coutts is put from the advocate's point of view and with no little forensic skill. It is, moreover, advanced in defence and justification of a previously assumed position. After a brief account of the proceedings taken by the Commission the report leads off with some observations upon the evidence and the difficulties that had to be contended with in ascertaining the true condition of affairs, arising from various causes which are enumerated (page 3). It is, of course, always open to anyone to say—as, in fact, it is said—that owing to the operation of fear and other motives a very little knowledge of human nature, and especially of the military form of it, will lead to concealment of the truth. The Commissioners, however, it seems to us, took all the precautions which they could in this respect to arrive at just conclusions. Under the head of work done the Commissioners acknowledge that the Government and the military and medical authorities, both in England and South Africa, rendered every assistance and freely supplied all information that was called for (page 4).

Part II. of the report starts with some conclusions on various points of a general character having reference more especially to the war reaching a magnitude which the military and medical authorities had never anticipated that it would attain, to the hospital and ordinary provisions for the sick and wounded on active service in the field, and to some important points in connexion with the present campaign which require to be considered in the case of future wars. Under the headings of unit allowances and stationary and general hospitals a clear description of the hospital service is given. The evidence of the Director-General of the Army Medical Service and that of Lieutenant-Colonel Johnston and Major W. G. Macpherson, R.A.M.C., and others published in the volume of Minutes of Evidence may be usefully referred to in connexion with this part of the subject. The pivot of the whole field medical service system is to relieve the fighting force in front as much as possible of sick and wounded men by relegating them to the hospitals in rear. This is the direction which the sick and wounded must all eventually take, for only at the rear can they be provided for in the permanent hospitals—stationary and general. And here they should be in as well-equipped a hospital as at home. It is to be noted, the report tells us, that the South African campaign is the first in which stationary and general hospitals as now arranged have been made use of. Although there is no finality about anything, and there is plenty of room, no doubt, for developing and improving our methods of dealing with the sick and wounded in war, the principle of this present system is a sound one and has been generally adopted. There is no other method which leaves the general in command so free to follow out his plans untrammelled by the care of his wounded, and there is no better way of systematically stripping a battle-field of its wounded and securing prompt medical treatment, or of effecting the transit of the sick and wounded from the battle-field in front to the base, nor can the overcrowding of hospitals be better avoided. But its successful accomplishment pre-supposes that access to and from the fighting front to the base is fairly safe and free, that there is plenty of available transport, that the distance between the front and the base is not too great, and that the different kinds of hospitals are only used for the purposes for which they were intended; that, for instance, a lightly equipped mobile field hospital which has to move on with the force and is only intended for the *temporary* detention and treatment of its occupants shall not be diverted from its purpose and used as a permanent or general hospital for which it was never designed and to which it is not at all adapted. At page 5 of Part II. and again in Part III. of the report attention is called to the numerous complaints which arose from the fact that in the South African campaign field hospitals had to be used as fixed hospitals. But to resume. The view that the proper method of treating the sick and wounded is to transfer them to permanent hospitals at the rear as quickly as may be is generally regarded as a sound one. We beg our readers to bear this in mind and to carry it with them throughout their reading of everything connected with the history of this campaign. It supplies a key which opens the door to our comprehension of some of the positions in South Africa, especially, as it seems to us, in connexion with the events which followed Paardeberg. It serves to illustrate, in our opinion, that one of the great needs of modern war, and especially under such conditions as obtained in South Africa, which will have to be considered is that of a more active organisation, as far as possible, of stationary hospitals. The system of evacuation of the sick and wounded we have alluded to has been followed more or less in all wars, but it was most largely and systematically carried out by the Germans in the Franco-German war. In the case of the South African campaign 10 per cent. hospital accommodation was fixed upon, but that was, after all, a nominal rather than a real percentage. The custom of evacuation and the large and persistent relief of the hospitals by transport-ships proceeding to England were taken into account in making the calculation, and as a matter of fact an enormous number of invalids in the aggregate embarked for this country, with the effect of systematically freeing the hospitals in South Africa. The system has its disadvantages in requiring for complete efficiency to be worked in its integrity, and in causing some vicarious suffering in the transport and movement of some part of the wounded and sick for the benefit of the whole.

The ideal plan, which can only be in a measure carried out under exceptional conditions in small wars, is to carry the hospital to the wounded instead of the wounded to the hospital. But in proportion to the extent of area forming the theatre of war, the number and rapidity of the movements, the distance between the force operating in front of the base with its suitably equipped stationary and general hospitals, is the difficulty of getting the sick and wounded properly accommodated and treated. The sooner a campaign is over the better it is, of course, in every way for the army as a whole, but the harder it is for the medical service, the transport, and all supply departments. The aim should be, in order to guard against any temporary hitch, breakdown, or exceptional conditions—and the point has not been lost sight of in the report—to have, as we have said, the better equipped so-called stationary hospitals capable of being moved to the place where they are wanted; in other words, to create and to open out, where it is possible to do so, new temporary bases of operation. But where a force has to separate itself and to cut itself off from all means of communication, and where its commander is ignorant of what the morrow may bring forth, the military difficulties may obviously be insurmountable. The force can only carry the very lightest and most mobile hospitals with it, and it may altogether outmarch its

supplies. It is not difficult to apply this reasoning to the case of the campaign in South Africa; and it will form a very important subject for inquiry as to how far we can adjust the number, amount, scales, and patterns of the hospital and medical *matériel* to meet such contingencies in the future. We are of opinion that more might be done in this way.

"In the second edition of the Field Medical Service Manual for India, Section IX., General Hospitals, we read, for example, that general hospitals will be established in multiples of 50 beds, but in no case will the accommodation exceed 500 beds for a single hospital. Moreover, each general hospital with an army corps is a unit of 500 beds, but with a view of decentralising the duties it will be divided into sections of 100. It will be remembered that the use of the word "beds" is misleading, for the field hospitals, which are only intended to move with an advancing army and must therefore be very lightly equipped, have no beds, only a limited supply of stretchers. They have rapidly and frequently to evacuate their occupants. Nor have field hospitals any female nurses. (And here we may parenthetically remark as a matter of detail that where bedsteads do actually form part of any hospital equipment they might for various reasons be of less width than that of the regulation pattern, and that some carpenters with their tools would prove a very useful addition to the staffs of hospitals.) We quite agree with the Commissioners in their remarks about the present pattern of army ambulance wagons; they are altogether too heavy and too elaborate to be adapted to localities in which there are not fairly good roads. We agree also with what they say in this part of their report about the usefulness of the "E.P." Indian tent and the Ordnance Store tent for hospital purposes and with their suggestion as to the possible improvement of the hospital marquee ordinarily supplied to the British army; also in what they state about the increased employment of female nurses in *fixed* army hospitals supplemented by properly trained orderlies. The proper hospital training of military orderlies is a matter upon which we shall have something to say hereafter. We have italicised the word "fixed" because we do not consider that female nurses should accompany the fighting force to the front, and the same is, we believe, the opinion of all officers.

ANNIVERSARY DINNER OF THE MEDICAL SOCIETY OF LONDON.

THE Fellows of the Medical Society of London held their 128th anniversary dinner on March 8th at the Hôtel Métropole under the presidency of Mr. J. H. MORGAN. The interesting feature of the evening was the defence by Sir William Church of Sir William Mac Cormac and Mr. Frederick Treves from the inference to be drawn from Mr. Burdett-Coutts's remarks—namely, that on their return from South Africa they had misled the country by making laudatory speeches on the conduct of the medical departments in the campaign, when at the very time our hospitals and troops were, in the opinion of Mr. Burdett-Coutts, suffering from absolute neglect.

Sir WILLIAM CHURCH said that it was the first opportunity he had had of alluding to the Commission. He thought it would be within the recollection of most that the letters of Mr. Burdett-Coutts from South Africa had somewhat roused the attention of the country, and in those letters he had put forward that whilst members of the medical profession who had been in South Africa were making laudatory speeches on the conduct of the medical department concerned at that very time the hospitals and troops were suffering, in his opinion, from absolute neglect. Mr. Burdett-Coutts did not go so far as directly to attack Mr. Treves and Sir W. Mac Cormac for their reports which they presented to the country, but he seemed to wish the country to infer that they were seeking wilfully to mislead the country. No Commission ever undertook work with a feeling of more responsibility, no Commission ever worked so hard; it was felt that it was necessary for the country that their report should come before the country as quickly as possible. It had been stated that the Commission hurried through the work; they did hurry through their work, but they might say that though they hurried through it they did not do it badly. The Commission landed at Cape Town before 10 in the morning; all arrangements had to be made, their secretary had to negotiate for the room in which to hold meetings, and they had to fix what witnesses should be seen. In spite of all this the Commission opened at three in the afternoon of that day. For 34 days the Commission worked, Sundays and all, without cessation. He was only speaking the truth when he declared that during those 34 days they did not break off from the work of the Commission to see any sight or to see any object of interest; the only recreation which they had was that after taking evidence till about 12 30 on one day at Johannesburg they were invited to see something of the mines of the place. A few accepted that invitation, and that was the only thing in the shape of a sight or amusement that the Commissioners indulged in for the first 34 days in South Africa. Their report was divided into different heads, and the Commissioners were thoroughly convinced that up to the time and after the time that Sir William Mac Cormac and Mr. Treves left South Africa there was nothing to call in question. There had never been a campaign carried on by any country in which anything like such perfect arrangements for the sick and wounded had been in force. In the campaign up to a certain period, up to the time that the army left Modder river for the march to Bloemfontein, up to that time the care of the sick and wounded in that part of South Africa had been quite extraordinarily good, and the same, he thought, applied to the Natal side. But after the most remarkable march of Lord Roberts to Bloemfontein there was no object in concealing that the condition of affairs at Bloemfontein was most distressing and most sad. Those conditions, however, surely must always arise in war. He considered that the country was led or might have been led by the letters written from Bloemfontein to judge that these circumstances were quite avoidable, but without saying that everything was as well managed at Bloemfontein as possible, it must be conceded that a great deal of it was unavoidable if one judged fairly. Lord Roberts told them that for 14 days after he arrived at Bloemfontein he never knew whether he could feed his army or not. His first thought daily on waking was—Had he enough food to feed the army that day? For a great many more than 14 days the commissariat was never more than 12 hours ahead of the army's needs. There was no use attempting to conceal the fact that the condition of their sick was extremely distressing, but what would be the effect supposing suddenly in any one of our best managed hospitals three times the number of people were admitted than they had provision or attendance for? That was the case with the two general hospitals which were so much attacked at Bloemfontein. Now, without saying too much, it was regrettable that over these two hospitals on which the stress came it so happened the principal medical officers were less capable than were other principal medical officers whom the Commission came across. One of the two had afterwards to be removed and sent home and the other seemed not to be quite the right man in the right place. On this account the attack was made especially on Sir William Mac Cormac and Mr. Treves, as if they were wilfully misleading the country, and it was most unfair and unjust. The outbreak of fever at Bloemfontein that continued on the whole march to Pretoria was at the root of the trouble. There was no doubt that the army medical service, like the other parts of the army, was inadequate. All portions of the services were inadequate, no one had any idea of the magnitude of the task. There was no denying that many things were wanting, especially with regard to the hospitals. He would like to bear witness to the magnificent work which was done by a great number of the members of the Royal Army Medical Corps, not only the magnificent work which was done by them, but also the great powers of organisation which many of them showed. He would not mention any names, but in different places he came across men of great fitness who in extreme difficulties were obliged in important matters to exercise their own judgment entirely, to make their own arrangements, and perhaps to transgress the ordinary rules of the service. These men organised matters in such a way that the necessary suffering was, in his opinion, reduced very considerably.

Mr. TREVES delivered some remarks in a lighter vein and received a cordial reception, his happy allusion to the plain boiled sole so uniformly ordered by medical men as "that

small fish taken out of boiling water and placed in all its pallid nakedness before the sick" being one of the many good things in his remarks.

ASYLUM REPORTS.

The Western Counties Idiot Asylum, Starcross, Exeter (Report for the year ending May 26th, 1900).—The board of management in their report state that the progress of the institution continues to be satisfactory and encouraging. The number of patients in residence on Dec. 31st, 1899, was 250 and comprised 165 males and 85 females. During the year 31 children were admitted, 28 were discharged, and three died. The ages of the children admitted ranged from six to 16 years, the average being 10 years. The majority are regarded as being of a decidedly hopeful character and likely to be greatly benefited by the system of treatment and training adopted at the institution. The degree of improvement effected in patients about to be discharged varied from a slight improvement in habits and general intelligence to a fair degree of industrial efficiency, the former improvement, although apparently of slight importance, being much appreciated by the friends of the children. The manual and industrial occupations taught are as follows. The girls learn dressmaking and needlework, both plain and fancy, straw-hat making, and laundry and ordinary domestic work; while the boys are instructed in shoemaking, tailoring, basket-making, carpentering and woodwork, and the manufacture of sash-cord. Musical and military drill is regularly taught and practised. Mr. E. R. S. Lipscomb, the medical officer, states in his report that the health of the patients throughout the year has been good. There have been no diseases of the zymotic type. One case of broncho-pneumonia recovered, one of pleurisy became worse and tuberculosis was suspected as being present. Two girls developed symptoms of acute mania and had to be removed to another asylum; 35 boys and 15 girls were attacked with influenza of a mild type and all recovered. Two girls died from phthisis and one from membranous croup. The finances of the institution are in a healthy condition, there being a balance of £106 in the hands of the treasurer at the end of the year. Additional ground is being acquired and improvements are in progress as regards the arrangements for the prevention and extinction of fire.

London County Asylum, Bexley Heath (Report for the year ending March 31st, 1900).—At the beginning of the year 1899 262 male patients were housed in the female epileptic and chronic wards and by the end of February the available accommodation for male patients was utilised to the fullest extent, and 300 male patients were under treatment. Early in April, 1899, the remainder of the female wards were ready for occupation. The male patients were all transferred to new wards on April 12th, which allowed for the reception of female patients a week later into the wards which they vacated. The average number of patients resident during the year covered by the report was 704 and comprised 411 males and 293 females. During the year 1165 cases were admitted and of these 499 were males and 666 were females. Dr. T. E. K. Stansfield, the medical superintendent, states in his report that the admissions consisted mainly of patients transferred from provincial asylums and from licensed houses in the metropolis where they had been till then boarded by the London Asylums Committee. The admission and distribution of the patients formed a laborious task, and it is gratifying to be able to state that no casualty or untoward event occurred. "It would be a great boon," says Dr. Stansfield, "if when opening a new asylum one could have all new cases—i.e., recent cases; the introduction of new methods and the attempt to start from the highest rung of the ladders one has previously built is seriously hampered by the introduction of chronically institutioned patients who have been weeded out from other asylums, usually on account of their chronicity and worrying and troublesome habits." Referring only to the "recent" cases of insanity admitted during the year it appeared that intemperance in drink was the cause in 40·25 of the males and 14·2 per cent. of the females, while syphilis was considered to be the predisposing or exciting cause in 22·8 per cent. of the males and 6·6 per cent. of the females. "How easy it was for the most careful clinician to overlook syphilis is well exemplified by a case ..... which had been the subject of several conferences. ..... There was a total absence of traces externally on the body, ... the history of the case was antagonistic to it, and yet the autopsy revealed a gumma situated in the pre-frontal region which was associated with destruction of brain tissue and erosion of the skull, and a scar was found on the os uteri." The clinical features of this case were progressive dementia, the sudden onset of epileptiform convulsions, and the development of status epilepticus, followed by death. 39 males and 27 females were admitted suffering from general paralysis; of the males 31 had evidence of previous syphilis, one was doubtful, and in seven no trace could be made out. Of the 27 females 18 had undoubted syphilis, two were doubtful, and seven had no trace. In one of the females who died the necropsy revealed syphilis which had not been noted clinically. Congenital mental defect was ascertained in 18 per cent. of the male and 15·9 per cent. of the female admissions. During the year 95 patients were discharged as recovered—viz., 31 males and 64 females. One patient escaped. The total number of deaths was 78, being 11 per cent. on the average number resident. In 77 cases post-mortem examinations were made. There was no inquest during the year. A female patient was admitted under restraint wearing a long-sleeved jacket and showing many bruises and festering cuts, evidently the result of destructiveness. Her heart was in a very feeble state, and she succumbed 14 hours after admission. An outbreak of influenza occurred at the end of the year, attacking both patients and staff and handicapping the work of the institution. Five female patients admitted while pregnant were safely confined, one of twins a few hours after admission. The asylum has been lighted by electric light since April, 1899, and with most satisfactory results. Telephones, call-bells, fire-alarms, and tell-tale clocks have been fixed. The calling up of the reserve forces during the war caused a serious drain on the male staff and for a time the working of the male side was conducted with difficulty. The asylum sub-committee state in their report that owing to the limited pasturage available no cows will be kept. The sinking of a well has been completed and during the first seven months about 7,000,000 gallons of water were obtained at a cost of 2·1*d.* per 1000 gallons as against 10*d.* charged by the Kent Waterworks Company. The expenses for repairs and alterations were £2348.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6444 births and 4419 deaths were registered during the week ending March 9th. The annual rate of mortality in these towns, which had been 19·5, 21·2, and 21·5 per 1000 in the three preceding weeks, declined again to 19·5 last week. In London the death-rate was 19·3 per 1000, while it averaged 19·7 in the 32 large provincial towns. The lowest death-rates in these towns were 8·9 in Croydon, 11·6 in West Ham, 13·3 in Wolverhampton, and 13·5 in Blackburn; the highest rates were 23·6 in Manchester, 26·3 in Liverpool, 29·7 in Sunderland, and 34·2 in Plymouth. The 4419 deaths in these towns included 376 which were referred to the principal zymotic diseases, against 347, 387, and 395 in the three preceding weeks; of these 118 resulted from measles, 91 from whooping-cough, 74 from diphtheria, 39 from diarrhœal diseases, 32 from scarlet fever, and 22 from "fever" (principally enteric). No death from any of these diseases occurred last week in Brighton, Norwich, Derby, Birkenhead, or Huddersfield; the highest zymotic death-rates were recorded in Liverpool, Salford, Hull, Sunderland, and Gateshead. The greatest mortality from measles occurred in Liverpool, Leeds, Hull, Sunderland, and Gateshead; from scarlet fever in Burnley; from whooping-cough in Bristol, Wolverhampton, Hull, and Sunderland; and from diarrhœal diseases in Plymouth. The mortality from "fever" showed no marked excess in any of the 33 towns. The 74 deaths from diphtheria included 25 in London, eight in Sheffield, seven in Liverpool, six in Leeds, and five in Leicester. No fatal case of small-pox was registered last week either in London or in any of the 32 large provincial towns, and only one small-pox patient remained under treatment in the Metropolitan Asylums hospitals on Saturday, March 9th. The number of scarlet fever patients in

these hospitals and in the London Fever Hospital at the end of the week was 1746, against numbers decreasing from 2535 to 1823 on the ten preceding Saturdays; 140 new cases were admitted during the week, against 142, 162, and 185 in the three preceding weeks. Influenza was certified as the primary cause of 39 deaths in London last week, as compared with 16, 32, and 35 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 420, 493, and 501 in the three preceding weeks, declined again last week to 463, and were 97 below the corrected average. The causes of 51, or 1·2 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Salford, Newcastle, and in 12 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Sheffield, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·6, 23·7, and 24 5 per 1000 in the three preceding weeks, declined again to 23·4 during the week ending March 9th, but showed an excess of 3·9 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 15·1 in Perth and 18 4 in Aberdeen to 25·3 in Glasgow and 25·5 in Paisley. The 733 deaths in these towns included 51 which were referred to whooping-cough, 20 to small-pox, 15 to measles, 15 to diarrhœa, six to "fever," four to scarlet fever, and two to diphtheria. In all, 113 deaths resulted from these principal zymotic diseases, against 99 and 122 in the two preceding weeks. These 113 deaths were equal to an annual rate of 3·6 per 1000, which was 1·9 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 33, 36, and 67 in the three preceding weeks, declined again last week to 51, of which 30 occurred in Glasgow, 10 in Edinburgh, six in Dundee, and three in Paisley. The deaths from small-pox, which had been 20, 15, and 12 in the three preceding weeks, rose again to 20 last week, and were all registered in Glasgow. The fatal cases of measles, which had been 25, 19, and 13 in the three preceding weeks, rose again last week to 15, of which nine occurred in Edinburgh, three in Leith, and two in Aberdeen. The deaths from diarrhœa, which had been eight, 16, and 23 in the three preceding weeks, declined again to 15 last week, and included six in Dundee and five in Glasgow. The fatal cases of "fever," which had been six and one in the two preceding weeks, rose again last week to six, of which three were recorded in Edinburgh and two in Paisley. The four deaths from scarlet fever corresponded with the number in the preceding week, and all occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 153, 177, and 184 in the three preceding weeks, declined again last week to 161, and were 98 below the number in the corresponding period of last year. The causes of 27, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 33·7 and 46·6 per 1000 in the two preceding weeks, declined again to 39·6 during the week ending March 9th. During the past four weeks the death-rate in the city has averaged 38·6 per 1000, the rates during the same period being 20·1 in London and 22 0 in Edinburgh. The 263 deaths belonging to Dublin registered during the week under notice were 46 below the number in the preceding week and included 12 which were referred to the principal zymotic diseases, against 10, 11, and 12 in the three preceding weeks; of these, 10 resulted from whooping-cough, one from "fever," and one from diarrhœa. These 12 deaths were equal to an annual rate of 1·8 per 1000, the zymotic death-rate during the same period being 1·4 in London and 4·0 in Edinburgh. The deaths from whooping-cough, which had been three, three, and five in the three preceding weeks, further increased last week to 10. The 263 deaths in Dublin last week included 33 of children under one year of age, and 101 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. Nine inquest cases and five deaths from violence were registered; and 91, or more than a third, of the deaths occurred in public institutions. The causes of 11, or more than 4 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING FEBRUARY, 1901.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the 29 cities and boroughs in the county of London. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·7 per 1000 of the population, estimated at 4,651,113 persons in the middle of this year. In the three preceding months the rates had been 10·0, 8·0, and 6·2 per 1000 respectively. The rates were considerably below the average in Paddington, Kensington, City of Westminster, City of London, Shoreditch, Lambeth, and Battersea; while they showed the largest excess in Fulham, Poplar, Bermondsey, Deptford, Greenwich, and Lewisham. Two cases of small-pox were notified last month, of which one occurred in St. Pancras and one in Wandsworth; one case was admitted into the Metropolitan Asylums hospitals during the month, and remained under treatment on Saturday, March 2nd. Scarlet fever showed a considerably diminished prevalence last month as compared with the five preceding months; among the various metropolitan boroughs this disease was proportionately most prevalent in Fulham, Chelsea, Holborn, Deptford, Greenwich, and Lewisham The Metropolitan Asylums hospitals contained 1791 scarlet fever patients at the end of February, against 2659, 2460, and 1979 at the end of the three preceding months; the weekly admissions averaged 156, against 259, 214, and 164 in the three preceding months. The prevalence of diphtheria showed no appreciable variation from that recorded in the preceding month; the greatest proportional prevalence of this disease occurred in Fulham, Hampstead, Stoke Newington, Poplar, Bermondsey, and Deptford. There were 1111 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1524, 1343, and 1113 at the end of the three preceding months; the weekly admissions averaged 136, against 185, 127, and 129 in the three preceding months. The prevalence of enteric fever last month showed a further decline from that recorded in the three preceding months; among the various metropolitan boroughs this disease was proportionally most prevalent in Islington, Bermondsey, Stepney, Greenwich Woolwich, and in the City of London. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 436, 403, and 299 at the end of the three preceding months, had further fallen to 224 at the end of February; the weekly admissions averaged 25, against 61, 51, and 32 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Stoke Newington, Bethnal Green, Stepney, Poplar, and Greenwich boroughs. The 24 cases of puerperal fever included five in Islington, two in Hackney, two in Stepney, two in Lambeth, and two in Battersea.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the various boroughs in which the patients had previously resided. During the four weeks ending March 2nd, the deaths of 6905 persons belonging to London were registered, equal to an annual rate of 19·4 per 1000, against 16·8, 16·2, and 17·5 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 12·2 in Hampstead, 13·0 in Wandsworth, 15·2 in Lewisham, 15 6 in Hackney, 16·1 in Stoke Newington, and 16·4 in Fulham; the highest rates were 23·4 in Bethnal Green, 23·8 in Poplar, 25·8 in Holborn, 26·4 in Southwark, 26 6 in Shoreditch, and 27·4 in the City of London. During the four weeks of February 547 deaths were referred to the principal zymotic diseases; of these, 126 resulted from measles, 18 from scarlet fever, 95 from diphtheria, 216 from whooping-cough, one from typhus, 33 from enteric fever, one from simple continued fever, and 57 from diarrhœa. The lowest death-rates last month from these diseases occurred in St. Marylebone, Islington, Stoke Newington, Holborn, Finsbury, Shoreditch, and Wandsworth; and the highest rates in Hammersmith, Southwark, Bermondsey,

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING FEBRUARY, 1901.

* Including 14 cases of membranous croup.

† Including deaths from membranous croup.

Camberwell, Deptford, and Greenwich. The 126 deaths from measles showed a decline of 62 from the corrected average number; this disease was proportionally most fatal in Hackney, Bethnal Green, Southwark, Camberwell, Deptford, Greenwich, and Lewisham. The 18 fatal cases of scarlet fever were less than one-third of the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Hammersmith, St. Marylebone, Southwark, Deptford, Lewisham, and Woolwich. The 95 deaths from diphtheria showed a decline of 78 from the corrected average; this disease was proportionally most fatal in Hammersmith, Hampstead, Bethnal Green, Poplar, Deptford, and Woolwich. The 216 deaths from whooping-cough were slightly below the average in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease showed the greatest proportional mortality in Kensington, Hammersmith, Chelsea, Shoreditch, Bermondsey, and Battersea. The 35 deaths from "fever" almost corresponded with the corrected average number; the highest "fever" death-rates occurred in Paddington, St. Marylebone, Hampstead, Holborn, Stepney, and Woolwich. The 57 fatal cases of diarrhœa were slightly in excess of the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, Hackney, Stepney, Poplar, Deptford, and Lewisham. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during February was nearly 27 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 126 per 1000. The lowest rates of infant mortality were recorded in Hampstead, Stoke Newington, Holborn, City of London, Wandsworth, and Greenwich; and the highest rates in Fulham, St. Pancras Shoreditch, Poplar, Southwark, and Deptford boroughs

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are announced:—Staff Surgeons: A. G. Wildey to the *Revenge;* J. H. Acheson to the *Pallas;* O. W. Andrews to the *Colossus;* R. W. Anderson to the *Medusa;* W. H. Norman to the *Caledonia;* and E. R. D. Fasken to the *President*. Surgeons: J. S. Dudding to the *Boscawen*, for the *Seaflower;* W. Bastian to the *St. Vincent*, for the *Martin;* R. W. B. Hall to the *Impregnable*, for the *Nautilus;* G. Ross to the *Boscawen*, for the *Dolphin;* H. C. Adams to the *Impregnable*, for the *Pilot;* and R. R. Horley to the *Lion*, for the *Liberty*.

Staff Surgeons J. Acheson, H. S. R. Sparrow, A. Kidd, and J. Beattie have been promoted to the rank of Fleet Surgeons.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel Henry Walter Kiallmark, having attained the prescribed limit of age, is removed from the Army Medical Reserve of Officers.

VOLUNTEER CORPS.

Artillery: 1st City of London (Eastern Division, Royal Garrison Artillery): Surgeon-Captain H. Stedman, from the 1st Volunteer Battalion the Northamptonshire Regiment, to be Surgeon-Captain. 1st City of London (Eastern Division, Royal Garrison Artillery): Surgeon-Major F. G. Bennett, whose retirement appeared in the *London Gazette* of Oct. 18th, 1889, is permitted to retain his rank and to wear the uniform of the corps on retirement. *Rifle:* 2nd Volunteer Battalion the East Surrey Regiment: Surgeon-Lieutenant J. E. Bates to be Surgeon-Captain. 1st Herefordshire: Surgeon-Lieutenant John Jamieson Wallace resigns his commission and is appointed Second Lieutenant. 2nd Volunteer Battalion the Essex Regiment: Surgeon-Captain J. W. Cook resigns his commission. 3rd Lanarkshire: Brigade-Surgeon-Lieutenant-Colonel J. Dunlop retires, with permission to retain his rank and to wear the uniform of the corps on retirement. 1st Wiltshire: Surgeon-Lieutenant H. L. E. Wilks to be Surgeon-Captain 1st Cadet Battalion the Manchester Regiment: Acting Surgeon Israel James Edward Renshaw to be Surgeon-Captain. 2nd Volunteer Battalion the Prince of Wales's (North Staffordshire Regiment): Frederick Nesfield Cookson to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies: Surgeon-Captain J. B. M. Anderson resigns his commission.

SOUTH AFRICAN NOTES.

Lieutenant Taylor, R.A.M.C., has slightly improved (Howick, March 9th). Civil Surgeon Bruce is progressing favourably and is out of danger (Newcastle, March 8th). Civil Surgeon O'Reilly is reported out of danger at Kimberley.

Lieutenant-Colonel J. D. Day, R.A.M.C., Lieutenant J. J. W. Prescott, R.A.M.C., and Civil Surgeon H. S. H. Callum have been discharged from hospital to duty.

DEATHS IN THE SERVICES.

Surgeon-Major Daniel Paterson Barry, M.D. St. And., A.M.D. (retired), at Tunbridge Wells, on March 3rd, aged 75 years. He entered the army in 1846, became Surgeon in 1854, Surgeon-Major in 1866, and retired in 1867. He served with the 1st Battalion. 60th Rifles in the Punjab campaign of 1848-49, and was present at the siege of Mooltan, and at the battle of Goojerat (medal with two clasps). In the Crimea he was at the battle of Tchernaya and the siege and fall of Sebastopol (medal with clasp and Turkish medal). With the 97th Regiment he served during the Indian Mutiny campaign of 1857–58, and was present at the siege and capture of Lucknow (medal with clasp).

Surgeon-General Albert Augustus Gore, C.B., Army Medical Staff (retired) on March 11th, at his residence, Dodington-lodge, Whitchurch, Shropshire, aged 61 years. He joined the Army Medical Staff as assistant surgeon in 1860, and served with the 16th Lancers. In West Africa he was at the bombardment and destruction of the Timmance town of Massougba on the Sierra Leone river on Dec. 10th, the attack on Madoukia on Dec. 27th, and the storm and capture of the stockaded fetish town of Rohea on Dec. 28th, 1861 (mentioned in general orders for his services and for conspicuous bravery and specially recommended for promotion). In the Ashanti war of 1873 he acted as sanitary officer and was severely wounded in the action of Nov. 3rd near Dunquah, and was also wounded at Quarman on Nov. 17th (medal). It fell to the lot of the late Surgeon-General Gore, whilst Surgeon-General of Her Majesty's forces in India, to organise and make all the medical arrangements for the Chitral expedition and for the very large force from the North-Western frontier under the late Sir William Lockhart—the latter being a task which must have entailed a vast amount of work and responsibility. We were enabled to furnish our readers, it will be remembered, with full information at that time in regard to those arrangements and as to the sick and wounded, the hospitals, and many other interesting details. The late officer was a very hard-working, conscientious man with an unusual knowledge of military detail.

Deputy Surgeon-General Thomas Murray, I.M.S. (retired), at Upper Norwood on Feb. 15th. He joined the Bombay Army on March 7th, 1846, and retired July 31st, 1876, and served in the 10th Regiment, Bombay Light Infantry, from 1851 to 1876, and was present with it at the assault and capture of Kotah in March, 1858, by the force under the command of Major-General Roberts; during the operations of Brigadier Smith's Brigade in Central India, and present at the battle of Kotah-ke-Serai, June 17th, 1858; at the capture of Gwalior on June 18th, by the force under Sir Hugh Rose; at the siege and capture of Powree in August, 1858, by the field force under Brigadier-General Robert Napier, and acted as senior medical officer with the flying column under Lieutenant-Colonel Robertson in the subsequent pursuit and defeat of the rebels at the action of Beejapoor; with Brigadier Smith's brigade in Central India during the pursuit of the Gwalior rebels under Tantia Topee and Maun Sing; present at the action of Koondrye on Nov. 14th, 1858; also at capture of Magdala in 1868 by the force under the command of General Sir Robert Napier.

THE WAR IN SOUTH AFRICA.

The number of cases of plague at Cape Town is slowly but surely increasing, we are sorry to say. Since its first outbreak on Feb. 7th last there have been altogether about 100 cases with, it is stated, some 30 deaths. Parts of Cape Town are very much overcrowded and some

of the worst districts are very bad indeed, although a good deal has been done to cleanse and improve them. Considering that Cape Town is the nearest and most convenient port, the outbreak of plague there is, even apart from other serious considerations, likely to prove a source of much embarrassment under present circumstances. As regards the war there are persistent rumours, for which there seems this time to be official grounds, that General Botha is endeavouring to arrange terms for the surrender of his force, and there are signs in other directions that the foundations of the Boers' resistance are being roughly shaken. The time has come, as we have already said, when the Boers must fight to live instead of living to fight as they have hitherto done. The sweeping method of procedure now being systematically carried on by the British forces clears the country of its supplies of horses, vehicles, and supplies, while the huge captures of Boer convoys with cattle, horses, food, and munitions of war, must have told very seriously indeed on their resources. The collapse of the scheme of invasion of Cape Colony and the persistent pursuit of De Wet and his forces cannot fail to have a disheartening effect on the Boers. There does not seem much room for doubting that altogether the news from South Africa is more favourable.

The progress of active military operations has been greatly interfered with by the bad weather and heavy rains which have been prevalent of late. The casualty returns still give sad lists of sickness and losses (mostly from enteric fever) in addition to those shorter lists attributable to wounds and injuries.

MENTIONED IN DESPATCHES.

The following paragraph appears in a despatch which has been received by the Secretary of State for the Colonies from Colonel Sir J. Willcocks, dated Cape Coast Castle, Dec. 25th, 1900:—"The various departments of the field force have been well administered. The medical, under Dr McDowell, principal medical officer, in my opinion has been as near perfection as was possible in such a country. He was given an absolutely free hand and nothing that was asked for or wanted was ever refused. The supplies from England have been sent out so promptly and in such a generous spirit that it was the universal opinion that no force in the field could have been better treated."

The following officers are mentioned as having done very good work:—Dr. W. Murray, Gold Coast Medical Service; and Dr. D. Gray, British Central Africa Medical Service.

The following are excerpts from despatches which have been received from Vice-Admiral Sir Robert Harris, K.C.M.G., Commander-in-Chief on the Cape of Good Hope Station, reporting the proceedings of the Naval Brigades in South Africa:—

"Surgeon James G. Fowler has been most assiduous in his attendance and duties towards the sick."

"Staff Surgeon Lilly and Surgeon Lomas were indefatigable, and on the spot instantly to attend our wounded under an exceedingly hot shell fire."

"Fleet Surgeon James Porter of H.M.S. *Doris*" (also specially mentioned for excellence of medical arrangements), "for the efficiency of the arrangements for attending the wounded with the limited staff at his command."

Major William Grant Macpherson, R.A.M.C., and Lieutenant-Colonel George Sterling Ryerson, M.D., are among the recently made Knights of Grace of the Order of the Hospital of St. John of Jerusalem in England.

A SANATORIUM FOR WALTHAMSTOW.—A new sanatorium, erected by the Walthamstow Urban District Council at a cost of £30,000, was formally opened at Chingford on Saturday last by the chairman of the Sanitary Committee of the Council. The buildings, which are beautifully situated on the borders of Epping Forest, occupy a site of about five acres and consist of an administrative block and three pavilions. Each of the latter provides accommodation for 14 beds, together with nurses' rooms, bathrooms, lavatories, and discharging rooms. There is also a smaller pavilion for doubtful cases. Mr. J. J. Clarke, medical officer of health to the Council, made a short statement as to the future administration and work of the sanatorium and said that the staff would consist of a resident medical superintendent, matron, assistant matron, three charge nurses, and four probationers.

"Audi alteram partem."

THE DUTIES OF HOUSE SURGEONS AT THE EAST SUFFOLK AND IPSWICH HOSPITAL.

To the Editors of THE LANCET.

SIRS,—My colleague, Mr. C. C. Worts, and I yesterday received six weeks' notice of the termination of our engagements as house surgeons here under circumstances which seem to us gravely to affect the honour of the profession. It concerns the relations of house surgeons to the press. It has been for some years here the custom for the inclosed form to be filled in and handed in the evening to reporters.

[INCLOSURE.]

EAST SUFFOLK AND IPSWICH HOSPITAL.

ACCIDENT ADMITTED.

Signed

.....

House Surgeon.

When we came into office some weeks ago we refused to follow out that custom on the ground that it lay with the patient only or his nearest relatives to decide what information, if any, was to become public property. A house surgeon is not in a position to know whether any information would or would not be prejudicial to a patient. Even the knowledge that a man has had a broken leg might hinder him again getting employment in certain positions. It is our duty to give the patient's family information about him, and to them we referred the reporters. We take our stand on the principle that it is unprofessional conduct to give the press information, as a general rule at all events, and we also regard it as highly inexpedient in these days of Employers' Liability Acts and insurance to give such information. Some time ago Mr. Elkington, the editor of the *East Anglian Daily Times*, called on my colleague and demanded that we see his reporters, saying "A daily paper must be run." Mr. Worts said he would not stand in the way of his getting any information as he best could legitimately, but that we would give none ourselves. The editor is a member of the weekly board of this hospital. On Feb. 20th we were called up to the weekly board and the following resolution was read to us:—

That the house surgeons be instructed to give such information to the press with reference to accident cases as may be reasonable and sufficient in accordance with precedent.

Moved by Mr. Fosdeck, seconded by Dr. Casley. We refused to obey the resolution or to resign and were then told that a letter of dismissal would be sent to us.

Now, by their own rules (which I inclose), Nos. 22 and 77, the weekly board, not being specially summoned, were exceeding their powers both in making a new rule and in dismissing us. However, next week, on Feb. 27th, a specially summoned meeting of the board of management was held to discuss our dismissal, and if deemed advisable to dismiss us. We were not summoned. The meeting was adjourned for a week. Meanwhile, on March 4th, the medical staff met together, Dr. Casley alone being absent, and they unanimously resolved that our attitude was ethically correct. They also suggested that we be asked to give information to the press after asking the patient's permission. On March 6th the resolutions of the staff were read to the board, but were ignored as irrelevant. The resolution dismissing us was passed by a majority of ten; only four voted against

it—viz., Dr. W. A. Elliston (President of the British Medical Association), Dr. T. Warner, Dr. W. W. Sinclair, and Mr. Felix Cobbold (president of the hospital). Dr. Casley voted for the resolution. Mr. Branford Edwards, Dr. R. W. Brogden, Dr. H. H. Brown, and Dr. F. Ward were present but did not vote. Later we were served by the secretary with six weeks' notice, no reason being given for our dismissal.

Now, even if our view of the ethics of the question be regarded as unduly strict—though I do not for one instant assent to that—still it would have been easy for the board to have arranged for information to have been given to the press by the secretary or some other official. To dismiss us is as unnecessary, even from their point of view, as it is unjust from any point of view. I am confident that I am fully justified in placing the matter before the profession and in asking for the support of THE LANCET.

I am, Sirs, yours faithfully,

RICHARD KAY, M.B. Lond.,
Senior House Surgeon.

March 7th, 1901.

*** Dr. Kay and Mr. Worts have acted throughout in accord with medical ethics. We trust that the board will reconsider their action and will suppress all personal feelings in dealing with the matter. The question is not only what is fair to the house surgeons or due to the press. The interests of the patients must be put first. We deal with the matter in a leading article.—ED. L.

"THE STATISTICS OF GASTRIC ULCER, WITH SPECIAL REFERENCE TO GASTRIC HÆMORRHAGE, ITS FREQUENCY AND FATALITY."

To the Editors of THE LANCET.

SIRS,—In my address on Gastrorrhagia before the Medico-Chirurgical Society of Edinburgh, in attempting to elucidate the difficult question of treatment I thought it desirable to make use of the statistics collected by well-known authorities: (1) on the frequency of gastric ulcer; (2) on its fatality; (3) on the frequency of gastrorrhagia; and (4) on its fatality. From these statistics I hoped to show the importance of the subject and to deduce conclusions that would help to make the subsequent discussion useful.

Dr. Byrom Bramwell, in a clinical lecture published in THE LANCET of March 9th, p. 687, states that these conclusions are not in accordance with his own experience, and he objects to the method of taking the mean of the figures given by the various authorities whose statistics are made use of, and also to some of the statistics which were published about 40 years ago and which, I would mention, have become classical and are accepted by all authorities on the subject to-day. I fully agree with Dr. Bramwell as to the difficulty of basing arguments on a statistical foundation, for objections can generally be raised against all statistics; but it seemed to me that the questions I was considering were such as could only be settled on statistical evidence, and by using only those statistics approved of by everyone who has written on the subject, and in taking the mean of the figures, I thought I was adopting a basis for my arguments almost above criticism.

It will be more convenient to take each set of statistics separately.

1. *As to the frequency of gastric ulcer.*—The usual estimate accepted by all authorities is that 5 per cent. of the whole population suffer at some period of their lives from simple ulcer of the stomach. In 32,052 necropsies collated and analysed by Welch, ulcers or scars caused by them were found in 4·7 per cent., but Dr. Bramwell raises objections to the post-mortem method of estimation—(1) because all open ulcers are not found; (2) because cicatrices of former ulcers are often missed; (3) because superficial ulcers probably do not leave a cicatrix when they have healed; and (4) because some of the scars found may be due to other causes than ulcer, such as syphilis, tubercle, &c.; but as Dr. Bramwell does not press the last objection we will omit it from the argument, for it is well known that other causes (than ulceration) of cicatrices in the stomach are very rare indeed.

I heartily concur in these three objections, but surely they only make the position all the stronger, and one naturally asks the question—If 5 per cent. of ulcers or cicatrices are positively found in all necropsies, how many more must escape observation, and how much does 5 per cent. underestimate the frequency of gastric ulcer?

Dr. Bramwell next objects to the statistics of British hospitals, so far as gastric ulcer is concerned, being compared with certain German hospitals where exact observations have been made and noted in the post mortem rooms for many years. Of course, it does not follow that the same percentage of cases occurs in British hospitals, but it remains to be proved by an equal number of careful observations that this is not the case before Dr. Bramwell's opinion on the subject can have the same weight as that of those great authorities whose estimates have hitherto been accepted by all who have written on the subject. The frequency of gastric ulcer in the community outside hospitals must always be a difficult matter to settle, as its estimation depends so much less on exact post-mortem evidence and so much more on clinical observation, to which Dr. Bramwell justly raises objection; but, if I may judge by my own experience, I have had a far greater number of *private* than of *hospital* patients sent to me for an opinion with regard to the surgical treatment of gastric ulcer. This, however, is no more a proof of the greater prevalence of gastric ulcer in the well-to-do than is Dr. Bramwell's opinion as to gastric ulcer being less frequently found in this class of patient, his opinion, so far as I can gather, being based chiefly on clinical evidence to which he has so much objected. Autopsies or biopsies afford us the only absolute proof of ulcer of the stomach, and without such proof there must always be uncertainty. I can see no need, therefore, to alter the numbers which, for making the importance of the subject more tangible, I applied to the population of a city like Leeds, which, for convenience' sake, I took at 500,000, though Leeds itself has actually only a population of between 400,000 and 500,000.

2. *The total mortality from gastric ulcer.*—I was very much astonished to find Dr. Bramwell making use of the Registrar-General's returns for the purpose of disproving the statistics I quoted, and I should like to ask if Dr. Bramwell really seriously argues that the Registrar-General's return of deaths from gastric ulcer can be pitted against the statistics of such able physicians and keen observers as Brinton, Welch, Dreschfeld, Habershon, Müller, Lebert, Tricomi, and others? How about the classification of subphrenic abscess, acute peritonitis, localised abdominal abscess, intervisceral fistulæ, gastric dilatation, general atrophy, marasmus, anæmia, and phthisis (of stomach origin) and ulcus carcinomatosus, to say nothing of many other diseases ending in death which should have recorded as their first cause ulcer of stomach? I see that Dr. Spottiswoode Cameron has even pointed out to Dr. Bramwell one or two of these sources of fallacy. I do not think, therefore, that if, as Dr. Bramwell says, 17 deaths were reported as due directly to gastric ulcer and six to hæmatemesis in Leeds last year, it will be far from the mark to say that three or four times as many would be likely to die directly or indirectly from the complications due to the same disease.

The difference in the views of various authorities who give the rate of mortality in all cases of ulcer as varying from 10 to 50 per cent. is really a question of the inclusion or not of the cases dying indirectly from ulcer, for if they are included—and to my mind they should be—the mortality is much greater than the profession at large really grasps and than Dr. Bramwell acknowledges. The subject rather reminds me of arguments that were used a few years ago when it was not unusual to hear it said that deaths never occurred from appendicitis, but I never hear that argument used now; and, with regard to ulcer, it only requires time to prove that the figures I have employed will not be far from the truth.

3 & 4. *On the frequency of gastrorrhagia and its fatality.*—Dr. Bramwell should really be careful before he accuses anyone of making a serious error, especially when he pits his individual experience and opinion against the experience of the authorities quoted from and whose statistics I will again repeat: "Müller, 11 per cent.; Welch, 3 to 5 per cent.; Brinton, 5 per cent.; Debove, 5 per cent.; Steiner, 6·36 per per cent.; Lebert, 3 per cent.; Dreschfeld, 3½ per cent.; and Rodman, 8 per cent."; these numbers representing percentages of fatal hæmatemesis in bleeding ulcers. As different authors estimate the percentage of hæmatemesis in all cases of gastric ulcer somewhat differently it is difficult to classify them on the same lines. I have therefore adopted purposely a low estimate in saying that 50 per cent. of all cases of ulcer of the stomach suffer from gastrorrhagia and

have made a low estimate of the mortality in saying that 7 per cent. of deaths in cases of gastrorrhagia from ulcer will not be far from the truth.

In order to make my position clear I said in my address: "If this is worked out in the 500,000 population of a city *like* Leeds [Leeds, as I said before, does not reach 500,000; this is a mere quibble on the part of my friend] it means that of the 25,000 persons who have or have had ulcer, 12,500 suffer from hæmatemesis and of these 7 per cent., or 875, die." If this be further worked out, even on Dr. Bramwell's lines of excluding children under the age of five years, it will mean that 22 persons die annually from gastrorrhagia in a city of 500,000 inhabitants, and in spite of Dr. Bramwell's criticisms and quotations from the Registrar-General's reports, I believe that this is, if anything, an under-estimate of this serious accident. To show that my views are supported by a physician whom I feel sure that Dr. Bramwell will acknowledge is an authority on the subject, I will quote from Dr. Fenwick's work on "Ulcer of the Stomach" published in 1900, p. 50:—"Hæmorrhage from the stomach is a frequent cause of death in gastric ulcer. Out of 112 fatal cases recorded at the London Hospital, 18, or 16 per cent., died from hæmatemesis, while in another series of 298 necropsies on gastric ulcer we find that fatal hæmorrhage occurred in 56 cases, or in 18·8 per cent."

Dr. Bramwell, in speaking after I had given my address, remarked that "he had never, so far as he remembered at present, seen a fatal case of hæmorrhage from a simple gastric ulcer," yet when he wrote his lecture a few days later he was able to call to mind two fatal cases. Perhaps if Dr. Bramwell could ascertain the after-history of some of the other cases he has seen in consultation he might possibly find an even greater mortality. Surely the difference in Edinburgh and in London cannot be so great as is shown in the passage I have quoted from Dr. Fenwick and the statements made in Dr. Bramwell's lecture.

I am sorry to trouble you with such a long letter, but out of justice to myself as well as from the interest I take in the subject, I have felt it necessary to try to show that the dangers of gastric ulcer and of its complication, gastrorrhagia, are both as frequent and as serious as I stated in my address, and the only apology I have to make is to those eminent authorities whose figures I have in some cases almost halved in order to state my views with moderation.

I am, Sirs, yours faithfully,

March 12th, 1901. A. W. MAYO ROBSON.

To the Editors of THE LANCET.

SIRS,—I find that there are two mistakes in the figures in my paper on the Statistics of Gastric Ulcer in THE LANCET of March 9th, p. 687, which perhaps you might kindly insert a note correcting.

On page 690. second column, 14 lines from the bottom, instead of 49·87, read 76·92; and on page 691, second column, 14 lines from the top, instead of 413,287 read 431,287. I am, Sirs, yours faithfully,

March 12th, 1901. BYROM BRAMWELL.

"THE CURATIVE TREATMENT OF MICROBIC DISEASE."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of August 4th, 1900, p. 350, you published a letter of mine on a method of treating microbic diseases. I am now in a position to state that since that date some 30 or 40 animals (sheep) suffering from a peculiar febrile disease known as "heart-water," from the effusion of liquid into the pericardial sac, have been cured by the method I advocated then and also as early as 1890.[1] There have been only three deaths, which is very gratifying, as the usual mortality varies from 50 to 60 per cent., or even more, from this disease. My curative method consists in, first, thoroughly bleeding the sick animal (about 15 ounces) and then injecting subcutaneously about eight cubic centimetres of defibrinated blood obtained from a recovered animal.

Now, there are at least three diseases which occur in the human subject—viz., pneumonia, bubonic plague, and typhus fever—in which I believe this method of bleeding, does good. It must be followed by the injection of the appropriate serum for the two first-mentioned diseases—viz., Yersin's serum for plague and Klemperer's serum for pneumonia, and recovered blood from a healthy subject (after typhus) for the last-mentioned disease. A serum obtained from the horse would be preferable, but as yet it is not obtainable. The blood of a fever patient, and in case of his death splenic emulsion (in salt solution), may be tried for inoculating a horse in order to obtain an antitoxic or antimicrobic serum for this disease (typhus fever) which is so fatal in certain parts of Ireland, Scotland, and the North of England. The amount of bleeding to be at all serviceable should not be less than 10 ounces (15 ounces would be about the usual quantity for an adult). The object of this free bleeding is, of course, to remove as much of the toxin (and germs?) as possible. A medical friend of mine who has had great experience of typhus fever at home tells me that he has noticed that in almost all cases of bleeding (e.g., epistaxis) the crisis has been hastened and the patients have made a good recovery.

I am, Sirs, yours faithfully,

GEO. CARRINGTON PURVIS, M.D. Edin.

Grahamstown, Cape Colony, Feb. 9th, 1901.

[1] THE LANCET, Dec. 20th, 1890, p. 1354.

OTORRHŒA AND SCHOOL BOARD CHILDREN.

To the Editors of THE LANCET.

SIRS,—The number of cases of otorrhœa and its consequences that come under our care in the out-patient department is very great and, according to my experience, now extending over 25 years, the numbers do not decrease. It seems a pity that something cannot be done to check this disease. Recognising that the School Board now gets hold of these children at an early age I wrote to the clerk of the Board suggesting that some scheme might be arranged by which the ears of the children might be examined when they first enter the schools and then perhaps once a term afterwards. I pointed out the dangers they ran and the offensive condition which many of them were in. The Board, however, refused to consider the subject and their medical officer, to whom I likewise wrote, replied that he could do nothing in the matter. I cannot help thinking that it is most important for the future well-being of these children that some check should be put to the ravages of otorrhœa and I am sure that if you and other medical journals will give your powerful aid an immense amount of good may be done. It seems to me that the School Board is the best authority through which to work, as practically all the children pass through their hands. No other authority could with so little trouble, expense, or "interference with the liberty of the subject" give so much assistance in checking this disease. The eyes of the children are now examined with great benefit. Why, then, should not the ears be done so too? They are certainly equally important.—I am, Sirs, yours faithfully,

W. R. H. STEWART, F.R.C.S. Edin., &c.,
Surgeon to the Ear and Throat Department, Great Northern Central Hospital; Consulting
March 12th, 1901. Surgeon, London Throat Hospital.

AUSTRALIAN WINES.

To the Editors of THE LANCET.

SIRS,—An analytical report was published in THE LANCET of Sept. 29th, 1900, p. 949, upon samples of Australian wines. The report appears to have been based upon the assumption, a postulate I believe very generally accepted, that wine cannot in natural fermentation produce more than about 24 degrees of alcoholic strength, and that any excess of that strength indicates *per se* the addition of spirit. Dealing with the subject in its broad sense, I hope to show that this theory applied to wines grown in Australia is fallacious. My personal knowledge of Australian wines extends over 30 years, during which many millions of gallons have passed under my observation; though my firm do not analyse the wines they grow or purchase they know them to be perfectly pure as nature produces them, although many growths exceed the strength of 24 degrees proof spirit.

So far back as the year 1874, in examination before the Royal Commission of the House of Commons, I was able to produce evidence, supplied by the South Australian Government, proving that three analysts in that colony had obtained from the same grapes, supplied by that Government, strengths up to 35 degrees, and that Sir Samuel Davenport had produced on the "Beaumont Vineyard" a wine showing 20·743 degrees alcohol by weight, equivalent to 44·522 degrees proof spirit. Upon such evidence the Royal Commission recommended that the standard for natural wines should be

raised from 26 to 30 degrees, at which it stands to-day. It has been usual to allow the grapes to remain longer on the vines in Australia than in European vineyards, and thus, becoming thoroughly ripe, they yield less *must* or juice, but more saccharine. So large is Australia, and its climate and soil are so varied, that every grade of wine, from the light Chablis with 21 degrees of proof spirit to Constantia of 44 degrees, can be produced; the aspect and altitude, and in no less a degree the particular kinds of the vine grown, bear a large share in the result. One well-known very free-bearing red grape yields, I believe, in some seasons as much as 800 gallons per acre. The wine from it is thin, poor, hungry stuff; it arrives at its maturity in three years and then often "goes to pieces." It has a strength of about 21 degrees of spirit, and some Australians flatter themselves it is claret, but clarets are obtained from different grapes altogether, and claret vines produce in Australia another style of wine. I have such before me now grown on a vineyard of my own in the warm district of Rutherglen. The grapes were allowed to remain on the vines till thoroughly ripe; the resulting wine has 28 degrees spirit, is somewhat sweet, and of most delicious flavour. That no spirit was added to it is beyond question; there was no still on the vineyard, and the rules of the Excise prohibit the transfer of spirit between vineyards.

In England, as elsewhere, tastes are constantly changing, and this may be affecting the claret trade now, for during the past year the imports from France have fallen off 594,570 gallons. It is evident, therefore, that however elegant the light wines from France may be the public taste at present favours wine with more substance. As Australia is able to produce these robust wines, which the public by the increasing yearly imports prove they are favouring, it is, I think, a pity that an impression should be conveyed to your readers that the generous quality which these Australian wines exhibit is the result of adventitious spirit; this, I fear, was the idea your article conveyed, based, as I have said, on exploded theories.

In France and Germany the grapes are gathered before they are dead ripe; were this not so it would be at the expense of bouquet, besides which the fermentation to complete attenuation might be frustrated, and the dry wine known as claret could not be obtained. In Australia it is natural to produce big wines; the fruit being allowed to come to maturity the aqueous particles become in a measure evaporated, and the result is such stout Burgundy as was thought impossible before Australian wines were known. As instance of the heat in the colonies and its effects on the vines, the leaves are allowed to remain on the branches so as to protect the bunches from the sun, whereas in France and Germany the leaves are thinned, and indeed the vine is sometimes trained on trellises capable of being moved at any angle, so as to obtain all the sun possible, as well as the heat radiated from the ground.

Australian wines should not be compared with those of France and Germany more than with those of Spain, Portugal, or Sicily. For, on the one hand, in the warmer climates more sugar is produced with more spirit and weight of wine; on the other, in the more temperate climates lighter wines, more elegant perhaps but colder, are the result. If, then, the English public continue the taste for light, thin, dry wines, I know no country that can supply them finer than France or Germany. But if the taste, as I am led to believe, is for the more generous product of fully ripe grapes, there is no country in the world can supply the want better than our own possessions.

It has been the endeavour of Australian wine-growers to put on the market that which Australia can best produce—viz., a natural robust wine filling the gap between the light wines of the continent and fortified wines. To quote the remark of a writer in the *Standard*: "Australian wines abound in memories of the sun that begot them and, like the wines of the ancients, will bear mixing with water."

I am, Sirs, yours faithfully,

Feb. 25th, 1901. P. B. BURGOYNE.

*** We refer to this letter in an annotation this week.—ED. L.

THE VALUE OF SALINE ENEMATA.

To the Editors of THE LANCET.

SIRS,—I have read with great interest the very sensible article in THE LANCET of March 9th, p. 720, on the Value of Saline Enemata in Collapse and in Uræmia and Puerperal Eclampsia. Allow me to call your attention to another class of cases in which I have found them very useful. I refer to cases of gastric ulcer in which (not necessarily due to large hæmorrhage) there may be subsequently extreme weakness and debility, sleeplessness, &c., if not actual collapse. This is due, no doubt, largely to abstinence from food by the mouth, rectal feeding being only a poor substitute for natural alimentation. In such cases saline injections at 100° F., in quantity (say half a pint) sufficiently small to be readily retained, have been frequently given to a case of gastric ulcer, now nearly recovered, in which the return of refreshing sleep (after much restlessness, nausea, &c.) at once took place after the first injection. A like result was noticed later and the injections were repeated.

I am, Sirs, yours faithfully.

Chepstow, March, 1901. J. CROPPER, M.B. Cantab.

HYPERTROPHY OF THE LINGUAL TONSIL.

To the Editors of THE LANCET.

SIRS,—In a deservedly favourable notice of Dr. Escat's "Maladies du Pharynx" in THE LANCET of March 9th, p. 711, the reviewer writes that, "like too many observers Dr. Escat looks upon hypertrophy of the lingual tonsil from the point of view that the condition is the disease, whereas it is a local manifestation of a more general disturbance." This is not quite the view held by Dr. Escat as I read him, but if there are "too many observers" of his way of thinking does it not suggest that there are but few who think differently?

I am, Sirs, yours faithfully,

March 12th, 1901. LENNOX BROWNE.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Inoculation for Rinderpest.—Great Increase of Plague.—The Admission of Natives to the Indian Medical Service.—The Water and Milk-supply of Indian Cities.

A REPORT has recently been issued by Dr. A. Lingard showing the results of inoculation against rinderpest during the past year. The process has been carried out at several places with marked success. The method of protection adopted is to inject a small dose of the protective serum on one side of the body and at the same time a small dose of virulent rinderpest blood on the opposite side. Reaction follows in 90 per cent. and this gives practically permanent immunity. In about 10 per cent. no apparent reaction occurs although it is found that the cattle possess some immunity which lasts for a few months. In these latter instances a subsequent re-inoculation with from 1 to 10 cubic centimetres of virulent blood about 10 days later produces the usual reaction and confers the required lasting immunity. It is found that the hill cattle react differently to those of the plains, the former requiring much more frequently the subsequent re-inoculation with virulent blood. The use of the protective serum alone causes no reaction, but yet affords a temporary immunity. This is sufficiently lasting to afford protection during an epidemic and it is therefore particularly applicable for milch cows when it is not desirable to interfere with the milk-supply, and it is also useful in the case of pregnant animals which under the disease itself, whether artificially or naturally acquired, are liable to miscarry. An instance of an outbreak in Madras is given where 339 bullocks were inoculated. The disease was at once checked, and it is almost certain that a heavy loss among the cattle was averted. During the year no less than 464,765 cubic centimetres of protective rinderpest serum were manufactured. A large stock ready for immediate despatch is kept at the laboratory, and in addition a further large stock only requiring a fortnight's time for being tested.

Close upon 6000 deaths from plague took place in India last week. The week before there were 4377 deaths, and in the corresponding week of 1900 only 2597 deaths. The great increase is chiefly in Bengal which returns 3846 deaths—a rise of 1200 over the preceding seven days. The worst districts are Patna (with 1634 deaths), Saran (828 deaths), Monghyr (526 deaths), and Gaya (475 deaths). Calcutta returns 233 deaths—nearly double that of the week

previously. Other districts in Bengal are becoming affected, cases having been reported from Hazaribagh, the Sonthal Parganas, Manbhum, Palaman, Mozaffarpore, Bhagulpur, 24-Parganas, Howrah, and Hooghly. The epidemic is also increasing again in the Bombay Presidency where a rise of 300 deaths is reported. The city of Bombay returns 923 deaths, an increase of 137 over the previous week. Other places in this province still infected are Belgaum (with 226 deaths), Dharwar (44 deaths), Thana (143 deaths), and Surat (24 deaths). The Mysore State returns 267 deaths, the Madras Presidency 124 deaths, and the Punjab 55 deaths. During the past week a fresh development has occurred on the Kolar Goldfields, and the threatening at Karachi reported last week shows that the disease has taken a hold of the city once more. The general mortality in Calcutta is again mounting up. There were 264 cases of plague reported with 233 deaths. It is to be noted that there are now no suspicious deaths reported. This system is more in conformity with the returns of other places and is doubtless required for political purposes. At the same time there continues to be, as there always has been, a certain number of deaths about which considerable doubt must exist, and the return of suspicious deaths is more satisfactory in a medical and scientific point of view. Since the above figures were published it is understood that the daily returns show a still further plague mortality, but the disease is chiefly confined for the present to the northern half of the city.

The general mortality in Bombay city is also mounting up and has now reached a rate of 128·26 per 1000 per annum. The total number of deaths during the past week was 2074—an increase of 133 over that of the previous week. The number of births remains about the same as during the corresponding period of last year, suggesting that the population continues about the same in amount. Other diseases formerly prevalent having decreased the rise of mortality must be more definitely attributed to plague.

Agitation is repeatedly being made to open the portals of the Indian Medical Service to native men qualified with Indian degrees. What the leaders of this movement want is a competitive examination for the Indian Medical Service to be held in Calcutta and open to holders of Indian degrees. In consequence of the shorthandedness of the service the Government have recently offered 20 temporary vacancies to men who hold British qualifications, but it is very doubtful whether any candidates will come forward on the terms offered. This offer is not at all what the memorialists want, and it is, in my opinion, absurd to compare an Indian degree and education with those obtained in the British islands. The feeling in the service is that there are too many natives in it already, so that any further concession in this direction would be undoubtedly unpopular.

Some startling figures recently published show that in almost all the larger cities of the North-west Provinces and Oudh, including Cawnpore, Allahabad, Benares, Meerut, and Agra, the annual death-rate has been heavier since the introduction of a filtered water-supply than in the years preceding its introduction. The mortality of other cities in India has increased rather than decreased under similar circumstances. It is obvious that unless a proper system of surface drainage exists with a regular water-supply the soil must become more or less saturated. Colonel G. M. J. Giles, I.M.S., is disposed to attribute some of the increase to the greater prevalence of malaria due to the formation near every water-tap of pools which he has found to be congenial breeding-places of anopheles. The observations of Captain L. Rogers, I.M.S., on the prevalence of malaria in villages adjoining the city of Calcutta may perhaps be explained in the same way.

The Government of India have recently published an interesting note on the milk of cows and Indian buffaloes. This is based on the work of Dr. Leathes, and states that the milk of the Indian cow corresponds very closely to that of the English one, but in the milk of the buffalo the proteids are in higher proportion and the lactose is in lower proportion than in cow's milk. Buffalo's milk usually contains much more fat also. The mineral matter is about the same. The supervision of the milk-supply of the large cities in India is very unsatisfactory. Some attempt at it has been made in Bombay city, but there is absolutely no control over the large quantity brought in from the surrounding districts and there is no systematic examination of milk to detect adulteration and disease germs. From the filthy habits of the natives and their carelessness in the use of foul water it is obvious that dirty milk of poor quality must be very largely consumed. The effect of this on the general health, especially of children, must be disastrous. The conditions which obtain in Bombay apply to other cities.

The improvements being made in Bombay city have evidently awakened the authorities in Calcutta to the necessity of its improvement also. Notwithstanding the very unsatisfactory state of the finances it is contemplated to raise a loan of Rs.3 547,000 in the course of the year. The estimated expenditure includes Rs 300,000 for new municipal offices and Rs.1,095,000 for the construction of a new market, of *dhobikhanas* (washing places) and of *gowkhanas*, and of five blocks of model houses for the poor.

Feb. 23rd.

THE

ORGANISATION OF THE PROFESSION.

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 742.*)

Formation of Strong Medical Unions at Sunderland and South Shields. — Public-house Medical Clubs. — The Struggle with the Friendly Societies.—A Two Years' Canvass to Recruit Medical Practitioners.—Material Improvements Secured.—Unanimous Action of the South Shields Practitioners.—A Slow but Sure Policy.

THOUGH the action of the County of Durham Medical Union has, so far, been mainly devoted to the interests of the colliery surgeons the grievances of the town practitioners have not been overlooked. This union, it has been fully explained, is of but recent creation and it was materially impossible to take up every question at one and the same time. The creation, however, of local branches has facilitated the dealing with various interests, for what could not be discussed as fully as might be desirable by the central council was very ardently debated by the local branches concerned. Thus the difficulties besetting the town practitioners have been taken in hand, notably by the South Shields and Sunderland branches. They brought forward at the last general meeting of the County of Durham Medical Union, held on Feb. 5th, a resolution, which was endorsed by the council of the Union and embodied in their annual report, recommending that the subscriptions paid by members of friendly societies for medical aid should be raised to 4*s*. per annum. In certain parts of the county it has fallen as low as 2*s*. 6*d*. per head per annum, whereas the charge generally made is 1*d*. per week or 4*s*. 4*d*. per annum, and in some places 5*s*. per annum are paid. Then a very important resolution was passed at this same meeting to the effect that the County of Durham Medical Union should present a request to the General Medical Council asking that body to remove from the Medical Register any practitioner who countenances or encourages canvassing organised by a union or society of working men on his or her behalf. Sir George Philipson was asked to bring this matter before the General Medical Council. It was pointed out at the time that the increasing number of lady practitioners must be taken into consideration and that efforts should be made to bring them into line with the movement, so that they might take their full part in the work of organising the medical profession. It was further decided that no practitioner should henceforth accept the post of medical officer for any new club or friendly society for less than 4*s*. per head per annum.

The Sunderland branch of the County of Durham Medical Union was formally constituted on May 25th, 1899. Dr. J. Murphy of Sunderland was elected President and Dr. Hubbersty honorary secretary. Out of 52 local practitioners 44 were enrolled as members of this branch, and this may be considered a very good beginning. Unfortunately all these members did not show themselves as energetic as might be desired. There has been some falling off and this often happens. The excitement, the enthusiasm caused by a first effort, the very novelty of the undertaking, bring people together, but sometimes those who are most ready to promise support are the least fit to persist in a sustained effort. Nevertheless the branch has shown great activity. It has held from May, 1899, to March, 1901, no less than 21 meetings, with an average attendance of 16 members, not counting, of course, the general meeting and the council

meetings of the county union which assembled at Durham and where the representatives of the Sunderland branch were present. One of the first matters to be taken in hand was the question of what are called "family clubs." This means cases where a weekly payment is made either through the agency of a society or directly to a medical practitioner so as to secure medical aid in case of sickness for any members of the family. The rates of payment at Sunderland were very complex, varying according to the number of children; but, practically, they were much the same as that paid by the miners—namely, 6*d*. per fortnight for the entire family. The town practitioners felt that they should join with the colliery surgeons and insist on this being raised to 9*d*. This end was attained with comparative facility in those cases where the payments are made directly to the medical practitioners. This method of payment without any intermediary constitutes what are called "private clubs." In that case no negotiations are necessary. There is no organisation, no committee to negotiate with. The medical practitioners have simply to inform the persons who make weekly payments to them that such payments will no longer be accepted and that the contract must cease or be altered. But, of course, it is first necessary that all practitioners holding private clubs should act simultaneously and that the alterations proposed should be the same in all cases. To make it all the more evident that such an understanding had been effected by the Sunderland practitioners, the local branch of the County of Durham Medical Union printed and issued a similar private club card for all its members. Consequently, whatever practitioner the subscribers selected they obtained from him the same subscription card and the same terms. The movement, as far as the private clubs were concerned, was entirely successful, and this alone means a very considerable improvement in the position of a large number of the Sunderland practitioners.

There are, however, other difficulties which have not yet been settled. For instance, there is the question of "yearly boxes." These are often held in public-houses. A certain number of persons agree to pay a fixed sum every week and collect this amount at a public-house. Out of this sum they pay a medical practitioner 3*s*. per head per annum for medical attendance in case of sickness and divide the remainder among themselves at Christmas. Such organisations, by bringing men together in public-houses, indirectly encourage drinking, and the medical services given also tend to increase the custom of the public-houses. It is obvious that the dignity of the profession would be best served by the total abolition of the public-house yearly box. In this case to ask that the amount paid to the medical attendant should be increased does not suffice; this should be coupled with the establishment of some method of collecting the money that would not necessitate the calling at public-houses.

The Sunderland branch of the County of Durham Medical Union some time ago approached the friendly societies and urged that the payment should be increased from 3*s*. to 4*s*. a year and that there should be no juvenile lodges, or that when juveniles were enrolled they should pay the same sum as the adults. 27 lodges of friendly societies and seven branches of the boiler makers' trade union agreed to these terms, but this does not represent the majority of such organisations. The remaining lodges recently formed the Sunderland Amalgamated Friendly Societies' Association. They rented a house and imported a medical man, whom they have lodged in this house and employ as their servant. Efforts were made to prevent this intruder from accepting such a post, but they were not successful, so he has been professionally and socially ostracised. Even the medical practitioners who are not enrolled in the ranks of the union have joined in this boycott. No one will consult with him, and should a second opinion be necessary he will probably have to retire from the case. Hopes are entertained that in the course of time the imported medical practitioner will find his position so difficult that he will retire.

At South Shields the organisation of the members of the profession preceded the formation of the County of Durham Medical Union. The latter was, as already related, definitely constituted on Dec. 8th, 1898; the South Shields Medical Practitioners' Association was formally established on March 8th of the same year, but the work of organisation had been going on a long time previously. The mode of procedure differed somewhat from what has been done in most of the other centres. In this case it was determined to win over the approval of all the local practitioners before any formal steps were taken, and this was a task which was fraught with so many difficulties that it took some two years to accomplish it. About 25 years ago a similar attempt had been made which resulted in the importation of an outside practitioner by the friendly societies. At that time the medical practitioners were only paid 2*s*. 6*d*. per head per annum, and they demanded that this should be raised to 5*s*. Though reasonable in the abstract it was not very wise or politic to propose thus suddenly so large an increase. There seem to have been lack of tact and insufficiency of preparation and organisation. Nor was the opinion of the public and the profession as ripe some 25 years ago for such efforts as it is to-day. In any case the movement was a dead failure, and the imported medical practitioners caused the old-established practitioners to lose many of their patients. The memory of this failure was not easily effaced. Whenever proposals were made to form a medical union and to seek to improve the position of the local practitioners the melancholy experience of the past was invoked. Nevertheless, on Oct. 9th, 1896, an informal meeting was held at the infirmary which was attended by the two house surgeons and five practitioners from the town. This small group pledged themselves to use their utmost endeavours so as to bring all the local practitioners together and to establish a strong society. Each would strive to spread the idea among his acquaintances, and Dr. J. H. Hunter was requested to act as secretary to bring them together again when necessary. They also agreed to send an appeal and statement to the medical press. Another informal meeting was held on the 17th of the same month and it was decided to inquire what had been done at Hartlepool, where some of the local practitioners had established a medical service in opposition to the clubs and friendly societies. These early efforts were supported by 12 local practitioners who agreed to the principle and gave all help while doubting as to the possibility of obtaining unanimous support. It was indeed very up-hill work. Thus it was not till the beginning of the year 1898 that the initiators of the movement felt that their task was at last accomplished and that they could count on the unanimous support of all the medical men actually practising in the town. Another informal meeting was held on Feb. 16th, 1898, which was attended by 11 practitioners, and Dr. Alfred Cox came from Gateshead to explain how a medical union might be formed. It was then decided that the time had come to convoke a formal meeting and definitely to constitute a society.

Thus was the inaugural meeting of March 8th, 1898, brought about and it proved a great success. Out of a possible attendance of 34 practitioners no less than 28 were actually present. It was then resolved that a union should be forthwith established, its officials were elected, its objects were discussed, and the committee were appointed and instructed to draw up a set of rules. Within a week's time this task was accomplished. The objects were then defined as follows:—

(*a*) To promote good feeling and *esprit de corps* among the practitioners of South Shields and district.
(*b*) To safeguard the interests of the profession generally, and its own members in particular.
(*c*) To discuss medico-ethical and kindred topics affecting the profession.
(*d*) To form and issue a black list of habitual bad payers for the use of members only.

Two members of the committee made some objection to the proposed black list, but finally they came round to the views of the majority, so that the "objects" and the rules were unanimously adopted.

The title selected, as already stated, was that of the South Shields Medical Practitioners' Association which comprises all registered medical men residing, or having consulting-rooms, in the county borough of South Shields and the villages of Whitburn and Boldon. The subscription was only 5*s*. per annum and at least four general meetings were to be held in the course of the year. It was under the heading of "expulsion of members" that the most important rule was drawn up—namely:

In the event of this association agreeing to take combined action any member found guilty (after full discussion and ballot) of gross breach of faith shall be expelled from the association and professionally ostracised by the members of the association.

It was, however, agreed that no member should be expelled unless by a majority of two-thirds, not of the members present, but of the entire association.

This is the one disciplinary rule, the one weapon for enforcing the decisions agreed upon. On March 26th another general meeting was held which was attended by 23 out of the 34 medical men in practice at South Shields, and these rules as drawn up and recommended by the committee were adopted. Thus, and though it took some two years to prepare for the formation of the association, this preparation was so full and elaborate that when at last the formal steps were taken the support given was unanimous and everything was accomplished and organised in less than three weeks. All the old feuds and animosities between some of the practitioners in the town had been smoothed over, old enemies were now fast friends, and this happy uniting of the profession manifested by the official formation of the association was celebrated by a dinner held in the following month at which 21 members attended. The fact that on March 8th 28, on March 26th 23, and for the dinner on April 15th 21, out of the 34 medical practitioners were able to attend is very significant. At the most pleasant gathering, the dinner, there was the smallest attendance; to the most important meeting, when it was necessary to show a united front so as to form the association, there came the largest number. This illustrates the earnestness felt in the cause, and is truly encouraging.

In June, 1898, a general meeting was held to discuss the question of fees for certificates and emergency cases. The feeling was that certificates were constantly required for all manner of purposes other than the objects of the society which employed a medical officer. Therefore it was resolved that if a person wanted to join a friendly society or a trade protection society that did not employ a medical officer he should be charged 2*s*. 6*d*. for a health certificate. If such societies did employ a medical officer, then such medical officer was in future to charge 1*s*. for a certificate. Sick and health certificates given for other than lodge purposes were to be charged 1*s*. each. The point is that a person is often insured in several societies and only one of these societies employs a medical officer. It is not fair to obtain from that medical officer certificates needed by the other societies which do not employ him.

The first annual meeting was held in October, 1898, and 24 members were present. The report then submitted showed that the number of practitioners in and about the town had increased and consequently there were now 38 members of the association. The working expenses had been so slight that though the subscription was only 5*s*. the balance in hand was £3 13*s*. 8*d*. The late Mr. R. B. Anderson of the Corporate Medical Reform Association gave an address explaining the object of this organisation and 17 members joined this body after the South Shields Medical Practitioners' Association had passed a resolution approving the policy of the Corporate Medical Reform Association. At the general meeting held in November, 1898, it was resolved that the resolution in regard to certificates should come into force on the following Jan. 1st. It was also decided that no new friendly or trade society should be accepted for less than 3*s*. 6*d*. per head per annum. That this should be considered a great improvement shows to what a low ebb contract work had fallen. A penny per week, or 4*s*. 4*d*. per annum, should be the minimum, but nevertheless 3*s*. 6*d*. is a considerable improvement on the 2*s*. 6*d*. usually paid at South Shields. The meeting having heard of the efforts that were then being made to form the County of Durham Medical Union passed a resolution expressing their sympathy and approval. It was also decided to extend the field of action of the South Shields Medical Practitioners' Association to the neighbouring districts of Jarrow and Hebburn. The 10 medical men practising in these localities were willing to join, there would be no outsiders, and perfect unanimity would prevail. On the other hand, this would so increase the size of the ground covered by the association that it was necessary to subdivide it into districts with a "whip" for each district. Now followed the second annual dinner which was attended by 31 members and five visitors, and this large attendance shows how the association had increased in numbers and strength.

During the winter and the beginning of the following year the County of Durham Medical Union gave proof of its vigour, for it was engaged in several notable struggles, and as South Shields is in this county the question of affiliating with the more general movement was raised. After some discussion the affiliation was voted on March 14th, 1899, when another general meeting was held. This meant that the members of the South Shields Medical Practitioners' Association would have to pay 10*s*. 6*d*. instead of 5*s*. per annum and would not be able to keep their own money for themselves—that they would have to send it all to the treasurer of the county union at Durham. They would only receive back from the central council representing the county such sums as were judged necessary to cover their local working expenses. Considered from a purely narrow, local, and selfish point of view such affiliation did not seem a very advantageous transaction, but from the more philosophical, more generous, and broader point of view it was certainly the true policy. Local organisation, however successful, will always be endangered from the outside. A locality is as a larger individual, and if union is necessary in a locality between individuals the union of different localities with each other is equally necessary. So, the South Shields Association is now a branch of the County of Durham Medical Union. The benefits of organisation made themselves felt more and more as time went on. Thus, in May, 1899, a lodge changed hands and the rule came into force that no one was to accept a new appointment at less than 3*s*. 6*d*. The members of the lodge called on all the practitioners available offering the old terms of 2*s*. 6*d*., and they all refused, and thus the increase had to be given. No medical practitioner tried to underbid his colleagues; the formation of a union has put an end to any such modes of competition. On June 1st following the South Shields practitioners raised their charge for private family clubs from 6*d*. to 9*d*. per fortnight per family. They employed collectors, paying from 10 per cent. to 15 per cent. commission on the amounts collected, and gave them instructions not to accept less than 9*d*. and to strike off all those who would not give this amount. In the same manner as at Sunderland uniform subscription cards were printed for all the practitioners, so that wherever the subscribers went, from one end of the town to the other, every practitioner gave them the same card and offered them the same terms—there was no alternative left open. Before this uniformity of action on the part of the profession the public yielded at once. In the same way and with equal facility the midwifery fees have been raised from 10*s*. 6*d*. to 15*s*. These two items alone, the midwifery fees and the raising of the family private clubs from 6*d*. to 9*d*., have sufficed to increase the income of some practitioners in the town to the extent of about £100 per annum. Then it has also been resolved to apply a wage-limit in regard to family clubs and not to accept as members of such clubs any family where the principal wage-earner receives more than 35*s*. a week. On examining the prevailing rates of wages in the neighbourhood this was found to be the frontier line between the skilled and unskilled worker. As a matter of fact, very few men earn exactly 35*s* a week. Carpenters generally make 38*s*. and riveters 45*s*., whereas on the other side of the scale labourers often do not earn 20*s*. a week, and it is for the latter that family clubs are intended. The third annual meeting was held on Nov. 26th last and it was then determined to take in hand the question of hospital abuse. A committee to inquire into the matter was appointed. It was then also reported that at two collieries in the immediate neighbourhood of the town the increase to 9*d*. per fortnight had been granted, but that the men at a third colliery had imported a surgeon and at first only paid him 6*d*. per fortnight. After he had been on the spot for a little while he also suddenly refused to continue any longer working for so small a sum and insisted on the 9*d*. The miners, in face of this defection, had now yielded and were paying the sum required. One of the South Shields practitioners who had attended the miners at a neighbouring colliery had incurred some loss in consequence of this struggle, but was now regaining his old position. All these details indicate that genuine progress has been made. The methods adopted were very circumspect and prudent. Each step was taken only after elaborate preparation. No sweeping or sudden reforms were attempted. Slow and sure was the policy. This policy may have lacked in brilliancy, it may not have satisfied buoyant and impatient ambition, but it has brought about substantial improvement without necessitating any great risk or sacrifice. On the other hand it has left many grievances and abuses still unreformed and therefore there is yet much work to be done in the future.

South Shields.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool Country Hospital: a Munificent Donor.

THE second annual meeting of the subscribers to the Liverpool Country Hospital for the Chronic Diseases of Children was held in the Town Hall on March 4th, under the presidency of the Lord Mayor. The report stated that the children admitted to the institution were the subjects of diseases requiring a prolonged period of treatment in the country, whether medical or surgical, for their cure, and an essential qualification for admission was an opinion that a reasonable hope of cure existed. The hospitals in the city deal only with acute cases, and cannot meet this necessity. During the past year the applications for admission had been considerably in excess of the available accommodation; the 20 beds rented from the children's convalescent home at West Kirby had proved quite inadequate. The result of the year's work had been highly satisfactory, 12 out of 14 cases discharged having been cured. Of the 20 patients admitted when the hospital was opened 10 were still under treatment. The number of cots available for new cases had been very limited. It was gratifying that the committee had been able to acquire a suitable site at Heswall comprising nine acres, at a cost of £2500, upon which a hospital will be erected which would accommodate a largely increased number of children. The amount required to build the hospital would be £20,000, and a generous donor had come forward offering to contribute £5000 provided that three other donations of the same amount were forthcoming and that a further sum of £10,000 in any amounts should be raised as a maintenance fund. The gentleman who has made this offer wishes to remain anonymous, and makes a stipulation that the above amounts shall be raised by June 30th next. Mr. Holbrook Gaskell has added to his previous benefactions by sending £1000 to the fund. Mr. Alfred L. Jones also announced his intention of contributing £500, and the committee made an earnest appeal for funds to meet the conditions of the generous anonymous donor. There can be no doubt that the hospital has supplied a want long felt and the benefits of treatment aided by pure country air were warmly advocated by Dr. William Carter and Dr. Richard Caton at the meeting which was influentially attended.

The City Council and Workmen's Dwellings; the Prevalence of Measles in, and the Absence of Small-pox from, the City.

The housing committee of the City Council has been active in visiting several sites in the north, south, and central areas of the city to consider the requisite improvements for the erection of workmen's dwellings. A special committee has been appointed for the preparation of a scheme to give effect to this object. The medical officer of health (Dr. E. W. Hope), in his report to the health committee on Feb. 28th, regretted the continued prevalence of measles, of which he saw no signs of decrease, the number of deaths registered during the week from that cause being 31. A considerable number of schools had been closed, which had the effect of removing centres of infection. The disease was practically confined to the north and east areas of the city. Fortunately there was not a single case of small-pox reported during the week prior to the last meeting of the health committee (March 7th).

The Lord Mayor's Hospitals Century Fund.

The Lord Mayor has already received more than half of the amount for which he appealed to liquidate the indebtedness of the local charities. He has, in consequence, been enabled to distribute to the charities at the rate of 10*s.* in the pound. The Royal Southern Hospital received £2070, the David Lewis Northern Hospital £1881, the Royal Infirmary £1695, the Stanley Hospital £918, and the Liverpool dispensaries £620. Smaller amounts, bringing up the total to £10,126, were apportioned to the remaining charities.

March 12th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Cottage Homes.

FOR some years past the principal boards of guardians in Glamorganshire have provided cottage homes for the children admitted to their workhouses. Their establishment has been attended with noticeable success at Bridgend, Swansea, Cardiff, Pontypridd, and at Neath, where additional houses are about to be erected at a cost of over £7000. The cost of these isolated dwellings with their increased staff is probably a little higher than that of one large building; in Cardiff it is said to be 9*s.* 4½*d.* per head weekly. The homes at Pontypridd were erected in 1892, and there are now occupied eight cottages, in each of which there is accommodation for 20 or 22 children of both sexes and of varying ages. The care of the household is entrusted to a foster-mother who is assisted only by those children in the home who may happen to be old enough to render assistance. Each house is self-contained, the meals being cooked and partaken of in the separate homes. In two of the cottages the foster-mother is married, the husband in one case acting as gardener and in the other as shoemaker, the boys receiving training in both these callings, and one cottage occupied by elder girls has a laundry attached to it. The children of school age attend a school within the grounds of the institution.

Swansea Workhouse.

Reference has already been made in this column (March 2nd, p. 668), to the re-arrangement of the Poor-law appointments at Swansea. The board of guardians have now decided to appoint a medical officer for the town district at a salary of £150 per annum and £10 as consulting medical officer to the workhouse, together with the vaccination fees, which are estimated to amount to an additional £300 yearly. The medical officer to the workhouse is to be paid a salary of £200 per annum, which sum is to include extra medical fees. The guardians will supply all medicines, but the medical officer is to bear the cost of all spirituous liquors that he may order. This last stipulation is surely a distinct innovation.

Arsenic in Beer.

In a recent report of the analyst to the county of Glamorgan it is stated that among a large number of samples of beer and brewing materials submitted for examination for arsenic in only one instance was any contamination found, and that was in a sample of beer from Merthyr, where arsenic was detected in amount equivalent to one-sixth of a grain of metallic arsenic per gallon. The analyst (Mr. Clarence Seyler) in the same report refers to the possibility of arsenic being found in beer brewed from malt, and in which glucose has not been used, owing to the malt having been dried by arsenicated coke. Mr. Seyler states that he has examined samples of coke made from Welsh coal and finds that while the best qualities are free from arsenic, in other varieties he has found it present in an appreciable amount up to one-twentieth of a grain per pound.

Health of Neath.

Mr. James Elias, the medical officer of health of the borough of Neath, in his report for the year 1900 records a death-rate of 19·1 per 1000 and the high infantile mortality rate of 179 per 1000 births. There were epidemics of measles and of typhoid fever in the town during the year.

West Cornwall Women and Children's Hospital, Redruth.

The annual meeting of the subscribers of this charity was held on March 6th. The medical report showed that 142 in-patients had been admitted, 110 of whom were women and 32 were children. The average stay in hospital was 30 days for women and 47½ days for children. The average cost per head, including staff, amounted to £28 16*s.* The financial statement showed that the total expenditure was £505 and an adverse balance of £43 remained.

Bath Workhouse.

At the meeting of the Bath Board of Guardians held on March 6th a letter was read from the medical officer of health (Dr. W. H. Symons) inclosing a copy of a communication which he had addressed to the Local Government Board complaining of being refused admission to the workhouse to investigate the outbreak of an epidemic among children there. The master stated that he acted in accordance with Article 214 of the Local Government Board Orders in instructing the porter to admit no one except the officials of the board without the authority of the guardians. Eventually the guardians decided to send an explanation of the circumstances to the Local Government Board.

March 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Glasgow Small-pox Epidemic.

THE position on the whole is showing signs of improvement, but is yet far from being satisfactory. There are still 435 patients under treatment in hospital, and the new cases number as a rule from 10 to 15 daily. The death-roll is now 167. The authorities continue to display unabated energy in their endeavours to check the epidemic, and a somewhat querulous tone which had begun to manifest itself in public criticism is now less evident. Dr. A. K. Chalmers, on behalf of the Health Committee, has addressed a circular letter to all medical practitioners throughout the city inviting their further coöperation in promoting revaccination. The letter proposes to divide the city into districts based on the census enumeration scheme for the purpose of organising a systematic house-to-house visitation. It is hoped that a sufficient number of practitioners will volunteer to conduct evening visits in each district so that the necessity of submitting to revaccination may be urged with the sanction of professional advice on every person not yet revaccinated. For each vaccination so obtained the modest fee of 2*s.* 6*d.* will be paid. As was to be expected the public spirit of the profession is proving equal to the occasion, and a meeting of medical men who have accepted the conditions of the circular is to be held at an early date to organise the details of the scheme. Councillor J. T. Biggs from Leicester has appeared on the scene and has spoken at a public meeting, which he persuaded to give an endorsement to a proposal that he should receive full liberty to visit the small-pox hospital. Bailie Stevenson, who was present, expressed his approval of the proposal, but the resolution when forwarded to the Lord Provost received a reply which will hardly invite further requests of the same nature. The local press has had the advantage of some vigorous comments on the "Leicester system" from the pen of Dr. Francis T. Bond, the honorary secretary of the Jenner Society, and the conditions generally hardly favour the progress of the anti-vaccination crusade.

A Dispensing Mistake.

An unusual case has recently occupied the attention of the Court of Session, in which a Glasgow commission agent sought to recover damages from a firm of druggists for a mistake made in dispensing a prescription. It seems that the pursuer left at the defendants' shop a prescription for some medicine to be taken internally, and that after this had been dispensed a bottle containing liniments of aconite and belladonna was by mistake given to a messenger who delivered it at the pursuer's office. The pursuer, without completely unwrapping the bottle, which was accurately labeled and marked "poison," at once proceeded to take a dose. Becoming suspicious that something was wrong he went back to the druggist to complain, taking with him the poisonous liniment. The druggist's assistant, though admitting that a mistake had been made, treated the matter somewhat cavalierly, not believing, as he said in court, the pursuer's statement that he had actually swallowed a dose of the liniment. When the pursuer reached home he became very ill and was for some time under medical treatment; he therefore sued the firm of druggists for compensation. It was pleaded in reply that the pursuer had been guilty of contributory negligence inasmuch as he had failed to remove the wrapper from the liniment bottle and had thus neglected to take proper precautions for his own safety. The Lord Justice Clerk in summing up made some strong remarks on the manner in which the pursuer's complaint had been met by the druggists' assistant and the jury found for the pursuer and assessed the damages at £700.

Glasgow University.

The preparations for the celebration of the ninth jubilee of the University are being steadily advanced. The ceremonies are to be on a highly elaborate scale and every effort is being made to render the whole undertaking a great success. It is hoped that one result will be a large addition to the fund to be raised for increasing the laboratory facilities of the University. Some substantial contributions have already been obtained and the sum promised now reaches some £25,000.—The death of Dr Dickson, emeritus professor of divinity, will be keenly regretted by many graduates, his picturesque figure being well known in the quadrangles, and members of all the faculties were his debtors for long years of service he gave to the University library.—The death of Dr. C. E. Foucart Scanlan will also touch the sympathies of Glasgow graduates of 10 to 15 years ago. Dr. Scanlan practised for some years in Australia, but he recently volunteered for colonial service on the West Coast of Africa. While on the voyage out he unfortunately succumbed to an attack of sunstroke.

Death of Dr. John R. Black of Greenock.

The intimation of the death at the comparatively early age of 51 years of Dr. John R Black has caused general regret in Greenock and the neighbourhood where he had gained a secure position in professional and public esteem. Dr. Black was a graduate of Edinburgh University and for some years acted as one of the surgeons to the Greenock Infirmary. More recently he interested himself to secure the establishment of a children's convalescent home, but unfortunately he has not lived to see the completion of his labours. His death took place on March 10th at Biskra, Algeria, where he had gone for a holiday with a view to re-establish his health.

Aberdeen Dispensary.

At the annual meeting of the supporters of the Aberdeen Dispensary, Maternity Hospital, and Vaccine Institution held on March 6th it was reported that the total number of cases treated during the year was 11,801. The ordinary and zymotic cases numbered 9235 and vaccinations 141. The new maternity hospital in Castle-street was described by the Lord Provost as a "splendid house." Five of the medical officers were re-elected, and for the vacancy caused by the resignation by rotation of Dr. A. T. Gordon Beveridge Dr. John F. Christie was appointed by a majority of votes.

The Hospital for Sick Children, Aberdeen.

The ordinary expenditure last year amounted to £3486, and the ordinary income to £1808, leaving a deficiency of £1678, reduced by legacies to £878, and an appeal for more liberal subscriptions has been issued.

March 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The University Question in Ireland.

IN order to carry out the objects aimed at in the resolution of the Senate of the Royal University of Ireland passed some time ago an influential deputation, introduced by Lord Morris, waited on his Excellency the Lord Lieutenant on March 9th for the purpose of asking that a Royal Commission might be appointed to inquire into the relations of that University with the other teaching bodies and with its own students. His Excellency's reply proved a happy surprise even to the members of the deputation. He said that after consultation with his colleagues an inquiry would be granted immediately and that it would assume the shape of a Royal Commission to inquire into the matter of university education in Ireland. He added, however, that the inquiry would not include any investigation into the condition, circumstances, or special work of Trinity College, Dublin. It will be noted that the field to be covered by the Royal Commission promised by his Excellency is far wider than was asked for or at all anticipated. It will probably prove of the greatest possible importance in connexion with the solution of the whole Irish University question.

Queen's College, Belfast.

Lieutenant-Colonel Moorhead, late of the Indian Medical Service, has been appointed by the College Council lecturer on tropical diseases, a department established at the suggestion of the Colonial Secretary.

Hospital for Diseases of the Nervous System, Belfast.

At the fourth annual meeting of this hospital held on March 8th it was reported that 473 patients had been treated during the year, as against 377 in the previous 12 months. On the first of this year wards for in patients were added, the hospital hitherto having been for out-patients only. The hospital has also been purchased from the ground landlord. At the conclusion of the meeting an "at home" was held in order to let the friends of the charity inspect the new wards.

North of Ireland Branch of the British Medical Association.

A meeting of the members of the North of Ireland branch of the British Medical Association, specially summoned to consider the report of the Constitution Committee, was held in the museum, Belfast, on March 8th. The President (Professor John W. Byers), who occupied the chair, gave a *résumé* of the details of the new constitution as proposed by the committee specially appointed at the last annual meeting of the Association at Ipswich. An interesting discussion followed, at the conclusion of which Lieutenant-Colonel Moorhead, moved, and Mr. G. L. St. George (Lisburn), an ex-President of the North of Ireland branch, seconded, a proposition, which was passed unanimously, approving of the recommendations of the Constitution Committee.

Dr. Alexander Dempsey on Irish University Education.

Dr. Alexander Dempsey, senior physician to the Mater Infirmorum Hospital, writes a very interesting letter to the *Belfast Irish News* (the organ of the Roman Catholics of the North of Ireland) of March 9th, pointing out that those who expect the Roman Catholics of Belfast and the north of Ireland generally to be satisfied with the endowment of a college in Dublin to supply all their requirements for university education know little of the feeling of the people. He says that the Roman Catholics of Belfast will not send their sons to Dublin where they have no friends or business relations of any kind. He points out the sacrifices made by Roman Catholics in the north of Ireland in order to be consistent and obedient to the teaching of the Church which made the restrictions against Roman Catholics attending the local Queen's College more severe than those in operation at Cork, Galway, or Trinity College, Dublin. Should the Roman Catholics of Belfast be ignored in the settlement of the university question Dr. Dempsey thinks the local bishop will have no easy task in preventing them from attending the Queen's College. If the Roman Catholics of Ulster are to be left out of any settlement, Dr. Dempsey says, let a University of Ulster be established and a Catholic endowed college as well, and let the latter with the Belfast Queen's College be equally represented on the Senate of the Belfast University. The Roman Catholics of Belfast and the north of Ireland have built an admirable new hospital in Belfast; they are also arranging to establish a medical school (in fact, their hospital is now recognised by the Royal University), and most naturally they demur to any arrangement of the university question which would tend to complete centralisation in Dublin. They believe, and many think most fairly, that the Roman Catholics of the north are quite entitled to obtain their medical education at home without going to Dublin. They see that continued centralisation of educational matters in Dublin is really causing no advantage, but the contrary, to the general inhabitants of Ireland, and that, even looking at the question of the advancement of the science of medicine, centralisation tends to stagnation.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

New Chairs in the Faculty of Medicine of Paris.

THE Municipal Council has just created two new chairs in the Paris Faculty of Medicine, the one of Clinical Gynæcology and the other of Clinical Surgery of Children. It is some two years since the project was first set on foot and the council voted 2000 francs as the endowment for each chair. Things, however, went no further owing to it being found impossible to decide as to who should be called to occupy the chairs. This year the subject has come up again and the nomination of the professors has been confided to 10 members of the Municipal Council and 12 representatives of the University, among whom are the dean and assessor of each of the three faculties and an additional assessor for the Faculty of Medicine. M. Pozzi was nominated for the chair of Gynæcology by 12 votes, as against five given to M. Bouilly and four to M. Second. M. Kirmisson was nominated for the chair of Clinical Surgery of Children by 13 votes in the third ballot as against nine votes given to M. Brun. The names will have to be submitted for ratification to the Minister, but there is little doubt as to his decision.

The Sanitary Condition of the Andral Hospital.

At the meeting of the Hospitals Medical Society held on Feb. 22nd M. Mathieu complained of the overcrowding and the grossly insanitary conditions existing at this hospital. Not only the patients but the nurses and visitors were affected by the want of air and by the abominable smells. The patients were very closely packed and those suffering from pneumonia lay on mattresses placed on the brick flooring of the wards. Owing to these conditions contagious affections multiplied exceedingly; for instance, all the patients in a low state of health suffered from thrush. M. Joffroy, M. Siredey, and M. Hirtz backed up M. Mathieu in his complaints and added some of their own. M. Faisans remarked that there were 1700 patients too many in the Paris hospitals, which was owing to the fact that a great number of persons were admitted who had no right to be so. On the other hand, it was impossible to increase the number of beds in the infirmaries (*lits d'hospice*) so as to relieve the pressure on the hospitals for want of funds. M. Mathieu suggested that a minimum cubic air space for every patient should be insisted upon. In barracks the minimum was 17 cubic metres per man and in military hospitals 40 cubic metres per patient.

The Bretonneau Hospital.

This new hospital which is devoted to sick children was opened on March 1st. The site contains 13,000 square metres and the buildings are of yellow brick ornamented with tiles which have a very bright appearance. The roofs are covered with coloured tiles. The various blocks are as follows: the first contains the rooms of the director and the house physicians and surgeons, administration offices, waiting rooms, and medical and surgical consulting rooms. In the second are the dispensary, the kitchens and offices, and a dining-room for the nurses. The remaining blocks are for wards, including isolation wards. The fittings of all these buildings are in accordance with the latest views upon hospital architecture and all angles made by the walls with the floors or ceilings are rounded. At the end of every ward is a kind of lobby well lighted and ventilated and furnished with a table and chairs where the little patients who are able to be up but not well enough to be out of doors can get up their strength after being in bed. Every ward has a bath-room with two baths, one fixed and the other moveable, the latter being for bedridden patients. There are three operating theatres fully fitted up and lighted with electric light. There is a lift and the warming of the buildings is done by steam. The isolation wards are fitted with glazed cubicles so that the children can see the goings-on in the ward from their beds although completely isolated. The lay staff of the hospital, including the nurses, numbers 125 persons. On the opening day the new hospital took in 40 surgical patients from the Tenon Hospital where they were being treated. The medical wards were to open about March 10th, but the dispensary is not quite ready yet.

Alcohol and the Army.

Last year General Gallifet, the then Minister of War, issued an order forbidding the sale of alcohol in barrack canteens. General André, the present Minister, has just issued another order to corps commanders on the same subject. "The order of last year," he says, "will give good results as regards the prophylaxis of alcoholism in the army. But seeing that the abuse of alcohol is always practicable in other places than barracks the order will do but little good unless by means of moral action exercised by the officers the men are convinced that alcohol, so far from giving them strength, diminishes their powers of resistance both to fatigue and disease." As a result of this opinion the Minister has decided that lectures are to be given to the various corps either by officers or by army surgeons upon the dangers and effects of alcohol, while at the same time a course of elementary lectures on hygiene is to be given. These two circulars have not, unfortunately, had such a good effect as was expected owing to the want of surveillance exercised by the officers, a want generally due to the complaints of the *cantiniers* about the monetary loss which they sustained, the sale of "nips" being their principal source of income. The artillery canteens in the north were particularly affected. The colonel of one of these regiments, however, hit upon the happy idea of trying milk and the results exceeded all expectation. The first day eight glasses were sold. Eight

days later 15 litres were sold in a morning and at present 80 litres are barely enough, without counting the sale of *café noir* and chocolate made with water.

The Treatment of Inoperable Tumours.

This subject, which comes up periodically for discussion at the various societies, has of late had special attention drawn to it. M. Wlaieff has been making experiments in the hospitals with a serum obtained from birds previously inoculated with the cells of blastomycetes obtained from human cancerous tissues. M. Berger and M. Lucas-Championnière have previously laid before the Academy of Medicine the results of some observations made upon patients with inoperable growths with this serum, who have improved in a very remarkable manner both as regards local conditions and also as regards their general health. Actual cure, however, was not obtained. M. Reynier has again brought the subject before the Society of Surgery. Using the serum he found that in a certain number of cases pain disappeared very rapidly, the patient's general condition improved, and the growth diminished in size, but did not altogether disappear. The results are much the same as those obtained some years ago under the use of the anti-cancerous serum of M. Richet and M. Héricourt. On the other hand, experiments made upon animals show that Wlaieff's serum has no appreciable effect when the lesion is generalised. M. Picque, in a case in which a malignant growth of the jaw recurred after operation, found that in spite of injections of Wlaieff's serum metastasis rapidly took place and that the injections apparently made the tumour grow. M. Bazy reminded the meeting that cancerous tumours sometimes disappeared without any anti-cancerous treatment, a fact which he had noticed in a case of cancer of the breast with secondary growths in the vertebræ. M. Berger, in resuming the discussion said that the improvement which followed these injections was to his mind unquestionable, and the treatment was certainly deserving of a trial in those cases where the surgeon felt unable to operate. He had seen most striking improvement occur in all the symptoms, but he had never seen the growth vanish completely. At the same meeting M. Launois referred to some remarkable results obtained by Jaboulat's method of hypodermic injections of quinine. The case was one of cancer of the breast. Glands were involved both in the axilla and the supra-clavicular region. There was marked cachexia and the patient suffered severely. She could neither eat nor sleep and the growth had obviously extended to the vertebræ, in fact she was dying. After being treated for two months with injections of quinine hydrochloro-sulphate given every two days in doses of 50 or 60 centigrammes the results were something marvellous. The ulcer healed up and the breast had almost regained its shape, the glands were no longer to be felt, the patient who had been absolutely bedridden was going about, had no pain, slept well, had regained strength, and had put on flesh. This improvement was maintained although the treatment had been left off for a month. These facts are worthy of every attention for in quinine we have a therapeutic agent whose parasiticidal action is known.

(FROM OUR OWN CORRESPONDENT.)

Anæsthesia produced by Intradural Injections in the Lumbar Region.

SOME time ago Professor Bier of Greifswald made the important discovery that an injection of cocaine into the lumbar arachnoid caused a total analgesia of the lower extremities and of the abdominal and lumbar surface as far as the mammary region. Experiments were made on Professor Bier himself, on his assistant, and on five patients, the result being that a dose of from 0·005 gramme to 0·150 gramme of cocaine was found to produce analgesia, which began in from five to 10 minutes and lasted about three-quarters of an hour, so that operations on the lower extremities could be performed without the use of any other anæsthetic. Some disagreeable after-effects were experienced, such as headache and vomiting, but there were no grave complications. This method has been tried by several surgeons. Professor Seldowitsch of St. Petersburg has performed operations on the lower extremities of four patients under total analgesia produced in this way, but it was attended with some rather disagreeable symptoms. All the patients some hours afterwards complained of a feeling of intense cold, their temperatures rose to about 40° C. (104° F.), and they also suffered from headache, giddiness, vomiting, and in one instance also meiosis. All these complications disappeared by next day. Professor Tuffier of Paris obtained very favourable results as regards the analgesia, but the above-mentioned complications were present in his cases also. In a paper read before the International Congress of Medicine in Paris he said that he had used the method in 126 cases, the anæsthesia beginning with prickling and formication in the lower extremities which was followed by a feeling of great anxiety, epigastric oppression, vomiting, cold perspiration, and acceleration of the pulse. The symptoms disappeared after 24 hours and were not serious so that Professor Tuffier recommended the method as available for surgical operations. Two other surgeons, Dr. Severeanu and Dr. Racoviceanu of Bucharest, stated in the discussion that they had given lumbar intradural injections of cocaine in 70 and 125 operations respectively. The last-named gentleman found that some disagreeable symptoms, including syncope, were produced in his patients, so that he thought general narcosis by chloroform was preferable. By experiments on animals Dr. Nicholetti of Naples ascertained that cocaine did not produce any alterations in the nerves or the medulla, but that its action was merely vaso-motor; other substances such as ergotin, quinine, and antipyrin, when injected into the lumbar arachnoid had the same effect. Professor Bier himself, in a second communication published in the *Münchener Medicinische Wochenschrift*, states that his method is too dangerous to be generally used and he warns surgeons not to inject more than 0·015 gramme of cocaine. He hopes, however, to be able very soon to recommend injections of another anæsthetic devoid of poisonous action by which analgesia will be produced not only in the legs but also in the trunk and the upper extremities. Injections of eucaine proved useless. Dr. Engelmann of Bonn had 0·010 gramme of this substance injected into his own lumbar arachnoid, the effect being that all the same disagreeable complications of vomiting, fever, dyspnœa, &c., appeared as with cocaine, but the analgesia was very incomplete. Much better results were obtained with tropacocaine. Dr. Schwarz of the hospital at Agram, writing to the *Centralblatt für Chirurgie*, has stated that he has injected this new drug in 16 cases. He began with a dose of 0·015 gramme, gradually increased to one of 0·050 gramme. In no instance did any of the complications produced by cocaine make their appearance. Injections of 0·030 gramme were followed by analgesia extending from the feet to the knees; with stronger doses a more extensive region was affected; with an injection of 0·040 gramme Dr. Schwarz was able to remove a sequestrum from the femur and to operate on several cases of hernia without any pain to the patient. With injections of 0·050 gramme operations of two hours' duration were performed. The general health of the patients was not at all interfered with, and the analgesia appeared in 10 minutes after the injection. Dr. Schwarz was therefore of opinion that the use of tropacocaine by Professor Bier's method will ultimately become the ideal method of producing anæsthesia. Memoirs on the production of anæsthesia by injection of cocaine into the lumbar arachnoid during labour were read last year before the Paris Academy of Medicine by M. Doléris and M. Malartic,[1] whose attention had probably been directed to the subject by the publication of Professor Bier's discovery.

German Military Hospitals in China.

The *Deutsche Militärärztliche Zeitschrift* has published a letter from Surgeon-General Dr. Krosta, the chief medical officer to the German forces in China, dated from Tientsin, Dec. 12th, 1900. He stated that four military hospitals, with about 1000 beds, had been established in Tientsin. Tientsin University was converted into a hospital, for which purpose it was structurally well suited, the wards being large and well ventilated. The arrangements were as complete as in any well-equipped hospital in Europe. There were hygienic, chemical, bacteriological, and radiographical

[1] THE LANCET, August 11th, 1900, p. 465.

laboratories, a dissecting-room, and even a dental department which was very much resorted to. All these institutions were under the care of specially trained medical officers. There were two rooms for operations of which one was provided with electric light. There were also military hospitals for the garrisons at Peking and Paotingfu. A home for convalescents has been established at Kobe, Japan, by the German Red Cross Society. Dysentery and enteric fever had been prevalent, but the former was disappearing whilst enteric fever was becoming rather malignant. The health of the troops was generally satisfactory, the sick being on an average 5 per cent., but among the marines the proportion was much greater. Scientific work was not neglected, and the hospital reports were being collected for publication after the cessation of hostilities. A German medical society had been founded under the presidency of the chief medical officer.

March 11th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Operations on the Upper and Lower Jaw.

ON Feb. 2nd Professor Carl Schlatter spoke in the Zürich Medical Society on this subject. The dangers of the aspiration of blood during operations on the maxilla can be avoided by incomplete narcosis, which, however, is most distressing to the patient, makes the operation much more difficult, and necessitates more haste than is desirable in the case of removal of malignant tumours. Professor Schlatter recommends preliminary compression or ligature of the external carotid if necessary, also of the internal carotid artery, especially in the case of anæmic patients, who, however, should not be suffering from arterio-sclerosis. At the same time this gives the operator the great advantage of removing metastatically diseased glands, which first appear along the carotids and are often overlooked. This latter fact explains the high percentage of recurrence of malignant tumours of the upper jaw. The direct (immediate) mortality of the operations of resection of the maxilla is already very high—from 14 to 31 per cent. (Bryant, Martens)—so that the results in the Zürich surgical wards seem especially satisfactory, there being only one case of death on record out of 34 cases of total resection of the upper jaw for malignant tumour; but the proportion of recurrence is high—König reports 33 out of 47 patients and the Zürich clinique 23 out of 34 cases. Professor Schlatter, speaking of three cases which he successfully operated on, prefers either temporary ligature of the common carotid artery with thin indiarubber tubing or permanent ligature of the external carotid, the hæmorrhage during operation being thereby greatly reduced. Dr. Stoppani, dental surgeon of Zürich, supplied the patients with excellent protheses which corrected both prolapse of the bulb of the eye and deficient speech. Professor Schlatter showed a girl, aged 17 years, from whose mandibula he resected some three inches for myelogenic sarcoma occurring six and a half years ago. After the operation he introduced a "prothèse immédiate" and a month later a definite prothesis made of gutta-percha and surmounted with false teeth; this prothesis, which fitted perfectly and could be taken out and cleaned after meals, had to be renewed four times in six years, corresponding to the growth of the skeleton. The present functional and cosmetic result is perfect: only a slight cicatrix on the outside of the jaw indicates the line of operation, and speech and mastication are both satisfactory. Dr. Stoppani's prothesis with perforated metal side splints proved most valuable; it makes the surgeon independent of the dental surgeon during and immediately after the operation, the chin does not retract, the wound can be kept antiseptically clean, and a cast can be made without more than a short removal of the "prothèse immédiate" from which the definite prothesis can be constructed.

Wounds of the Eye.

On Feb. 23rd at a meeting of the Medical Society of Zürich Professor Haab read a paper on Wounds of the Eye. These wounds are frequent and of practical importance, as the primary treatment greatly influences the prognosis. Of 12,958 patients who attended the out-patient department of the Ophthalmological Clinique during three years, 182, or 1·4 per cent., had perforating wounds of the eye, and 687, or 5·3 per cent., non-perforating wounds. This makes a total of nearly 7 per cent. of all cases. As to primary treatment Professor Haab is a great adversary of wet appliances of any kind, whether moistened with plain water, Goulard water, or weak sublimate solution, as the fingers applying them are rarely properly disinfected and in the case of perforating wounds pressure of any kind is very detrimental. The best primary bandage consists of a pad of aseptic wadding with or without a piece of iodoform gauze. It is only in the case of damage done by an alkaline solution or by lime that immediate flushing of the eye with a watery solution is desirable. Even very severe cases, if treated with a pad of aseptic wadding and immediately sent to the hospital, recover well, as was shown in the case of eight school children who were lately severe sufferers from an acetylene explosion at Diessenhofen. Three-fourths of the foreign bodies in the eye can be removed by the use of the great magnet which Professor Haab had constructed and with which he has successfully performed 150 operations. Fragments of copper, deeply seated, are very difficult to remove even for a most experienced operator. Demarre's pince capulaire was useful in some cases where the foreign body was lodged in the corpus vitreum. Professor Haab, practically aided by his assistant, Dr. Sidler, has lately made successful use of tiny iodoform gelatin rods (*kleine Stäbchen*) to disinfect infected wounds; a certain number of 30 cases thus treated gave unexpectedly good results. The iodoform is first treated with a 5 per cent. carbolic acid solution, filtered, dried, and formed into small rods by means of a proper admixture of gelatin.

Zürich, March 9th.

Medical News.

VACCINATION IN BRISTOL.—The vaccination officer's returns relative to children whose births were registered in Bristol from January to June, 1900, have been recently issued. They show that 4651 births were registered; of these children 2451 were successfully vaccinated, eight were insusceptible, and 426 died unvaccinated; 95 certificates of conscientious objections were issued, 180 vaccinations were medically postponed, and there were 463 removals. During 1899 and 1900 the total number of successful vaccinations amounted to 5073 and 5930 respectively.

BRISTOL GENERAL HOSPITAL.—The annual meeting of the governors of this institution was held on March 11th, under the presidency of the Lord Mayor. The medical report showed that the out-patients numbered 31,441, being 131 in excess of any preceding year. The in-patients numbered 2187, an increase of 87 compared with 1899. The daily number of in-patients was 162. 402 patients had been sent to the Jubilee Convalescent Home. The financial statement showed that the total ordinary revenue amounted to £10,586, or less by £1505 than in 1899. The report alluded to the new out-patients' department, with porter's lodge, which is now being erected at a cost of £7000. These alterations will provide new casualty rooms and better waiting-rooms for the out-patients. The electric light is being installed and a new hot water-supply has just been introduced. The total cost of all these much needed improvements is £9000, for which sum the committee confidently appeal to the public.

OVERCROWDING AT STOCKPORT WORKHOUSE.—A report from the medical officer, read at the meeting of the Stockport Board of Guardians on Feb. 25th, reveals what is called in a newspaper report a "difficulty in consequence of the disgraceful overcrowding of the workhouse hospital." There has been a serious outbreak of influenza in the workhouse, "14 deaths in one week being attributed to the disease," and it was in consequence of the overcrowding impossible to isolate the sufferers. Patients have had to be discharged to the body of the house before they were fit "to sleep there or to be classified with the able-bodied." The medical officer says that he is obliged to act contrary to his judgment and that he cannot hold himself responsible if anything untoward should result. Various steps have been taken to meet the emergency. "Even the lock ward was filled with persons who ought not to have been put in such a place, and

the matron was very distressed that she had no option but to put decent people there." This state of things seems more like a reminiscence of the days of Mr. Bumble and Oliver Twist than a picture of what can be met with to-day, and so it seemed to be felt by most of the guardians, one of whom, however, contended that there was space enough and to spare.

PRESENTATION TO A MEDICAL MAN.—On March 6th the members of the Whitefield district of the St. John Ambulance Association presented Mr. A. J. Young, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., with six volumes of Darwin's works as a mark of appreciation of his services as instructor.

PREVENTION OF CONSUMPTION.—A meeting was held at Tavistock on March 7th in support of the proposed sanatorium for consumptive patients in Devon and Cornwall. Mr. C. C. Brodrick, medical officer of health, presided, and Mr. J. W. Spear, M.P., Dr. F. G. Bushnell, and others gave addresses.—A meeting of the Gloucestershire, Somerset, and Wilts branch of the Society for the Prevention of Consumption and other Forms of Tuberculosis was held at the Guildhall, Bath, on March 6th, under the presidency of the mayor, and among those present were Dr. R. Shingleton Smith and Dr. E. Long Fox. Sir James Crichton Browne was the principal speaker. A resolution pledging the meeting to do all in its power to raise funds for the proposed sanatorium was carried. Dr. L. A. Weatherly stated that the proposed building would contain 60 beds. On the motion of Sir J. Dickson-Poynder, M.P., a hearty vote of thanks was passed to Sir J. Crichton Browne.

VACCINATION IN LEICESTER FROM 1873 TO 1900.—*Apropos* the action of the Government in regard to vaccination, or rather non-vaccination, in the borough of Leicester the following official statistics, presented at a recent meeting of the Leicester Board of Guardians, make interesting reading:—

Year.	Births registered.	Successfully vaccinated born during the year.	Vaccinated by public vaccinators.	Total successfully vaccinated during the year irrespective of date of birth.	Cost. £ s. d.
1873	4446	3730	2266	3692	353 7 7
1874	4365	3590	2700	2764	363 1 0
1875	4256	3400	2115	3527	336 12 7
1876	4773	3650	2188	3426	347 17 11
1877	4749	3509	2318	3653	347 0 7½
1878	4777	3260	2106	3372	344 12 0
1879	4695	3086	2036	3146	331 5 0
1880	4860	3010	1904	2886	333 15 1
1881	4712	2948	2172	3417	428 5 0
1882	4855	2660	1807	3106	367 14 3
1883	4819	1732	1300	1968	321 0 7

HEALTH OF TAUNTON.—Dr. H. J. Alford, the medical officer of health of the urban and rural districts of Taunton, has just issued his annual reports. He states that 427 deaths occurred in the borough, equal to a rate of 19·2 per 1000. The births were 535, or at the rate of 26·2 per 1000. There were 42 deaths from zymotic diseases, 28 being due to measles. In the rural district there were 283 deaths, equal to a rate of 16·6 per 1000. 382 births were registered—a rate of 21·8 per 1000. During the year 66 patients were admitted to the isolation hospital; only two of the cases were fatal, both patients dying from diphtheria.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. C. J. Rossander, Professor of Ophthalmology in the University of Stockholm.—Dr. Manassein of St. Petersburg, one of the most eminent physicians in Russia. He was born in Kazan in 1841 and after studying medicine in Moscow and Dorpat travelled abroad to various foreign universities. At Tübingen he worked under Professor Hoppe-Seyler and was entrusted by him with the charge of the "castle laboratory." On his return to Russia he became assistant to Professor Botkin, and in 1876 was appointed clinical professor. His chief work lay in experimental pathology. For many years he was editor of the chief Russian medical weekly, the *Vrach*.

METROPOLITAN ASYLUMS BOARD.—At the last meeting of the Metropolitan Asylums Board the Asylums Committee reported that they had received with regret a letter from Mr. G. S. Elliot intimating that in consequence of ill-health he felt compelled to relinquish his office of medical superintendent of Caterham Asylum, which office he had held for upwards of 21 years. At their next meeting the committee stated that they intended to consider the steps to be taken to appoint a successor to Mr. Elliot who desires to vacate his office on June 30th next. In the meantime they recommended that the terms upon which the appointment of a medical superintendent for the Caterham Asylum in succession to Mr. Elliot should be made as follows: salary £600 per annum, rising annually to a maximum of £800. Other emoluments: unfurnished house, coals, gas, and washing. The report was adopted. The chairman of the Finance Committee in his annual statement with regard to the expenditure of the board stated that the total population for which they were responsible on Sept. 30th, 1899, was 15,481; of this number 4117 were the staff and 11,364 patients. The figures for the year 1900 were 14,193, of which 4145 were staff, and 10,048 patients—a decrease of patients by 1316 and an increase of 28 in the staff in attendance. The Local Government Board wrote confirming the appointment of Dr. T. Colcott Fox as dermatologist of the Bridge School for Children.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Cremation.

PROGRESS is being made in the House of Lords with a Bill on the subject of cremation. The measure gives a general power to burial authorities to make provision for the burning of human remains, while requiring that the plans of all crematoria shall be approved by the Local Government Board, and it lays upon the Home Secretary the duty of making regulations as to the conduct of crematoria. One of the clauses provides against interference with the jurisdiction of coroners and says that nothing in the Act shall authorise the burial authority to create or permit a nuisance.

Proposed Exemption of Hospitals from Local Rates.

The Bill to secure the exemption of hospitals from local rates was set down for second reading in the House of Commons on Wednesday, March 13th, but it was not reached until the expiry of the time for the discussion of contested business and consequently no progress was made with it.

HOUSE OF COMMONS.

THURSDAY, MARCH 7TH.

The Fees of Medical Witnesses.

Mr. LAWRENCE asked whether he would explain on what grounds medical witnesses in England and Wales were allowed only one guinea per diem, while in Scotland they were paid two guineas with a further

sum added for each case, and in Ireland the fee of one guinea only required an attendance in court of three hours in the town of residence and was changed to two guineas with travelling allowance in the case of other towns; and whether he would authorise an inquiry into the matter with a view to remedy the inequality of remuneration referred to.—Mr. RITCHIE: I do not think the fees of medical witnesses can be touched without dealing at the same time with those of other witnesses, and this I am not prepared to do in view of the largely increased cost of prosecutions which might be the result of such a revision of the present scale.

Vaccination Prosecutions.

Sir MANCHERJEE BHOWNAGGREE asked the Home Secretary if he would state how many prosecutions had been instituted by the vaccination officer of the borough of Bethnal Green since the passing of the Vaccination Act, 1898; how many convictions were obtained, and how many of the fines imposed remained unrecovered; whether he was aware that most of the persons prosecuted were unable to defend themselves effectually owing to ignorance of the procedure provided under Section 2 of the aforementioned Act; and, if so, was he prepared to allow a remission of the fines imposed.—Mr. RITCHIE: It would be impossible to give the information asked for in the first three queries without a search of the police-court records or without reference to the guardians, and the work of obtaining the information would involve much time and labour. I have no reason to suppose that persons prosecuted under the Vaccination Acts in Bethnal Green have found any greater difficulty in defending themselves than persons similarly prosecuted in other places, but if the hon. member will furnish me with full details of any case in which he thinks the defendant has suffered injustice I will inquire into it.—Sir MANCHERJEE BHOWNAGGREE asked the President of the Local Government Board whether he was aware that vaccination prosecutions in Bethnal Green and adjacent boroughs were being rigorously pursued against persons who had a conscientious objection to vaccination and had resulted in convictions owing to the difficulty encountered by the accused persons of proving that their objection was based on a conscientious belief; and seeing that in this respect and owing to loss of time and wages which was occasioned by the process of asserting their objection under Section 2 of the Vaccination Act, 1898, that Act did not give full relief to objectors, whether he purposed adopting any steps by which the operation of that Act might be rendered more easy and effective in future.—Mr. WALTER LONG: I am not myself aware of difficulties of the kind referred to in the first paragraph of the question and I should regret if any such difficulties were experienced. The answer to the second part of the question must, however, be in the negative.

FRIDAY, MARCH 8TH.

St. John Ambulance Brigade in South Africa.

Sir FREDERICK MILNER asked the Secretary of State for War whether it had been officially decided that members of the St. John Ambulance Brigade who had served in South Africa were not entitled to the war gratuity that was by a recent Order awarded to all classes of troops engaged in the war; and whether, seeing that the members of the St. John Ambulance Brigade had been working with the Royal Army Medical Corps, doing the same duties and bearing the same risks and hardships, and also seeing that 50 out of the 1900 members of the St. John Ambulance Brigade serving in South Africa had died in the execution of their duty, he would reconsider this decision.—Mr. BRODRICK: The answer to the first paragraph of the question is in the affirmative. The war gratuity is a military gratuity originally intended as a substitute for prize-money and is not applicable to civilians employed on specific terms during the war. I may remind the hon. member that members of the St. John Ambulance Brigade are paid at considerably higher rates than the corresponding ranks of the Royal Army Medical Corps.

MONDAY, MARCH 11TH.

Dangerous Tea.

Mr. HENRY HOBHOUSE asked the Secretary to the Treasury if his attention had been drawn to the fact that quantities of inferior Ceylon and other teas alleged to contain microbial products dangerous to health were being sold in bond in London at prices ranging below 4*d.* per pound; if the Customs officers had taken and analysed any samples of such teas, and with what results; and what amount had been seized and destroyed during the last 12 months; and, if in the interests of public health he was willing to consent to an inquiry into the best methods of checking the sale of such unwholesome teas by determining some minimum standard of purity and by securing a proper analysis of such teas before they were blended with other teas.—Mr. AUSTEN CHAMBERLAIN replied that the Board of Customs had no knowledge of sales in bond of tea containing microbial products dangerous to health. They had power to forbid the introduction of tea that was found on analysis "to be mixed with other substances or exhausted tea" or was declared by the analyst to be "unfit for human food." During the last 12 months 2055 packages were refused admission for home consumption or for use as ship stores. The second paragraph of the question should be addressed to the Local Government Board, which was the authority specially charged by statute with the protection of the public health.

Vaccination in England and Wales.

Mr. WALTER LONG, answering a question addressed to him by Mr. BARTLEY, said that the latest complete returns with regard to the vaccination of children in England and Wales were those for 1893. They showed that the number of children born in the year was 923,059, and of these 562,737 were successfully vaccinated.

The Government and the Pure Beer Question.

Mr. ALFRED DAVIES asked the President of the Local Government Board if his attention had been called to the unanimous resolution passed by the Carmarthenshire Chamber of Agriculture as to the necessity of a Bill being passed to secure purity in beer by laying down therein the ingredients of which beer might be composed and the compelling of brewers at regular intervals to make a return of beer brewed and ingredients used; and, if so, whether he could assure the House of his intention to introduce promptly a Bill carrying out the purport of this resolution.—The CHANCELLOR of the EXCHEQUER: The President of the Local Government Board has asked me to answer this question, as the resolution aims not only at the exclusion of deleterious ingredients from beer, but at limiting the freedom of brewers to use materials which, though wholesome, are not malt or hops. I can give no such assurance on behalf of the Government as is desired by the hon. member.

The Insanitary Condition of the Central Criminal Court.

Mr. J. R. DEWAR and Dr. FARQUHARSON addressed questions to the Under Secretary of State for Home Affairs with reference to the insanitary condition of the Central Criminal Court and the indisposition of certain of the judges who had presided in the court.—Mr. JESSE COLLINGS, in reply, said that the City of London authorities were responsible for the building in which the Central Criminal Court was held. In order to furnish them with a site on which to build a new court the Government had agreed to surrender Newgate Prison, but in order to make this possible extensive alterations had to be made in prison buildings elsewhere. This involved considerable delay, but it was not the case that the Government were placing difficulties in the way. As a matter of fact, the Prison Commissioners were doing all they could to complete the arrangements which were a necessary preliminary to the discontinuance of Newgate Prison and the transfer of the site to the City of London Corporation.

TUESDAY, MARCH 12TH.

Nursing in Irish Workhouses.

Mr. GEORGE WYNDHAM, Chief Secretary for Ireland, made a statement on this subject by way of answer to a question addressed to him. He said that in the interests of the sick poor it was imperatively necessary that the assistant nurse of a small workhouse hospital should be an experienced qualified nurse, as she had entire charge of the sick during the temporary absence of the nurse from any cause, besides having probably to take charge of patients at night in many cases. The opinion of the Local Government Board in Ireland was that no person should be appointed and paid for discharging the duties of a nurse unless she had been sufficiently trained. The Board did not ask that an assistant nurse should be fully trained within the meaning of Section 58 of the Local Government (Ireland) Act, 1898, and the Board had always been glad to encourage boards of guardians to train nurses whenever a systematic course of training had been proposed under sufficient and competent teachers as had been done in some unions. The Board was, however, unable to approve of proposals that inexperienced untrained girls should be permitted to discharge nursing duties and to acquire the status of a nurse without any sufficient or systematic instruction.

ROYAL COMMISSION ON ARSENICAL POISONING.

WEDNESDAY, MARCH 6TH.

THE Royal Commission on Arsenical Poisoning held a meeting on March 6th in one of the rooms of the Westminster Palace Hotel. Lord KELVIN presided and the other Commissioners present were Sir W. S. Church, Sir William Hart Dyke, M.P., Professor Thorpe, Dr. B. A. Whitelegge, and Mr. H. Cosmo Bonsor, with Dr. G. S. Buchanan, secretary to the Commission.

Evidence of Dr. E. W. Hope.

Dr. EDWARD WILLIAM HOPE, professor of public health in the Victoria University and medical officer of health of the City and Port of Liverpool, examined by the CHAIRMAN, said that he had considered the amount of recent exceptional sickness and death attributable to poisoning by arsenic, and he was one of the members of a small subcommittee appointed on Dec. 20th by the Liverpool Medical Institution to inquire into the matter. About 100 cases of poisoning by arsenic which admitted of easy verification were tabulated by this sub-committee. These cases were treated in public institutions and eight of them were fatal, inquests being held in four instances. Besides these definite cases of poisoning and maiming there were many others in which the symptoms were less marked and the verification less easy. Many of these cases occurred in private practice, but some of them in public institutions. The exceptional sickness and death appeared to have been entirely owing to arsenic in beer. Samples of chocolate, syrups, jams, marmalade, and preserved sweets of all kinds were systematically examined; 107 samples carefully and specifically examined during November, December, and January did not contain any trace of arsenic. For many years it had been a routine practice in Liverpool to take samples of all kinds under the Sale of Food and Drugs Acts, special attention being directed to suspected articles. Until recent occurrences the samples of beer taken for analysis had been very few. In October last, however, eight samples of beer and two samples of stout were purchased and reported to be genuine. Some time prior to this Dr. Nathan Raw mentioned to him the increasing number of patients coming under his care at Mill-road Infirmary suffering from what he regarded as alcoholic neuritis. Towards the end of November the announcement was made in the Manchester newspapers that Dr. E. S. Reynolds had cases of arsenical poisoning under his care at Manchester and that Mr. C. H. Tattersall had reported that arsenic had been found in beer purchased in the city. The cases at Mill-road Infirmary already alluded to were at once recognised in the light of this information as cases of arsenical poisoning. As the patients at Mill-road Infirmary were all beer-drinkers there was *prima facie* evidence that their illness was caused, as in Manchester, by the consumption of beer. At that time (Nov. 26th) there was no positive evidence of this in his possession nor was there any evidence as to the source of the arsenic.

Have you any reason to believe that detrimental effects from arsenic

in beer have occurred previous to this outbreak?—It appears so, though there are no analytical reports to support that belief. It is by inference I say there was arsenic in beer some months prior to the 26th November, when it was definitely ascertained to be there.

Peripheral neuritis and alcoholic neuritis were known before this outbreak?—Yes; we are very familiar with alcoholic neuritis in Liverpool.

Do you think that in some cases prior to 1900 the illness may have been really due to arsenic and not merely to alcoholic neuritis?—It is possible that it may have been, but we have no evidence to show that it was the case.

Do you know anything of beer having been suspected and tested for arsenic before the present outbreak?—The practice of the health authorities has been to have beer analysed, but we have never had any report from the analysts to show that there was arsenic in beer until November of last year.

Was the analysis prior to last year of such a character that arsenic would be detected by it?—That I am not in a position to say. The samples were said to be genuine samples and I cannot think that a sample would be certified to be genuine if it contained a deadly poison such as arsenic.

In further examination by the CHAIRMAN Dr. HOPE said that the gravity of the situation was increased by the fact that the consumption of alcohol in its various forms in Liverpool was excessive and in certain areas of the city exerted a material influence upon the public health. According to the verdicts of the coroners' juries many scores of people lost their lives annually from excessive drinking. The consumption of beer in Liverpool approximated to something like three-quarters of a million gallons per week. It was an enormous consumption, but he had no reason to doubt the figure he had given. There were 2223 houses within the city where beer was sold. It was obvious, therefore, that if an article so extensively used was actually at that moment the medium for poisoning by arsenic only the promptest measures could avert a catastrophe. The provisions of the Sale of Food and Drugs Acts did not admit of a sufficiently speedy application to meet the emergency and seizure of the contaminated beer under the Public Health Act so soon as evidence of contamination was available commended itself to him. The inspectors, three in number, under the Sale of Food and Drugs Acts were instructed to procure samples of beer for analysis, but having regard to the utter impossibility of obtaining reports upon samples under these Acts within a period of time which would be of use he requested the analysts to employ the most rapid processes to enable them to determine whether or not arsenic was in the samples, irrespective of the quantity present. The first and obvious duty was to protect the public health by ridding the city of the arsenical beer. At the same time samples were taken with the formalities of the Sale of Food and Drugs Acts to be subsequently dealt with so that proceedings could be taken if it were thought expedient. Samples were taken from 60 different firms. Arsenic or traces of arsenic to a varying extent were found in the beer supplied by 20 of these firms. Out of 237 samples taken from these 20 firms 52 were found to contain arsenic. From the remaining 40 firms 178 samples were taken and all of them were entirely free from contamination. Many of the brewing firms had themselves employed analysts and had anticipated action by destroying the beer. In these ways the brews implicated were speedily detected and large quantities of contaminated or suspected beer were poured into the sewers. There did not appear to have been any neglect or delay in the destruction of the arsenicated beer excepting in two cases, in one of which it appeared that the beer had still been retained upon the premises with a view to recover its value, an objectionable and most improper proceeding. The total quantity of the beer destroyed was 267 000 gallons. Had they proceeded under the Sale of Food and Drugs Acts he calculated that there would have been a delay of between three and four weeks in getting rid of the beer. It must not be overlooked that at the end of November and the beginning of December all the chemical laboratories (not only those of the public analysts) were overwhelmed with samples of beer, the brewers themselves sending large numbers of samples. So far as the city analysts were concerned it would not have been possible for them to have examined one-tenth of the number of samples for a quantitative analysis which were dealt with in the manner described. The source of the arsenic was speedily traced. It very soon became evident that brewers who had been using glucose manufactured by Messrs. Bostock and Company, Limited (a firm of manufacturers in Garston, a few miles from Liverpool), were those whose beer contained arsenic; beer manufactured by those who had not used Bostock's sugar was free from arsenic. It transpired that brewing firms whose beer was not found to contain arsenic were customers of Bostock's but it was stated that they did not use Bostock's sugar. On Nov. 26th a circular was issued by Messrs. Bostock asking their customers to suspend the use of the glucose pending further investigations, and on Nov. 30th they sent a further circular asking for the return of sugars which their customers held. The source of the arsenic was subsequently shown to have been sulphuric acid supplied by Messrs. Nicholson and Sons of Leeds, in circumstances which no doubt had come before the Commission. Whilst glucose made from this poisonous sulphuric acid was by far the most important source of the arsenic in beer, arsenic in small quantity and derived from the coke or coal used in the kiln was found in malt, and traces of it were found in the beer made from this malt. The quantity, however, was unimportant in comparison with that in the glucose. The quantity in the glucose was estimated by the analysts to be 4½ grains to the pound in one sample and 9½th grains to the pound in another sample. The first sample would, the analysts estimated, represent from one-third of a grain to one grain of arsenic per gallon of beer, and the second presumably more than double those amounts. It had been stated in view of minute traces of arsenic being found in malt and elsewhere that a minimum permissible quantity of arsenic should be legalised. It would be well to remember, however, that even assuming that one-fiftieth or one-hundredth part of a grain in a gallon would do no immediate harm, yet fortunately it was the exception to find any arsenic present, and there was no necessity therefore that there should be any, and he believed that it would be a fatal mistake in more senses than one to permit the presence of any amount, however small, of so poisonous a material as arsenic. It, therefore, was well established that exceptional sickness and death had been due in Liverpool to arsenic in beer, but no arsenic had been found in any other article of food or drink whatever. It was also shown that the arsenic did find its way into the beer by means of glucose, in the preparation of which sulphuric acid containing arsenic was used, and it also appeared that in the process of drying malt might become contaminated with arsenic in minute quantities. The inference was, therefore, that the fewer articles used in the manufacture of beer the better, since each one might possibly become contaminated. In any case there could be no objection to the brewers making known in the public interests the materials from which their beer was manufactured, a knowledge which would give the public the option of selecting beer made from ingredients which they might consider the most wholesome and least liable to contamination. The following facts were plain, viz.:—

1. That a poisonous arsenical acid was supplied in the manufacture of a material used in making beer.

2. That that acid, which in any case might be suspected, was received and used in the manufacture of glucose without being tested or examined in any way for arsenic.

3. That that glucose in its turn was used by brewers for the manufacture of beer without examination of any kind for arsenic, and the beer so distributed was the cause of illness, maiming, and death.

Hence it was imperative that a strict supervision should be exercised over all the material used in the manufacture of beer.

Brewers supplying either retailers, licensees, or managers of public-houses with beer, should send with the beer a warranty showing the materials employed in its manufacture and guaranteeing the purity of each.

Evidence of Mr. A. G. Salamon.

Mr. ALFRED GORDON SALAMON, a Vice-President of the Society of Chemical Industry and member of the Council of the Institute of Chemistry, was the next witness to give evidence. He explained that he had had 17 years' practical experience of the technology of brewing and had been largely employed by the brewers throughout the country to advise them as to the best materials to employ for arriving at satisfactory fermentation. On Nov. 17th he received a letter from Mr. James G. Groves, M.P., of Messrs. Groves and Whitnall, Limited, Regent-road Brewery, Salford, saying that he had sent on samples of his own and other local beers for analysis in order to test the type of alcohol present in them. In a letter received on Nov. 20th Mr. Groves said he wished to know whether any of the samples showed traces of an irritant poisoning such as lead or arsenic. After receiving this letter he and another witness proceeded to test for arsenic and found that several of the samples contained it, not only in traces, but in notable quantities. Witness then described in detail the action taken by himself and other experts at the instance of the Manchester Brewers' Association. Having done so he said that on Nov. 29th he received from Mr. C. H. Tattersall 15 samples of raw materials which were being employed by Messrs. Bostock at the time of Mr. Tattersall's visit in the manufacture of glucose and invert sugar and also of the finished products as they were being sent to the brewers. Careful analysis of these samples gave the following results: sulphurous acid free from arsenic, sago flower free from arsenic, tapioca flower free from arsenic, whiting free from arsenic, cane sugar free from arsenic, glucose grossly contaminated with arsenic, invert sugar grossly contaminated with arsenic, four more samples of glucose grossly contaminated with arsenic, invert sugar grossly contaminated with arsenic, maize meal free from arsenic, glucose grossly contaminated, and sulphuric acid very dangerously loaded with arsenic. He had made a quantitative estimation of the arsenic in these samples and as a result he had no hesitation in saying that having regard to the statement of the medical authorities as to the quantities necessary to produce a toxic effect the brewing sugars when used in normal quantity in the production of beer would be dangerously poisonous. In the opinion of witness the employment of the poisonous sulphuric acid fully accounted for the results disclosed. He found to his surprise that in no single case was Bostock's sugar alone employed. It would appear to be the custom in Manchester to employ two and sometimes three different makes of brewing sugar, both glucose and invert sugar, and that sometimes in the same brew. But for this custom the amount of poisonous beer brewed during the epidemic would have been far greater in certain breweries even than had been the case. The custom permitted witness to compare the price paid for Bostock's sugar with that paid to other makers, and he was in a position positively to assert, after examination of hundreds of invoices which were freely placed at his disposal by the Manchester brewers, that the Bostock sugar was not in any way cheaper nor were the conditions of payment more favourable to the brewer than that of the other and best makes upon the market. An inspection of the various sugars, both glucose and invert, made it impossible to distinguish the different makes, and those of Messrs. Bostock were of extremely good appearance. Indeed, no suspicion could attach to the appearance of the Bostock sugars. Witness was in a position to assert that the arsenical contamination of beers in poisonous quantities in Manchester and its district was absolutely at an end, and the result of his investigations proved without any doubt whatever that it was solely occasioned by the use of Bostock's sugars. In the course of the inquiry of the commission of experts the presence of traces of arsenic in malt and other brewing materials had become manifest. This commission found it necessary to fully investigate this question of traces, which was distinct from that of poisonous contamination; the work involved had been very great and was not yet complete, and, therefore, witness asked that his evidence on this point might be deferred. In the course of cross-examination Mr. Salamon said that there was no difficulty in ridding malt of all arsenic. When asked by Sir William Church whether he had formed any opinion as to what should be considered a negligible quantity of arsenic in beer he replied that he should rather say "none at all." It was quite feasible for the brewer to brew beer which contained no arsenic whatever, and as a matter of fact the bulk of the beer made in England did not contain a trace of arsenic.

The Commission then adjourned.

THURSDAY, MARCH 7TH.

There was another meeting of the Commission on March 7th, at the same place, Lord KELVIN again presiding.

Mr. Salamon further Examined.

Mr. SALAMON presented himself for further examination, and in reply to Professor THORPE said that his inquiries had not gone far enough to enable him to form an opinion on the point whether there was any connexion between neuritis and the higher alcohols. He had been associated with the analysis of beer for many years, and until this outbreak he had never tested samples of beer for arsenic simply because the idea had never occurred to him. He had looked for selenium in materials sent to him, but he was not yet in a position to give evidence on the subject. He had not completed a quantitative determination. As far as he had gone he had only been able to determine the presence of minute traces in certain substances, but he would not even like to say to-day that it was selenium. He had not gone sufficiently far to speak with any certainty on the subject. He might say that at present he had not found selenium in beer.

In reply to the CHAIRMAN Mr. SALAMON gave the opinion that the risk of arsenic in malt could be avoided by abstinence from the use of gas coke in the process of kilning and by employment of anthracite.

Evidence of Mr. J. G. Groves.

Mr. JAMES G. GROVES, M.P., chairman and managing director of Messrs. Groves and Whitnall, brewers at Salford and Manchester, examined by the CHAIRMAN, said that the scope of their business was principally confined to Manchester and Salford and their output was considerably the largest in these two towns. Until November last he had no reason whatever to doubt the purity of their beers. On the 12th of that month Mr. R. D. Cran, one of the district medical officers of Salford, called upon him with reference to the amount of sickness in his district. Mr. Cran described the sickness as alcoholic neuritis and said it was "alarming and there were many deaths traceable to it"; he considered that the illness was principally localised amongst the drinkers of beer and his theory was that it was due to some of the higher alcohols. Witness suggested that this was more indicative of spirit- than beer-drinking, but Mr. Cran replied that the evidence very strongly pointed to beer-drinkers and not spirit-drinkers, although the mischief might be assisted by the consumption of spirits. On the 24th he called upon Dr. Miller, Ph.D., F.I.C., F.C.S., and engaged him to examine all their beers in stock as well as brewing materials and all brews before delivery. From that moment they did not send out any beer which had not been analysed and certified by Dr. Miller. They took every precaution to stop the sale of the beer in the hands of their customers until they had been able to have samples of it analysed. The beer in customers' hands of all brews that were not certified free from arsenic they either turned into the sewers or brought back to the brewery to be destroyed. Altogether the contents of many thousands of barrels were destroyed, the value of the beer and stout thus dealt with being not less than £15,000. They also took every precaution with regard to having the brewery plant thoroughly purified and examined to see that there was no remaining contamination. Mr. Salamon had examined their plant and taken shavings from the insides of their casks, which after analysis he reported to be free from any trace of arsenic. Since Nov. 26th a copy certificate of purity had been attached to each barrel of beer and stout sent out from their breweries. It was in these terms: "I certify the purity of the brew of beer from which this cask is filled," and was signed by Dr. Miller. The form was submitted to the special sub-committee of the Manchester Brewers' Central Association who approved it and recommended it for general adoption. He might say that Bostock's was the only sugar in which they had discovered arsenic. For some time previous to August, 1900, they had not used Bostock's glucose, but that of other manufacturers. The firm with whom they were then dealing being very busy asked them to suspend their orders and they did so to oblige them, and in consequence they commenced again to use Bostock's glucose. Bostock's invert was only used for priming. Since discarding Bostock's sugar they had required certificates of purity to be furnished to them of all materials used in brewing and they had conducted careful and minute analyses themselves. Early in December, Mr. Estcourt, the public analyst for Manchester, publicly reported traces of arsenic in malt; this caused his firm to submit samples to him and to Dr. Miller and from that time they had discarded doubtful samples and brewed only from those certified safe. They had found that malts cured with ordinary gas coke were generally contaminated and those with anthracite coal were free or practically so. Brushing and polishing the malt made a great improvement and was in his opinion a necessary safeguard. They required this to be done with all their malts and they insisted on a guarantee of purity from the malsters with each consignment. So far as sugar was concerned, his opinion was that the danger in their beers ceased absolutely on Nov. 23rd with the discontinuance of the Messrs Bostock's materials. During 1900 the consumption of Bostock's glucose as compared with the other glucoses used was 8 per cent. of the total, and almost the whole of that consumption took place during the two and three months between August and November. The amount of invert used for priming was between one and a half and two pounds per barrel.

By Sir WILLIAM HART DYKE: So far as his knowledge went he should say without hesitation that the exceptional sickness and death had been due entirely to the use of Bostock's sugars. He should say that the small traces of arsenic found in malt would not be detrimental to the public health. His firm got associated with this arsenic scare at a very early stage and the public at the first jumped to the conclusion that theirs was the only beer contaminated. It took a long time to eradicate a misconception of this kind and in this way his firm had suffered much more than they deserved. The inquiries that had taken place had opened the eyes of the scientific world to facts not previously recognised, and his firm and the brewing trade generally were alive to the lessons to be learned and he hoped were profiting by them. He believed that the brewers in their own interest would take such precautions as would prevent the possibility of such a misfortune recurring, even if Parliament took no action. What had taken place had created a new situation and in the future no brewer would be able to shelter himself under the excuse of carelessness, or want of knowledge.

By Sir WILLIAM CHURCH: Before Mr. Cran called upon him he had seen Dr. Forsyth the club doctor, who had pointed out that more than the average number of the brewery employés were "off" with a form of influenza, but it did not occur to witness that the illness was due to anything in the beer. The employés were allowed three pints of light beer per day, but of course the outside men who delivered the beer to customers would drink more than that quantity in the course of a day, for it was the habit of customers to treat them. His firm had experienced no difficulty in getting certificates of purity from the sugar-makers. The maltsters were somewhat alarmed at first and some of them hesitated, but the firm insisted on the certificates as a condition of custom and they got them. The guarantee was that the material should be free from contamination by arsenic or other deleterious substance.

By Professor THORPE: The certificate of purity issued by Dr. Miller was a warranty to the firm and they passed it on to the customer, not with the idea of getting rid of any responsibility in the matter, but of assuring the customer that the firm had got the best expert assistance.

On the conclusion of his evidence Mr. Groves was congratulated by the CHAIRMAN on the promptness and thoroughness of the action he had taken and on its success.

Evidence of Mr. E. W. T. Jones.

Mr. E. W. T. JONES, F.I.C., public analyst for the county of Stafford and the boroughs of Wolverhampton, Walsall, Kidderminster, and Newcastle-under-Lyne, was next examined. In the course of his evidence he said that since the beginning of December last he had tested about 300 samples of beer, representing about 100 brewers, including about 30 home brewers. 26 samples were arsenical to the extent of from one-sixtieth to just over half a grain per gallon, calculated as arsenious oxide. 33 samples contained arsenic computed to be well under one-twentieth of a grain per gallon. Of these, 15 were from one brewer who had discontinued the use of Bostock's glucose, and in this case the arsenic found had now been proved to be due to arsenical malt. The cause of the slight amount of arsenic in the other 18 samples he had had no means of investigating, but he believed Bostock sugar had been used by all these brewers. None of the home-brewed beers were arsenical. He had tested 13 samples of malts, eight of which were from one maltster. Three were decidedly arsenical, containing from one-fortieth to one-fiftieth of a grain of arsenious oxide per pound. The remaining five were slightly arsenical, containing apparently less than one-one-hundredth of a grain per pound. Five other samples from three maltsters were free from arsenic. He had found malt made with a certain fuel decidedly arsenical. This fuel was a certain Yorkshire gas coke. He had no analytical experience as to the fuel itself. He had not examined any of the coals and coke in that district for arsenic, but he concluded indirectly that they were not arsenical to any important extent, as he had found no malt arsenical which had been made in that district. He had not had any arsenical beer into the composition of which Bostock sugar had not entered, except in one instance, and that was where the malt was prepared from Yorkshire gas coke. He had tested 22 brewing sugars, representing about eight different makes, and in no case had he detected arsenic except in Bostock's sugar, of which he had had two samples. One contained 0·023 per cent., and the other 0·021 per cent. of arsenious oxide, say, one-tenth of a grain per ounce. A sample of Bostock glucose sent to him privately contained 0·05 per cent. of arsenious oxide. He had tested two samples of cane sugar as used in brewing and both were free from arsenic. 25 samples of treacle and golden syrup were tested, all of which were found free from arsenic. Some were adulterated with starch glucose syrup. He tested 17 samples of jams, marmalade, and mincemeat, and found them all free from arsenic. 27 samples of confectionery were tested, and all were found free from arsenic. He tested two samples of bisulphide of lime, one of sulphurous acid, and one of finings; all were free from arsenic. His method for testing arsenic in beer was practically the same as that recommended by the experts of the Manchester Brewers' Association. He had satisfied himself that by this test he should not pass beer containing more than one-twentieth of a grain per gallon and possibly should exclude beer containing a smaller quantity than one-twentieth.

In reply to Sir WILLIAM CHURCH witness said that when beer was submitted to him under the provisions of the Sale of Food and Drugs Acts he had looked for salt and sulphuric acid but not for arsenic, but when the Chairman questioned him as to the desirability of legislation directed against poison as well as mere adulteration Mr. Jones expressed the view that the field would be too wide for such legislation.

The Commission adjourned until Wednesday, March 13th.

Births, Marriages, and Deaths.

BIRTHS.

BROWN.—On March 1st, at Museum-street, Ipswich, the wife of H. H. Brown, M.D., F.R.C.S., of a son.

EDWARDS.—On March 5th, at Halling, Rochester, the wife of Arthur Spencer Edwards, M.B., C.M. Edin., of a son.

MICHELS.—On March 10th, at Finsbury-square, E.C., the wife of E. Michels, M.D., F.R.C.S., of a son.

MURISON.—On March 5th, at Pier-road, Erith, Kent, the wife of W. R. Murison, L.R.C.P. & S. Edin., of a son.

WADE.—On March 6th, at Royal-terrace, Southend-on-Sea, the wife of Charles H. Wade, M.A. Oxon., L.R.C.P., M.R.C.S., of a daughter.

MARRIAGES.

CLARKE—BRYAN.—On March 6th, at Christ Church, Leicester, by the Rev. A. A. Isaacs, M.A., of Bath, assisted by the Rev. T. H. Austin, M.A., vicar of Queniborough, Charles Harold Clarke, M.B., B.S., of Northcote Villa, Uppingham-road, Leicester, third son of the Rev. Charles Clarke, B.A., of Ashby-de-la-Zouch, to Mary Louise, eldest daughter of C. F. Bryan, M.R.C.S., &c., Spa House, Leicester.

GILBERTSON-MCDOUGALL.—On March 9th, at Christ Church, Lancaster-gate, William Gilbertson, M.A., M.D., eldest son of Joseph Gilbertson, Evelyn-gardens, S.W., to Mabel Neal, daughter of Archibald McDougall, Orme-square, Kensington-gardens, W.

POWELL—PEACH.—On the 12th inst., at All Saints, Leavesden, Herts, by the Rev. Wilfrid Robinson, B.A., vicar of Tadcaster, assisted by the Rev. Arthur Wilson, M.A., vicar of the parish, Cecil Powell, M.A., M.B. (Cantab.), Calverton Lodge, Stony Stratford, youngest son of C. Bollard Powell, of Southborough, to Emily, youngest daughter of the late W. H. Peach, Waingroves Hall, Derbyshire.

WALKER—WALKER.—On the 9th inst., at Christ Church, Streatham-hill, Herbert John Walker, M.R.C.S., L.R.C.P., of the Priory, Springfield-road, Brighton, to Ethel Marion Walker, of 8, Telford-avenue, Streatham-hill.

DEATHS.

OTWAY.—On Wednesday, March 13th, at 1, Pepys-road, Raynes Park, near Wimbledon, of pneumonia, Henry Carrol Otway, M.R.C.S., L.R.C.P. Lond., youngest son of the late C. W. C. Otway F.R.C.S. Eng., aged 41 years.

SNOAD.—On March 6th, at Albion House, Aylestone-park, Leicester, Edward Hemings Snoad, M.R.C.S., L.S.A., aged 70 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DISREPUTABLE ADVERTISEMENTS.

IN spite of the publicity given to the trade of "Dr." Davis by recent legal proceedings to which we have referred, and in spite of our having called attention to the nature of "Dr." Davis's Pills, "a Boon to Womankind," the *People* continues to insert the advertisements of "Dr." Davis. The editor, or advertisement editor, if there be such a functionary on the staff of the *People*, also thinks fit to affix the heading "Medical Books" to the following list which appears in the same column as "Dr." Davis's advertisement:—

MEDICAL BOOKS.

ARISTOTLE'S GREAT WORKS, 447 pages, 2*s.*, 465 pages, 2*s.* 6*d.*; coloured plates.—From T. P. Haines, Prospect-terrace, South Tottenham.

ON "NERVOUS DEBILITY" (so called) in MEN. By a SURGEON.—Published by Newnham and Cowell, 75, Chiswell-street, E.C. 1*s.*, post free.

WHAT EVERY WIFE AND MOTHER SHOULD KNOW.—Send 4 stamps to Leslie Martyn, Ltd., Medical Booksellers 34, Dalston-lane, London.

ARISTOTLE'S GREAT WORKS, 2*s.* plain, 2*s.* 6*d.* coloured plates; Wife's Handbook, 7*d.*; list post free.—From P. Harvey, 255, Kingsland-road, London.

THE WIFE'S HANDBOOK, by Dr. H. A. ALLBUTT, D.C.L., LL.D., post free, 7 stamps. Also THE HUSBAND'S HANDBOOK, post free. 8 stamps. Or the Two for 1*s.* 2*d.*, from T. P. REID, Discount Bookseller, West Green-road, London, N.

DR. FOOTE'S PLAIN HOME TALK. 1,248 pages, 400 illustrations, 18 coloured plates, 250 prescriptions; post free 8*s.* 6*d.*; prospectus free.—Leslie Martyn, Ltd., Medical Bookseller, 34, Dalston-lane, London.

Post Free Three Stamps.

A TREATISE on the Cure of Nervous and Physical Exhaustion in Men, Loss of Vital Power, and its accompanying diseases: their successful Cure by an entirely Original and Effective System of Treatment.—JAMES MURRAY, 7, Southampton-row, London, W.C.

We need hardly comment on the above except to point out once more that under the Indecent Advertisement Act of 1889 advertisements "relating to syphilis, gonorrhœa, nervous debility, or other complaint or infirmity arising from, or relating to, sexual intercourse" shall be deemed to be matter of an indecent nature if posted in a public place or in a public urinal, that their publication in a lay newspaper can hardly be claimed to be for the good of its readers, however profitable they may be to its proprietors and that there are many advertisements of this class, other than those we have cited, in the *People*.

"Dr." Davis still advertises in *Reynolds's Newspaper*, another weekly publication which as well as the *People* is read by the class of readers to whom such advertisements as those of "Dr." Davis are likely to appeal. *Reynolds's Newspaper*, however, inserts it in a slightly altered form and it appears as follows:—

FOR NEARLY 20 YEARS
DR. DAVIS'S FAMOUS PILLS
HAVE BEEN UNIVERSALLY ADMITTED TO BE A BOON TO WOMANKIND.

THEY are the best known remedy for Anæmia, Giddiness, Fulness and Swelling after Meals, Loss of appetite, Hysteria, Palpitation of the Heart, Debility, Depression, Weakness, &c. Boxes, 9½*d.*, 1*s.* 1½*d.*, 2*s.* 9*d.*, and 4*s.* 6*d.* To be obtained from Chemists and Patent Medicine Vendors everywhere, or direct from
DR. DAVIS,
309, Portobello-road, Notting Hill, London, W.

From this we may perhaps conclude that the persons who supervise the advertisements of *Reynolds's Newspaper* have some regard for the risks which they may incur at the hands of the law. The advertisements which accompany that of "Dr." Davis in the same page negative any idea that the modification is due to regard for decency, while they suggest the manner in which "Dr." Davis's pills claim to be a "boon to womankind." The advertisements we have quoted are from issues dated March 3rd, 1901.

"ALL THE DIFFERENCE BETWEEN A LAWYER AND DOCTOR."

A CORRESPONDENT writes:—Your opinion on the facts stated below is asked for my guidance and for that of the firm of solicitors in question. In the autumn of 1898 I received a letter from a firm of solicitors at a distance asking me to give evidence in a case which was expected to end in a divorce respecting injuries inflicted by a husband upon his wife. This letter necessitated a search through the books of a practice held by me two years before. At least four letters were written, copies of which I now have. The case ended by some compromise and the firm of solicitors did not inform me of this. Some months after, hearing by chance that the case had been settled out of court, I sent a statement of fee, one guinea, due to me for the letters, &c., which I had written. The solicitors now raise objection to paying me on grounds part of which must be quoted for your comment. It reads: "In fact, we think it is somewhat unusual to charge for correspondence from a medical man." Half my fee has been offered which has been declined.

*** Our correspondent incloses two letters from the firm of solicitors. The first runs as follows:—

X *v.* X.

DEAR SIRS,—We had no idea whatever that you were going to charge for the information given us in this matter, as if you were the account should have been sent in at once when the matter was closed.

We have now no funds whatever out of which to pay this £1 1*s.*, so must ask you to kindly abate the account.

In fact, we think it is somewhat unusual to charge for correspondence from a medical man.

Yours faithfully,
———.

The second runs as follows:—

SIR,—We are surprised that you are not willing to meet us in this matter as most professional men would meet one another in a loss.

Legally speaking, we do not consider that you are entitled to any charge for correspondence telling us what you did for a Patient for whom we inquired years since.

You are simply entitled to charge for physic and attendances.

This is all the difference between a Lawyer and Doctor.

However, as you are not prepared to meet us, rather than prolong correspondence we send you our cheque for £1 1*s.*

Yours truly,
———.

We have no hesitation in saying that the solicitors are completely wrong in every respect. They had no business to expect that help would be given to them gratuitously. They complain that the account was not sent in when the matter was closed and yet they omitted to tell our correspondent when that happy event occurred. They are surprised that our correspondent will not make them a present of a guinea; they consider that legally speaking he ought to work for them for nothing; and they finally arrive at the mystical conclusion that all the difference between a lawyer and a doctor is that the doctor is "simply entitled to charge for physic and attendances." Our correspondent's charge was a low one as well as a fair one and the solicitors did well to pay it. They would have done better to have paid it at once and gracefully.—ED. L.

OPHTHALMIC STUDY IN VIENNA.

To the Editors of THE LANCET.

SIRS,—I intend going to Vienna in April for some months to study the eye. Would anyone who has been there kindly let me know (1) if the eye clinics go on all summer; (2) the hours and fees; and (3) where one could apply for a list of respectable apartments. I suppose summer is a good time to go to Vienna?

I am, Sirs, yours faithfully,
March 12th, 1901. VIENNA.

THE PROFESSIONAL GUIDE TO A QUACK.

To the Editors of THE LANCET.

SIRS,—Can an obvious quack legally retain on his staff "a duly qualified and experienced physician," and by advertising in the book he publishes that all communications requiring medical advice are not only submitted to, but are also under the personal supervision of this individual, thus induce people to part with their money for his so-called "remedy"? What steps can be taken to discover the identity of this "duly qualified physician," so that such conduct (which looks to me very like "covering" or associating with a pernicious quack swindle) may be inquired into by the proper authorities? On the other hand, if it be proved that there is, as a matter of fact, no one connected with the concern I refer to entitled to use the description of "duly qualified physician" as represented, and that the medical advice, both personally and by letter, is given by a gentleman whose highest qualification is "patent medicine vendor," what, then, is the proper remedy to prevent the "specialist" in question from carrying on his fraud by inducing people to place confidence in him by these false statements? Is the mere visiting (every few weeks) of a man supposed to be struck off the Register (if ever he was qualified to be on it), and as a matter of form putting his name to certain papers, sufficient to justify the statements published and enable the quack to evade the law and carry on his swindle with impunity? The favour of your advice will greatly oblige as I am in a position to disclose such information and details concerning a quack firm which, if made public, would prevent people throwing their money away on rubbish (at the best acidulated coloured water) and being gulled into believing that they are getting qualified medical

advice when they are only the dupes of an ignorant quack or worse. If this is not a subject you can afford the time or trouble to take up and investigate, can you kindly suggest a likely quarter where the matter may receive the attention it deserves for the protection of the public and the profession.

I am, Sirs, yours faithfully,

March 6th, 1901. AVIS.

*** If our correspondent will forward to us the information and details to which he refers we shall be in a position to answer his questions.—ED. L.

"MEMORIAL TO THE LATE DR. ARCHIBALD HAMILTON JACOB."

SUBSCRIPTIONS will be thankfully acknowledged by the following committee:—Sir Christopher Nixon (President of the Royal College of Physicians of Ireland), Mr. Thomas Myles (President of the Royal College of Surgeons in Ireland), Sir John Banks, K.C.B., Sir John William Moore, Sir William Thomson, Sir W. Thornley Stoker, Sir Charles A. Cameron, C.B., Sir Francis R. Cruise, Mr. A. O. Speedy, Dr. Lombe Atthill, Mr. Henry Gray Croly, Mr. Henry Gregg Sherlock, Dr. Stewart Woodhouse (General Prisons Board), Mr. Austin Meldon, D.L., Dr. Henry W. Oulton, Dr. Richard J. Kinkead (Galway), Dr. George M. Foy, Mr. I. Usher, Dr. H. MacNaughton Jones, Mr. A. A. Tindall, and Dr. M. J. Malone.

Amount already announced in THE LANCET—£259 6*s.* 0*d.*

Cheques and postal orders are to be made payable to the honorary treasurers (Sir Charles A. Cameron, C.B., 51, Pembroke-road, Dublin, and Mr. L. H. Ormsby, Vice-President of the Royal College of Surgeons in Ireland, 92, Merrion-square, Dublin), and crossed "Ulster Bank." The honorary secretary is Mr. George F. Blake, J.P., Registrar of the Royal College of Surgeons, Dublin.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Could you or any of your readers tell me of any private institution which would take and treat a severe attack of chorea?

I am, Sirs, yours faithfully,

W. LANGWORTHY BAKER, M.R.C.S. Eng., &c.

Moorcote, Eversley, Winchfield, March 10th, 1901.

AN ETHICAL POINT.

To the Editors of THE LANCET.

SIRS,—A has sold his practice to B. A was always looked upon as one of the "black sheep" by his low fees and other actions. B is following in his footsteps. C and D are the other medical men in the place and charge the ordinary fees of the district and are on the best of terms. B called on both on his taking over A's practice. C tried to persuade B to join with D and himself to form an ethical compact and fix fees, &c., and so work amicably together. B would not fall in with the proposal and is following on the same lines as his predecessor. C has not returned B's call and does not recognise B, nor did he A, professionally. D does by way of consultations and the like. Which of the two acts up to the recognised but unwritten laws of our profession? What would be the most feasible way to get each to a better understanding?

I am, Sirs, yours faithfully,

March 8th, 1901. GENERAL PRACTITIONER.

*** On the information laid before us in the above letter we should say that C's course of conduct is the better—that is to say, presuming that B acts unprofessionally in other ways than by lowering his fees.—ED. L.

"ARE THERE PINS WITH REMOVEABLE POINTS?"

To the Editors of THE LANCET.

SIRS,—In reply to a letter under the above heading in THE LANCET of March 2nd, p. 675, signed "Bandage," I do not think he will find pins "with removeable points," but why not remove the points himself with wire nippers? Such can be had in small size (as used by watch and clock makers) and if carried in the pocket will be always at hand when required. Better "see the point" than feel it.

I am, Sirs, yours faithfully,

March 11th, 1901. NIPPERS.

Jockey.—The resident within the district should not attempt to supersede the holder of the appointment without giving him notice of his intention.

L.R.C.P., L.R.C.S. is not recommended to apply for the post. See answer in our last issue to "A Subscriber to THE LANCET since 1886."

Centralisation.—When so many larger matters require to be dealt with we are not disposed to lay stress on the points.

Anxious.—We do not give medical advice. Our correspondent should consult his usual medical attendant.

Rusticus.—The dose of tuberculin for an average sized cow is three cubic centimetres—i.e., about 50 minims.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. During the week marked copies of the following newspapers have been received:—*Lincoln Gazette, Manchester News, Express (Notts), Stafford Advertiser, Dundee Advertiser, Cardiff News, Preston Post, Burton Evening Gazette, Glasgow Herald, Weekly News (West Bromwich), Midland Evening News (Wolverhampton), Newcastle Chronicle, Liverpool Daily Post, Bournemouth Guardian, Derbyshire Courier, Greenock Herald, Bury Guardian, Sussex News, Spalding Free Press, Leeds Mercury, Cheltenham Press, Hyde Reporter, Derby Times, Ipswich Times, Kentish Express, Birmingham Gazette, Oxford Journal, Scotsman, Norwich Press, Builder, Architect, Citizen, Pioneer Mail, Bristol Mercury, Yorkshire Post, Hong-Kong Telegraph, Sydney Morning Herald, Siam Free Press, Madras Standard, Daily Gleaner, Blackpool Gazette, Limerick Chronicle, Brighton Gazette, Morecombe Telegraph, Bath Chronicle, Walton Gazette, Bombay Gazette, Dorset County Chronicle, Sanitary Record, Surrey Advertiser, Mining Journal, Local Government Chronicle, Local Government Journal, Reading Mercury, Hertfordshire Mercury, Consett Guardian, Fife Herald, Luton News, Hitchin Journal, Tunbridge Wells Advertiser, Journal of Horticulture, Inverness Courier, Evening Post and Bulletin (Wellington, Australia), Chicago Packer, Daily Chronicle, Express (Whitby), Kettering Guardian, Durham Mercury, League Journal, Barnsley Chronicle, Times of India, Shipley Express, Warwickshire Times, Bucks Herald, Clitheroe Advertiser, Lloyd's Rugby Advertiser, Kent and Sussex Advertiser, Jackson's Journal (Oxford), &c., &c.*

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1900, which was completed with the issue of Dec. 29th, and the Title-page to the Volume were given in THE LANCET of Jan. 5th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1900, bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. **It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.**

Communications, Letters, &c., have been received from—

A.—Dr. J. Ackman, Guernsey; Aldershot Urban District, Medical Officer of Health of: Dr. J. Attfield, Watford; Messrs. Allen and Hanburys, Lond.; Angier Chemical Co., Lond.

B.—Mr. W. K. Brewer, Southsea; Bristol General Hospital, Secretary of Mr. S. H. Benson, Lond.; Herr R. Bär, Rothnauslitz; Mr. W. L. Baker, Eversley. Dr. J. Brownlee, Glasgow Birmingham University, Librarian of; Dr. C. W. Buckley, Lond.; Messrs. Bates, Hendy, and Co., Lond.; Bristol General Hospital, Secretary of; *British and Colonial Druggist*, Editor of.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnieres, Paris.

The Milroy Lectures

ON

PUBLIC HEALTH AND HOUSING:

THE INFLUENCE OF THE DWELLING UPON HEALTH IN RELATION TO THE CHANGING STYLE OF HABITATION.

Delivered before the Royal College of Physicians of London on Feb. 28th and March 5th and 7th, 1901,

By JOHN F. J. SYKES, M.D., D.Sc. EDIN.,
MEDICAL OFFICER OF HEALTH, ST. PANCRAS; LECTURER ON PUBLIC HEALTH, GUY'S HOSPITAL.

LECTURE III.[1]

Delivered on March 7th, 1901.

DOMESTIC CONVENIENCES.

MR. PRESIDENT AND GENTLEMEN,—Domestic conveniences provide, in proximity to the dwelling, for the supply of fresh water, the removal of soiled water and of excreta, and the temporary storage of refuse. The supply of water in its simplest form implies a draw-tap and drip sink; this enlarged becomes a wash-sink, and elaborated is inclosed in a scullery; this again by the addition of a copper becomes a scullery and washhouse. The draw-tap and sink are a mere matter of plumbing and may be placed anywhere convenient, but the scullery is a matter of construction and greater expense. Hence, according to the class of dwelling, it is found that the domestic water-supply may assume any of the above forms and may be without or within the dwelling, and may be in common or in sole use. A few general principles can be evolved from the various methods adopted. Draw-taps in common use are found placed on balconies, in lobbies, on staircases, in sculleries, and occasionally in water-closets—the last is a very objectionable situation. In sole use, they are found, in addition to the above, in the dwelling-room or in a scullery attached. The essential points to insist upon appear to be that in houses of flats there should be water-supply on each floor; that when the appliances are used in common they should not be overcrowded by users, but that separate provision should be made for at least every two dwellings or families, and that the supply should be either within the precincts of the dwelling or situated as closely as possible to the dwelling. When economy will not permit of sculleries or of sculleries of sufficient size or so constructed as to admit of washing coppers, it is usual to provide a common washhouse, either for the whole house, or for a block of houses, or for several blocks of houses; on the last scale they practically become public washhouses, to which hot and cold baths may be attached, the privacy with each step being diminished. One form of provision for washing found occasionally in working-class dwellings is very objectionable—namely, the placing of portable coppers in inclosed spaces without windows or other possible opening into the outer air; this opening should be a *sine quâ non*, and the steam vapours should also be shut off from the interior of the dwelling.

With reference to water-closets economy also dictates whether the construction of the dwellings shall be such as to include the water-closet within its precincts or exclude it, and whether it shall be in sole or common usage. By a by-law now applicable to all houses in London one water-closet must be provided for every 12 persons, and it is generally so arranged to provide the necessary water-closets on each floor in new flats, but it is not compulsory, although it should be so. It is also now provided by a by-law that a water-closet must not be constructed so that it is approached directly from any room used for human habitation or as a work-place, or for preparing or storing food. This ought not to be interpreted that by merely multiplying the number of doors the object of aerial disconnexion is necessarily attained. They must also now in all houses be constructed against an outer wall, and be ventilated by windows into the open air. In the regulations as to the designing of buildings approved by the London County Council on Dec. 3rd, 1889, it was provided that the doors of water-closets should open directly into the open air, and this was conveniently arranged by means of open lobbies, but now this precaution is no longer taken, and many water-closets open on to inclosed common staircases. It should be one of the essential points in houses constructed in flats that the water-closets should be cut off by open lobbies, the open lobby being utilised also as a place of deposit for the dust receptacle and any offensive matter. The Local Government Board in new buildings insist upon lobbies between water-closets and dwellings being permanently ventilated into the open air, and it is to be regretted that the London County Council should fill these openings in.

The London County Council has done so much good work in the construction of working-class dwellings that it might appear captious to take exception to certain points in the arrangements of some of them, were it not that every detail becomes of increasing importance with the increase in the size of domestic buildings and in the number of human beings which they house, and that the Council's buildings may be taken as models by many of the bodies that have constructed artisans' dwellings, many of which do not come up to the healthy standard set by the Council, and to which all the critical comments that have been made apply with much greater force in many instances.

The storage of refuse is a great difficulty, and it is to be regretted that it is not compulsory to provide a modicum of open space, lobby, or balcony on each floor level of dwelling-houses constructed in flats as a place of deposit for the dust receptacle and any offensive refuse as well as a means of access to the water-closet. The dust receptacle requires to be simply a portable metal bin. Dust shoots as a means of transferring the contents of individual bins into the common dustbin are condemned as abominations. For the dustmen to fetch bins from each of the many dwellings, in large houses several storeys high, and to empty them directly into the vans is impracticable on a large scale. It remains, therefore, for the occupier to empty at night or morning the private bin into the common bin or bins either by hand, or, in better-class houses, by hand-lift. By means of duplicate bins the common bin and any transfer of refuse can be dispensed with. It is indispensable that the public collection of refuse should be made daily from houses constructed in flats.

The water-supply and drainage of houses are governed by statutes, by-laws, and regulations that need not here be detailed.

ECONOMIES PRACTISED.

It is in the power of anyone to design and erect buildings, and the economies practised in designing dwellings may be briefly summarised as:—diminishing the width, increasing the length, and lowering the height of rooms, extending the number of rooms of a dwelling along one front, reducing the number and size or abolishing the open lobbies, reducing the number and size of the sculleries and washhouses or providing none, reducing the number of water-closets and wedging them in, increasing the number of storeys vertically and increasing their extension laterally, multiplying the number of dwellings on each floor by means of corridors and balconies, and increasing the height, depth, and breadth of the houses. Excess in these directions will require more regulation and control in the future type than has been exercised in the past type of house, as the effects of unhealthy conditions will be multiplied in proportion to the increase in size of the buildings and in the number of inmates.

The economies of usage, the overcrowding of rooms, dwellings, houses, domestic conveniences, and sanitary appliances, and the sub-letting and sub-dividing of houses and dwellings will also require more supervision to prevent deterioration.

Attention may be directed to the fact that construction and usage are more or less distinct from each other, and that whereas construction is permanent usage may be altered at any moment. Happily in London, under Section 211 of the Building Act of 1894, the conversion of dwelling-houses, dwellings, and dwelling-rooms from or to *other* uses cannot be made without alteration in conformity with the Act.

The resident superintendent, or caretaker, in "flats" is a great protection to dwellings whether occupied by the richer or by the poorer classes. In working class dwellings he selects the tenants, keeps the more unruly elements under control and the rents paid up without entangling

[1] Lectures I. and II. were published in THE LANCET of March 2nd (p. 599), and 9th (p. 679), 1901, respectively.

arrears; he keeps the parts used in common in repair and cleansed and sees that those parts used separately are kept cleansed and in order. He also performs the function of keeping out intruders from the common courtyard or common staircase, a great protection to the dwellings and the occupants. In Scotland the common stair is generally protected by a door with a special lock to which each tenant has a key. On the continent large houses built round courtyards with *porte-cochères* generally have a *concierge's* lodge at the entrance, and houses not so built are generally entered through the *concierge's* quarters. These forms of protection are generally absent in the tenement houses of London, to the disadvantage of both owners and occupiers—a doubtful economy.

CERTIFICATES AS TO NEW DWELLINGS.

In the metropolis a house newly erected or rebuilt cannot be occupied as a dwelling-house until the sanitary authority have certified that it has a proper and sufficient supply of water. No similar certificate is required as to the drainage, but by statute it must be laid as the sanitary authority order, and under their control and supervision, and sanitary conveniences must comply with the by-laws. There is no reason why a certificate should not also be required as to the drainage.

By the Customs and Inland Revenue Act, 1890, section 26, the assessment to inhabited house duty of any house originally built, or adapted by additional alterations, and used for the sole purpose of providing separate dwellings for persons at rents not exceeding for each dwelling the rate of 7*s.* 6*d.* per week and occupied only by persons paying such rents, shall be discharged by the commissioners, provided that a certificate of the medical officer of health of the district in which the house is situated shall be produced to them to the effect that the house is so constructed as to afford suitable accommodation for each of the families or persons inhabiting it and that due provision is made for sanitary requirements. The medical officer of health of a district on request by the person who would be liable to pay the house-duty on any house in the district if the duty were not discharged as aforesaid, shall examine the house for the purpose of ascertaining whether such certificate can properly be given, and if the house be constructed so as to afford such accommodation and due provision be made as aforesaid, shall certify the same accordingly. And by the Customs and Inland Revenue Act, 1891, Section 4, Sub-section 2 of Section 26 of the Customs and Inland Revenue Act, 1890, is amended by the substitution of the words "where the annual value of each dwelling shall not amount to twenty pounds" for the words "for persons at rents not exceeding for each dwelling the rate of 7*s.* 6*d.* a week and occupied only by persons paying such rents." In the case of any house originally built or adapted by additions or alterations and used, so far as the same is used as a dwelling-house, for the sole purpose of providing separate dwellings at an annual value not exceeding £40 for each dwelling, the commissioners shall, upon the production of such a certificate as is mentioned, grant relief by confining the assessment to the annual value of the house exclusive of every dwelling therein of an annual value below £20 (if any) and by reducing the rate of duty to 3*d.* The provisions of the sub-section in relation to a certificate apply to a certificate to be produced under this section. This certificate refers to construction and fitting and the medical officer of health must be guided not only by medical and statistical experience but also must have some knowledge of the construction of buildings, especially from the point of view of design and arrangement, so as to be able to form a reasonable opinion. It will be observed that the certificate is to be given after the building has been erected and occupied and that there is no proviso for the medical officer of health to peruse the plans of proposed buildings before this, much to the disadvantage of the owner, as he may be refused a certificate which some modification at the proper time might have justified. It will also be noticed that it is a most expansive and comprehensive certificate if the words of the Act are used only,[2] but the certificate should be framed in such a form as to define clearly the points to which it refers and how they are provided for.

In new buildings "originally built" to be occupied in separate dwellings the minimum requirements should be: (1) that the buildings are constructed in conformity with the building Acts and by-laws, especially as to damp courses, concreted basements, &c.; (2) that the water-supply is in conformity with the by-laws and regulations; (3) that the drainage is in accordance with by-laws and regulations; (4) that the common staircase is permanently ventilated at each floor level or by through ventilation, so as to break the common air-connexion; (5) that each dwelling is so arranged as to be through ventilated from one front to another; (6) that each of the habitable rooms is at least eight feet six inches in height and 96 square feet in area, and has a fireplace and chimney-flue; (7) that there is at least one draw-tap and sink, with a constant supply of water thereto, for every 12 occupants or less on each floor; (8) that there is at least one water-closet, properly and efficiently supplied with water, for every 12 occupants or less on each floor disconnected aerially from any dwelling in the interior of the building; (9) that on each floor a sufficient space or open lobby is provided accessible to, and for the use of, each family on each floor for the deposit of refuse, &c.; and (10) that accommodation for clothes-washing is provided sufficient for each family to occupy the wash-house or appliances one day each week.

In existing buildings "adapted by additional alterations" to be occupied in separate dwellings the minimum structural alterations for adaptation should require to be: (1) that the common staircase should be amply and permanently ventilated into the open air; (2) that the dwellings should be ventilated through from one front to another; (3) that the water-supply should be in conformity with statute, by-laws, and regulations; (4) that there should be a draw-tap and sink provided on each floor for every 12 persons or less; (5) that the drainage should be in conformity with statute, by-laws, and regulations; (6) that clothes-washing accommodation should be provided for each family at least one day a week; (7) that there should be water-closet accommodation for every 12 persons or less on each floor properly cut off aerially from the dwelling; and (8) that there should be an open lobby space or balcony on each floor as a place of deposit for the dust receptacle and offensive refuse.

I have never been asked to certify any existing building "adapted by additional alterations," nor have I heard of any such request being made elsewhere. It may be assumed that the return of inhabited house duty is not sufficient inducement to incur the expense of alteration. The house-duty is a tax from which there are many exemptions, amongst others houses under £20 a year are exempted from payment. The assessments are made by local authorities and for the purpose of rates every separate dwelling more or less severed from another is assessed as a separate "house." These assessments are forwarded to the surveyors of taxes and thus many houses containing separate dwellings are exempted. In addition, all houses with outside or open staircases are also exempted by the surveyor when the component dwellings come within the rentals mentioned in the Act. The number of dwellings requiring certificates are therefore becoming fewer every year.

III.—USAGE AND MISUSAGE.

DWELLINGS CLASSED ACCORDING TO USAGE.

Construction and misconstruction have been mainly touched upon as applying to new dwelling-houses; usage and misusage will mainly be considered in reference to old. Before doing so it will be desirable to picture dwelling-houses as falling into classes according to usage. On the one hand there is the ordinary dwelling-house occupied by one family or household and used as one dwelling only, and on the other the dwelling-house occupied by members of more than one family, and a greater or lesser part of which is used in common. Of these more or less common dwelling-houses there are a number of types:—1. Those used entirely in common—e.g., the common shelter and the common lodging-house. 2. Those used all in common except the sleeping places (*a*) with separate cubicles in corridors—e.g., Rowton lodging-houses, or poor men's hotels, or (*b*) with separate bedrooms—e.g., ordinary lodging-houses and hotels, boarding-houses, and residential clubs. These types of dwelling-houses are furnished, provided with service, and supplied with food, although this may be reduced to the smallest proportions, and they are variants of the inn or hotel, and are invariably under resident management and supervision and duly controlled as to usage.

[2] Tenemented Buildings and Duties on Inhabited Houses, Journal of the Sanitary Institute, vol. xix.

Then come dwelling-houses let in separate dwellings, unfurnished, without service and without food, and approached by a common stair, the dwellings differing in privacy according to the degree of structural severance and of combined usage of the domestic and sanitary conveniences, the types being :—1. Those containing separate and self-contained dwellings, each dwelling having but one entrance, and within its precincts at least room for sleeping, living, and cooking, and a scullery, lobby, and water-closet or other conveniences as in self-contained flats. 2. Those containing separate and self-complete dwellings in which part or all of the sanitary and domestic conveniences are situated outside the dwelling, but on the same floor, and are not used in common. 3. Those containing separate and associated dwellings where on each floor either the sculleries, lobbies, or water-closets or all the domestic and sanitary conveniences are used in association by the families on the same floor. These types are found with variants in all kinds of flats, but the next type is found in the older houses only. 4. Those containing dwellings having no severance from each other except by occupation and where the domestic and sanitary conveniences are used in common by all the occupants of the house. This last type is, of course, at once recognised as that of the misusage of the kind of house not intended for the purpose of providing separate dwellings, but which the pressure of population has forced into that service without any alteration to meet the changed usage. And here it is desirable to trace briefly the causes and effects of pressure of population upon housing and some remedies that have been suggested.

PRESSURE OF POPULATION AND OVERCROWDING.

In considering the question of overcrowding and housing there are certain lines that should be followed if logical conclusions are to be reached to diagnose the disease and to trace the causes, to lay bare the effects of the malady and the natural processes of recovery, to suggest remedies most assisting to natural events, and to remove any impediments to the return of equilibrium.

It must be borne in mind that overcrowding of population implies not merely the overcrowding of cubic space in rooms, but also the diminution in the number of rooms in dwellings and the increase in the number of dwellings in houses, the results of which are the production of overcrowding of the domestic and sanitary conveniences and the rapid deterioration educationally in the habits and customs of tenement dwellers and the ultimate deterioration of health, especially of the health of the children.

Briefly put, the malady is extreme pressure of population in certain areas of great towns, especially of the metropolis, the part most affected being the middle zone where the stream flowing in from the country meets the stream driven out from the centre. The extension of commercial and professional activity in the centre is the cause that sets in motion both streams, by bringing more and more workers to the centre and displacing more and more dwelling accommodation round the centre, so that both the displaced population and the newer comers compete for housing accommodation with those already residing in the middle zone. The effects are that the destitute are driven into the workhouses, the dissolute and the recessitous into the badly built, decaying, and out-of-date areas, and the respectable workers into tenements or rooms in dwelling-houses or parts of dwelling-houses from which the former better-class occupants have been driven farther out. Equilibrium has been restored in the past by the construction from time to time of additional dwelling-houses further and further out and the gradual improvement of means of transport, the largest proportion of those migrating to the suburbs belonging to the more comfortable and prosperous classes. There is no reason to suppose that this is not the mode in which equilibrium will ultimately again assert itself. But the process is slow and may be quickened by improved transport, by additional buildings in the outer zone and in the middle zone, by the reconstruction of the worst of the existing houses in healthy flats, and the adaptation into flats of the floors of the best of the remaining dwelling-houses.

There is an idea prevalent that if in an old area in a city so many thousand persons require decent dwelling accommodation it is only necessary to erect so many thousand houses on a new area in the country and to supply means of transportation and the transfer is effected. But thousands of people do not simultaneously put together their goods and chattels and straightway migrate some miles into the country. No such a movement takes place. The improved transport is not the means by which the overcrowded population of an internal area is removed, but is the medium that prevents the new area in the country from being isolated and enables those attracted there to get to and from the city. The new area attracts the best of the population nearest to it, and the areas relieved by the new area in their turn attract others. A movement and a circulation take place around the new centre. Additional transport and additional dwellings in distant suburbs will only relieve overcrowding in a particular area or zone by slow, distant, and indirect effect and it is difficult to understand why there should be any insistence upon building at a distance classes of dwellings that the overcrowded persons for whom they are intended will certainly not occupy when they are completed. These overcrowded persons will get the best accommodation they can secure within reasonable distance of their work, and as the pressure of population relaxes they will find this accommodation in the houses vacated by those of a somewhat better class moving further away.

Within the last 50 years London has grown yearly at the rate of from 40,000 to 50,000 persons, this average number being about equal to the excess of births over deaths; but a large emigration from London is continually taking place, and an equally large immigration into London simultaneously goes on. Whether the emigration is from the more central parts there is no means of ascertaining, but that the immigrants settle in the more outlying parts is proved by the census returns which show that the number of persons born out of London is larger in the outlying districts than in the inlying districts of London.[3] This leads to the question whether additional building in distant suburbs will immediately benefit the immigrants *to* or the residents *in* London?

It is very reasonably said that the demolition and reconstruction of unhealthy houses, groups, and areas are no remedies for overcrowding, and it is obvious that they cannot be as they do not provide additional dwellings. But the necessity for demolition and reconstruction is brought to an acute stage by overcrowding, the dwellings and groups of houses, originally ill-arranged and ill-constructed, being soon rendered unfit for habitation by the increasing congregation and compression of the worser elements of the population on an unhealthy area. The effect of demolition is not only to destroy the houses but also to disperse the worser elements amongst the better elements of the population. Therefore demolition is a remedy for the effects of overcrowding, and proper reconstruction should be the means of preventing their recurrence, and the effect of the process is a circulation and re-arrangement of population.

But there remains still to consider the large population driven into sub-let houses unsuited to the usage to which they are put. They never were intended to house a number of families and no attempt is made to render them fit for this purpose. It is here that overcrowding exercises its most deteriorating and permanent influence upon the health and morals of thousands of children, youths, and young persons whilst waiting for the erection of new buildings at a distance that will not affect their neighbourhood except by a back-wash years hence. I am firmly convinced that the greatest hope of regeneration lies in adapting the better type of tenement houses to the altered usage to which they are put, and without an effort in this direction, even when the acuteness of the overcrowding has been modified, the ill-effects will continue to persist.

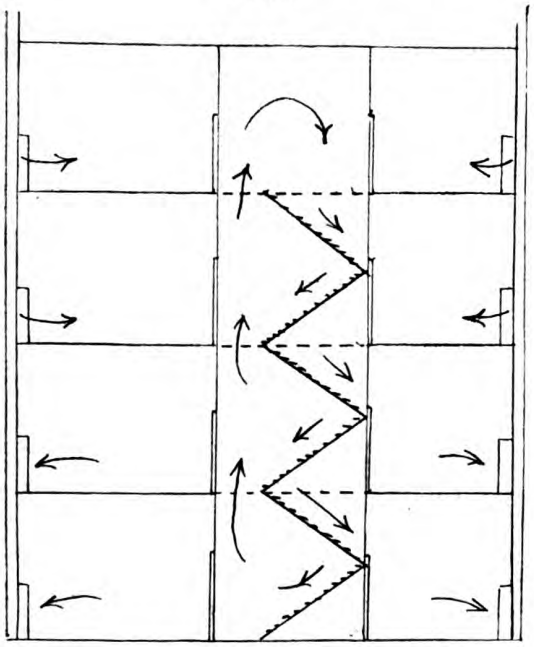
MADE-DOWN TENEMENT HOUSES AND TENEMENT DWELLINGS.

The tenement-house is generally understood to mean the ordinary vertical dwelling-house constructed for the use of one family and sub-let to the usage of many and not a house constructed in flats. Of such houses there are many thousands in London and a family likeness runs through them—the common passage and staircase and the staircase-well with its foul atmosphere derived from the rooms opening into it, and the dwelling-rooms with their doors ajar, destroying all privacy, in the attempt to mitigate the smokiness of the chimneys within (see Fig. 7 and Fig. 9). For the major part of the year, and especially in cooler weather, with the windows all closed and the fires all burning, the atmosphere of the whole house becomes one, and as no air can enter by the windows or chimneys and the fire-grates are all extracting, the chimneys as a consequence all smoke, much to the surprise and

[3] See also Map, vol. ii., Labour and Life of the People, Charles Booth.

disbelief of the owner, who previously to sub-letting the house probably lived there himself. He cannot understand the competition that is going on between his tenants to secure as much as possible of the air in the staircase-well, wherever it may be drawn from, and that whereas formerly the unlighted grates supplied air to the staircase-well which was distributed up and down the staircase by an upcast and downcast current to satisfy the lighted grates, those grates being now lighted and becoming also extractors the circulation of air in the house is destroyed. That this is the case can be verified by very simple experiments in any house by means of candle flames and smouldering paper.

FIG. 7.



A diagrammatic representation of the circulation of air in ordinary dwelling houses.

The absence of cleanliness everywhere, especially on the upper floors, and the want of use of soap-and-water are everywhere apparent, and a little deeper inquiry leads to the conclusion that water is not a commodity to be obtained easily without going a considerable distance, and that to get rid of liquid and solid refuse similar long journeys have to be made. In addition to the excessive number of dwellings in the house there is usually an excessive number of persons per room, but it is remarkable how closely the occupants keep just outside the inadequate minimum of cubic space. So that with no illegal overcrowding these unhealthy conditions are the normal ones under which many thousands are permanently housed and will continue to be so housed whatever new additional building takes place in the suburbs. The superficial observer often heaps abuse upon the class occupying such houses for their negligent, uncleanly habits, oblivious of the fact that the constructive arrangements of their dwellings never give the opportunity of acquiring decent habits.

Many years ago the late Dr. Edmund Parkes showed that, calculated on a physiological basis, the human adult required 1000 cubic feet of space, because in order to maintain the air in a sufficient state of average purity in a dwelling-room it was necessary to supply 3000 cubic feet of air per hour and the air in this climate could not be changed more often than three times per hour. We are continually bemoaning the large death-roll of tuberculous phthisis, which is, as we have seen, essentially a disease spread by crowding and restricted air-space, and the medical profession is now strongly advocating the cure and mitigation of the disease by fresh-air treatmeat. Is it out of place to advocate even more strenuously the prevention of the disease by the provision of more cubic space and especially by raising the present inadequate minimum standard of 300 cubic feet? The adoption of a maximum as a working standard is scarcely practicable, but it is practicable to advance the minimum standard to 400 cubic feet at the very least for adults, and if the lauded fresh-air treatment means anything it means, firstly, a decided step in this direction and a legal definition of overcrowding, the omission of which in our Public Health Acts is a serious flaw.

How are local authorities to control new buildings as to cubic space occupied after they are constructed, since overcrowding is not a question of construction? It can only be done on a sufficient scale by a statutory definition of overcrowding of cubic space, and nothing short of 400 cubic feet per head for adults will be satisfactory, although it may reluctantly be reduced to half the amount for children under 10 years. It is essential to practical working that this minimum standard of cubic space be made to apply to all rooms used for sleeping purposes, whether occupied also as living-rooms or not, because it is practically impossible in a large number of cases to differentiate, and where such differentiation is attempted it fails in that it has no permanency.

Underground dwellings are mainly to be found in tenement houses, where they were originally intended to be used as kitchens, sculleries, stores, lumber-rooms, or cellars. Underground rooms are only subject to restrictions when they are let as dwellings separately from any other rooms on any floors of the house, and when the floor of the rooms is more than three feet below the surface of the nearest ground. The principal disadvantages these rooms suffer from are want of light and air and the presence of dampness and ground vapours, and the restrictions are intended to avoid these. It is inscrutable why the legislature has hesitated to prohibit any room from being used as a dwelling however much or little the floor may be below the surface unless protected by a concrete base and an external area to six inches below the base level with ventilation between concrete and flooring. Numbers of back basement rooms escape the statutory provisions intended to protect against damp earth and ground vapours, simply because their floors are less than three feet below the nearest ground, which is generally a diminutive backyard. The principal reason for mentioning underground dwellings here is to illustrate the fact that Parliament has in this instance legislated for the dwellings as apart from the houses as a whole, and has set a precedent that should be followed by legislating for other dwellings in houses let in separate dwellings, and defining what is a proper dwelling, for at present no such definition exists. Whole streets of houses formerly occupied by good-class families are now occupied in separate dwellings on separate floors. Whole neighbourhoods of houses in London can be seen undergoing this process of subdivision, and their state slowly but surely falls from bad to worse without any attempt to stem the deterioration, degradation, and unhealthy results that must inevitably follow until an insanitary area will have to be dealt with at great expense. There are no powers available for dealing with the structural arrangements of separate dwellings, and the only course open is the registration of the whole of the house under the by-laws.

There can be no doubt that the want of stair ventilation, the difficulties of obtaining water, of access to the water-closet, to the scullery, and to the washhouse, and of refuse riddance, are causes of the ill-health of the dwellers in tenement houses, and that the unhealthy habits engendered by such conditions become permanent.

THE REGISTRATION OF TENEMENT HOUSES.

Every sanitary authority must make and enforce by-laws for fixing the number of persons who may occupy a house, or part of a house, which is let in lodgings or occupied by members of more than one family, and for the separation of the sexes in a house so let or occupied; for the registration of houses so let or occupied; for the inspection of such houses; for enforcing drainage for such houses and for promoting cleanliness and ventilation in such houses; for the cleansing and lime-washing at stated times of the premises; and for the taking of precautions in case of any infectious disease. With reference to infectious disease and drainage, all houses, including the above, must conform to the laws, by-laws, and regulations that already sufficiently cover that ground. Therefore, there remain with regard to tenement houses the provisions for registration, inspection, air-space, ventilation, and for the cleansing of parts and of the whole premises. The same by-laws apply to a house whether it contains two

families or a dozen. As far as ventilation is concerned the model by-laws of the Local Government Board make no structural provision, so that the principal use of the by-laws is to prevent overcrowding and to obtain cleansing. The essential point of difference between the condition of a house when it contains two and when it contains a dozen families is one of altered usage with unaltered structure, and the by-laws provide for no structural alteration; on the contrary, by registering the house the misusage of the premises for purposes for which it was not built is practically stereotyped and legalised. This is remarkable as contrary to the spirit of the Building Act which by Section 211 (3) prohibits the conversion into or use as two or more dwelling-houses any building constructed originally as one dwelling-house. The unit of legislation has hitherto been the house, except in the case of underground dwellings. With the altered method of construction of new dwelling-houses and of usage of old houses the house as a unit is insufficient to meet the requirements of separate dwellings under the existing form of laws and by-laws. The unit must be the dwelling. This is so obvious a generalisation that it would hardly need statement but for the fact that it appears to have almost entirely escaped the observation of the legislature, possibly because the floor and flat style of dwelling, one storey above another, is the growth of recent years.

A COMPARISON OF FLOORS WITH FLATS.

If dwellings in floors be compared with dwellings in flats there is a great difference in the conditions of living. "Flats" we understand to be horizontal dwellings with all conveniences on the same level; "floors" we understand to be horizontal dwelling-rooms with all conveniences on ground or basement level. The conveniences embrace (1) water-supply for (*a*) personal ablution, (*b*) cooking and washing up, (*c*) small washing, (*d*) room washing, and for (*e*) drinking purposes; (2) drainage for water polluted by (*a*) personal ablution, (*b*) food washing, (*c*) small washing, (*d*) washing of rooms, (*e*) bedroom slops, (*f*) urine, and (*g*) children's excreta; and (3) refuse removal, including food waste, ashes, and sweepings. The small washing is often done in a room, but the large washing is usually done in the washhouse on the premises or at the public washhouses or by a laundress. The coal fuel is kept either in or in close proximity to the dwelling.

Certain houses that enable exact comparisons to be drawn between the sanitary condition of these two modes of living—namely, in flats and in floors, have come under my observation in adjoining streets. Both groups were built in 1882–83. For convenience the former may be called A, B, and C houses in O street and the latter Nos. 2 to 20 (even numbered) houses in H street. Each group contains 42 dwellings; the flats are contained in three houses, each consisting of 14 dwellings of three rooms each. The floors are contained in 10 houses, of which eight consist of a three-room and a two-room dwelling each, one of one three-room and four two-room dwellings, and one of five two-room dwellings. The houses are in each group of four storeys, the "flats" being four on each floor and two on an additional half-ground floor at the back. In none of the houses of either type is there a resident caretaker. The fundamental difference between the two groups is that whereas in the "flats" all conveniences are on the same level in the "floors" the conveniences are situated in the basement or yard, and the question to be asked is, What effect has this upon the habits of the occupants, especially the occupants of the upper floors? To avoid entering into lengthy details two typical cases may be taken to exemplify the comparative sanitary conditions that prevail in the two kinds of houses. In the top floor of C house in O street is a family of husband and wife and five children, paying 8*s*. a week for a dwelling consisting of a living-room, two bedrooms, a scullery and a washhouse, and a water-closet, and kept in an orderly and cleanly condition. In the top floor of No. 10 house in H street is also a family of husband, wife, and four children, paying 8*s*. 6*d*. a week (6*d*. more) for a floor consisting of a living-room and two bedrooms. Every drop of clean water has to be brought up from the basement and every drop of dirty water taken down again. The washing is all done in the basement washhouse. All refuse is thrown into the fire-grate and there kept until ready to be taken down to the dustbin in the yard. All the members of the family, including very young children, have to make their way down to the back yard to the water-closet. The tenant did not know any of the other families living in the house, whether they were respectable or not. The condition of the rooms left much to be desired, although the mother appeared to be an industrious woman and deplored the fact that she had been obliged to move out of one of the flats in O street because the house had been devoted to other purposes.

There is a vast number of families in London living on the top floors of four-storeyed houses, the water-taps, sinks, water-closets, and dustbins of which are situated at the ground floor or basement, or in the yard or area, and these houses are about 40 feet high. It is usually assumed that 20 times more energy is expended in walking upstairs a vertical height in comparison to walking on the level; therefore walking to the top of a four-storey house is equivalent to walking about 800 feet upon the level, and, say, a cottage measures 15 feet frontage, this is equivalent to walking past a row of over 53 cottages to reach the common sanitary conveniences above-mentioned. What would be the opinion of a medical officer of health or of the Local Government Board if provision were as inadequately made even in a rural district? Yet this is the condition that prevails over a large part of London. It is usual to regard 100 feet horizontally as the limit of "reasonable distance" for water and drainage, and even the extreme limit of the law does not suggest going beyond 200 feet. This is equal to five feet and 10 feet respectively regarded vertically, or one storey. How can it be said that houses in which some of the families have to traverse a distance equivalent to 1600 feet to and fro to draw fresh water, another 1600 feet to and fro to cast foul water, 1600 feet to and fro (every member of the family, including very young children) to visit the water-closet, and another 1600 feet to and fro to deposit the refuse if it is not to be retained in the dwelling-rooms, are sufficiently equipped structurally to give the occupants an opportunity of leading healthy, cleanly lives? What chance has a respectable family of observing the decencies of life in a house where there are one or two dissolute families, where the domestic and sanitary conveniences are all used entirely in common, and the members of the respectable family, even the youngest, are continually traversing the house to and fro? If domestic and sanitary conveniences are provided on each floor those living on that floor can at least cultivate their own good habits in their own way. What is wanted is to procure for families as much privacy as can be obtained, and to reduce the common usage to the smallest proportions possible. This is even more requisite in tenement houses where there is no resident controller than in blocks of artisans' dwellings. Numerous streets in parts that were suburbs 50 years ago with good middle-class houses are now sub-let in floors. I have watched the conversion of whole streets and roads of good houses from one occupation into "floor-lettings," and this has taken place within recent years and without the least modification of structure. The ultimate effects of this conversion without adaptation is disastrous. The leasehold system is partly responsible for it, the leaseholder naturally getting the best return possible, and the freeholder being supine, as the demand for housing accommodation forces up the value of the land. The ultimate result appears never to be considered until insanitary conditions throw upon the sanitary authority, and especially upon the medical officer of health, the unpopular duty of condemnation. This shifting of responsibility throws upon the medical officer of health the defensive duty of pointing out that he is largely required to make bricks without straw, because the domestic and sanitary requirements of a dwelling, as distinguished from a house, are undefined, and the ordinary laws as to nuisances do not touch the points at issue.

With the increase in the size of dwelling houses and the increase in the subdivision of houses into separate dwellings the urgency of legislating on the lines of the dwelling as the unit becomes greater and greater, and no approach to any satisfactory handling of the housing question, at least in the metropolis, will ever be reached until this unit is adopted as a fresh starting basis. Some such provisions as the following are required to meet the changed circumstances of living. Every part of a house hereafter let off separately as a dwelling shall have on the same or on the adjoining floor the use of the domestic and sanitary conveniences necessary to render a dwelling habitable. The domestic and sanitary conveniences, the use of which is necessary to render a dwelling habitable, are: a water draw-tap constantly supplied with water, a sink and waste-pipe for drippings and washing purposes, a water-closet, dust receptacle, coal-box, and food-safe.

None of these conveniences should be situated in a habitable room, and where possible there should be an open lobby or landing on each floor. In any case the common staircase of the house must be permanently ventilated into the open air at each floor level. It should be remembered that in continental and Scotch cities, where for years the flat system has been in vogue, the mode of sub-letting houses in floors improperly equipped does not present itself as a serious question for them, as on each floor of the houses of those cities the appurtenances of the dwelling are provided. It is the altered conditions in London that furnish this serious problem.

THE ADAPTATION OF TENEMENT HOUSES.

It may be taken that there would be little difficulty in making and enforcing provisions for ventilating the common stair at each floor level, for having a refuse receptacle on the open landing or lobby, and for supplying a draw-tap and sink on each floor. The water companies might possibly stand in the way with extra demands, and the owners of tenement houses would probably object to any expenditure unassisted.

With regard to water-supply it was pointed out by the last Royal Commission, in reference to the metropolis and neighbourhood, that "the requirements of the population are a supply of pure and wholesome water, constantly laid on, at such a pressure as will make the water reach the top storey of the highest houses, and in quantity sufficient from time to time to meet the needs of the growing number of inhabitants."[4] Very few made-down tenement houses have water supplied anywhere above the ground floor, and generally it is in the basement only, or sometimes at the end of the backyard. The only way in which the approval and coöperation of property owners could be won would be by monetary assistance in some form. If this were forthcoming something more permanent than the mere makeshifts above suggested would be required of house-owners, and if municipal authorities were to undertake to convert floors into "flats" the same would apply. For the purpose of adaptation only houses well situated as to light and air should be dealt with. It must be recognised that a certain proportion of houses are not fitted to be adapted, either on account of the surroundings, or of the internal arrangements, or of the originally bad construction, so that it would be necessary carefully to select those suited to the purpose, but of these there are considerable numbers.

There are three methods in which tenement houses could be adapted. 1. The simplest but not the most satisfactory manner is by partitioning off a portion of the front room opposite the staircase landing on each floor to form a scullery and washhouse and on the further side of this to construct a water-closet against the outer front wall, obtaining through ventilation from the open air in the front to the back of the scullery by means of a fanlight on to the common staircase and so into the open air again off the staircase at the rear of the house. This partitioned off lobby, scullery, and water-closet may be made to be entered either from the front room of the dwelling for private use or from off the staircase for common use when there is more than one dwelling on a floor. (Fig. 8A.) 2. Probably the best method would be by the construction of a tower at the back of the house, containing on each floor an addition containing an open lobby, scullery, and water-closet and approached from the back room on each floor; this would restrict the addition to private use. (Fig. 8B.) 3. If the tower were constructed off the staircase then the addition on each floor or half floor would be available for common usage by the families on the adjoining floor. (Fig. 8C.) Out-buildings, towers, or projections abutting at right angles to the line of frontage, generally the rear front, are objectionable on account of the tendency to impede light and air in proportion to the distance they advance from the main wall and according to orientation. On the other hand, there is a great advantage in being able to add sanitary conveniences, such as water-closet, scullery, &c., and lobby, with ventilation between the dwelling and the sanitary additions, provided that the projections do not advance so far as to close in the spaces at the rear or to interfere with the perflation of the dwelling. I see no reason why a skilful architect should not be able to design a tower addition of this kind without any appreciable detraction from light and air. The sketches show the several methods suggested and sections through a tenement house unadapted and adapted for separate dwellings. (Fig. 8A, Fig 8B, Fig. 8C, and Fig. 9.)

After working for a long time upon this idea of adapting the ordinary tenement house so as to render it healthily habitable in separate dwellings, I recently found, as many before have found, that there had been another worker in the same field. 30 years ago Professor Bannister Fletcher, F.R.I.B.A., published a work entitled "Model Houses for the Industrial Classes," which is now out of print. The work contains three designs[5] for model houses, one of which there would be great objection to, another that would be passable with slight improvement, and a third that is decidedly good. But the most important part relates to the adaptation of existing houses, of which two methods are shown by drawings—namely, the addition of domestic and sanitary conveniences on each floor—by one method placing them in a separate compartment on the staircase and cut off from the front room, by the other method placing them in a tower built out at the rear of the staircase window. There is also illustrated a method of converting three narrow houses into two "double flat" houses. This work was written with a view to realising increased profits from the rentals of adapted houses, but as unadapted sub-let houses obtain as high and even a higher rental per room than houses constructed in small flats it is not surprising that the object in view was not attained. Yet the fact remains that adaptation is undoubtedly the right and proper course to pursue in appropriate instances, and is the only means of permanently ameliorating the condition of existing tenement houses.

The raising of the money for this purpose with local authorities presents no difficulty, as under Part III. of the Housing of the Working Classes Act, 1890, a local authority as well as a private company, association, or individual may not only build additional houses, but may also convert any buildings into dwelling-houses for the working classes and may alter, enlarge, repair, and improve the same respectively. No effort has hitherto been made to do this. The best work that local authorities might hope to do would be in showing by example how some existing unhealthy tenement houses could be converted into healthier flats as object lessons, rather than in attempting to acquire and improve *all*

[5] There is a fourth but it is practically the same as the third.

such houses. Private owners, individually and associated, must be depended upon to carry out such work, if it is to be done on any adequate scale. As to borrowing money for the construction of new dwellings I have shown elsewhere[6] that public authorities and private

companies or individuals have both borrowed nearly equal amounts from the Public Works Loans Commissioners for this purpose. No money appears to have been borrowed for purposes of adaptation. Under Part III. of the Act loans are granted to private persons entitled to the land in fee simple for an absolute term of more than 50 years for the purpose of improving dwellings for the working classes. Land-owners have no power to deal with the houses on their land until the leases expire—leasehold house-owners only possess this power, although even they in many instances are not the persons who sub-let the houses in subdivided tenements. Few leasehold house-owners possess houses upon a term sufficiently long to satisfy the requirements of the Public Works Loans Commissioners for borrowing purposes, and most leasehold house-owners would object to borrowing or spending money to adapt tenement houses when they can be let without alteration.

The exemption from the inhabited house duty offered by the Customs and Inland Revenue Acts of 1890 and 1891 under the certificate of a medical officer of health to owners of houses altered and adapted to be let in separate dwellings has not, to my knowledge, proved sufficient inducement to cause a single owner to move in this direction. As has been already pointed out, the pressure of sanitary legislation in this direction is *nil*, such legislation not yet having taken into account the altered circumstances of the last 10 or 20 years.

It might be thought that if new blocks consisting of houses containing flats of two, three, and four-roomed dwellings with conveniences attached can be erected and be let at the same rent as, and even at less rental than, the same number of rooms in an existing house subdivided and sub-let without conveniences attached to the separate dwellings it should be possible to adapt many existing houses without necessarily increasing the rental, and to stem the downward progress of deterioration in decorative and structural condition caused by common usage, and at the same time to improve the habits and to stimulate the self-respect of the inmates, to the mutual advantage of landlord and tenant. But one has to recall the circumstances in which many of the existing blocks of separate dwellings were erected in London. The Metropolitan Board of Works never built on any of the numerous sites cleared by them since 1875, but the sites were sold at a price much below open market value, because the condition was attached to the sale that working-class dwellings must be erected upon the sites, and the companies and individuals who purchased them were to that extent practically subsidised. A similar course is adopted by the London County Council as successors of the Metropolitan Board of Works: they build upon the sites cleared, but before doing so they revalue the sites with the restriction upon them only for the building of working-class dwellings, and the difference between the open market commercial value and the restricted value is wiped off, again practically subsidising the dwellings upon the site. Furthermore, some bodies that construct buildings have been largely endowed by private philanthropy, so that they have no interest and no sinking fund instalments to pay, and are to that extent also subsidised. Therefore it is not to be wondered at that well-found flats are let to the working-classes at the same or a lower rental than bare incommodious floors in tenement houses and that house-owners are deprived of whatever inducement or incentive or desire they may have possessed properly to adapt houses made down into tenements to the altered purposes to which they are put.

At present there would appear to be only one way of counteracting the effects of subsidies or quasi-subsidies upon new buildings, and that is by subsidising or otherwise assisting pecuniarily the existing owners of houses made, or to be made, into tenement houses. If local authorities undertook to alter and adapt tenement houses they would have to purchase them compulsorily with 10 per cent. added.

If owners undertook to adapt and improve tenement houses so that they might be let in separate dwellings in properly equipped floors or flats they might be empowered to send to the borough councils plans and sections of the proposed improvements, to be submitted to the surveyor and medical officer to report upon. This report would embrace the consideration of open space about the buildings for external light and air, the height of the houses, the condition of stability and repair, the mode of construction and arrangement, the suitability of the premises to adaptation as separate dwellings, and the adequacy of the proposed improvement to convert the floors into healthy flats. If the owners' houses and plans be approved they might be empowered to make application to the borough council for loans upon the property at the lowest possible rate of interest with repayment by small instalments in a term of years, in a similar manner to that in which a land-owner obtains a loan from the Public Works Loans Commissioners for the building of new working-class dwellings. The conditions upon which the loans would be granted would be set out fully as to the structural improvements to the premises required before completion of the payment by the borough council. In addition to the benefit of a very low rate of interest and a small refunding charge, the certificate of medical officers of health would exempt the house also from inhabited house duty. By some such method owners might be induced to adapt their houses to the altered requirements in many areas vacated by emigrants to the suburbs. If not, then some small additional inducement should be offered to bring about the necessary equilibrium. Otherwise there appears to be a prospect that if the number of houses made down by usage into floors without structural adaptation continue largely to increase the number of sanitary inspectors and the amount of inspection will require also to be largely increased. Judging by the very much less inspection required in "flats" as compared with "floor" houses, even where there is no resident caretaker, it is not unreasonable to expect that the adaptation of the "floors" would enable a considerable annual expenditure to be saved and that the beneficial effect upon health and habits of the people so housed would make ample recoupment in kind, if not in money, for the expenditure incurred in adaptation. In any case it must necessarily be in appropriate instances a less costly procedure than entirely demolishing the houses and reconstructing them.

[6] Results of Housing the Working Classes, Howard Medal Prize Essay, Royal Statistical Society, 1901.

A BRIEF REVIEW OF THE HOUSING QUESTION.

To summarise briefly the question of the healthy housing of the people, our ideas must be cleared of the confusion between the march of two cognate but distinct events. The first is the pressure of urban population whereby all the requirements of healthy dwellings are compressed into the smallest limits, and the second is the making down and dilapidation of dwelling-houses and the deterioration of the health of the inmates whereby insanitary areas and unhealthy tenement streets are created. The remedy for the first is relief of the pressure and resistance to its injurious tendencies; the remedy for the second is the reconstruction of insanitary areas and the adaptation of tenement houses. The relief of the pressure of population will ultimately be brought about by the improvement of the means of transport between the suburbs and urban centres; the building of additional houses in the suburbs; the attraction to the suburbs of the better classes and those able to live at a distance; and the slow but ultimate relief of the pressure in the middle zone by the movement and circulation of the population and the gradual vacating of houses occupied by single families and sub-letting in separate dwellings. The remedy for the dilapidation and deterioration will be brought about by the reconstruction of the worst areas and houses in healthy flats; the adaptation of the best streets and houses of an unhealthy "floor" type to a healthy "flat" form of construction to suit the altered mode of usage; and the supplementing of sanitary laws and by-laws with the dwelling as the basic unit.

The Lettsomian Lectures

ON

DISEASES AND DISORDERS OF THE HEART AND ARTERIES IN MIDDLE AND ADVANCED LIFE.

Delivered before the Medical Society of London

BY J. MITCHELL BRUCE, M.A., LL.D. ABERD., M.D., F.R.C.P. LOND.,

PHYSICIAN TO CHARING-CROSS HOSPITAL; CONSULTING PHYSICIAN TO BROMPTON HOSPITAL FOR CONSUMPTION, &C.

LECTURE II.[1]

Delivered on March 18th.

MR. PRESIDENT AND GENTLEMEN,—In my last lecture I presented to you a brief account of the condition of the organs of circulation between the ages of 40 and 75 years and I then proceeded to direct your attention to the principal influences which may disorder and damage them during that period of life. I will now attempt to describe the clinical characters and course of the affections of the heart and arteries as I have observed them in connexion with these different influences respectively, whether gout, mechanical stress, syphilis, or other. Thereafter, if time permits, I may be able to examine the different symptoms and signs individually in order to discover the value of each as a guide in diagnosis.

Now, as I have already pointed out, the causes of cardio-vascular disease in the second half of life are very often, indeed usually, complex. It follows, therefore, that if we desire, as we do most particularly, to discover the effects of each pathogenic influence as distinguished from the others, we must begin our study with the simplest, or purest, or most definite of all, and proceed from it towards those which are more difficult, as well as to combinations of causes. It is easy to adopt that method in our present inquiry.

TOBACCO-HEART.

We have in tobacco a single distinct influence at work, one that is universally acknowledged to affect the heart and vessels, and the physiological action of which is understood; one, further, that can be removed, perhaps not without some difficulty (for I have had a patient plead for his pipe with tears in his eyes), and certainly can always be resumed with remarkable readiness; in a word, a most favourable subject of observation by experiment. It is well, too, to begin the study of tobacco-heart in young men whose circulation is still structurally sound; and thereafter to follow up the subject in middle-aged and old persons. Adopting this line of inquiry, I have found that the uncomplicated effects of tobacco on young healthy hearts as they present themselves clinically are palpitation in every instance, a sense of irregular action,[2] post-sternal oppression and pain in half the cases, and in one out of every eight sufferers either angina or uncomfortable sensations in the left arm. Faintness or actual faints occurred in one-third, and giddiness and a feeling of impending death in a smaller proportion. Turning to the physical signs, the heart proves to be of ordinary size in 50 per cent. of the patients; in a few it is very slightly enlarged; the præcordial impulse is often very weak, but occasionally increased in force and frequency and almost as often irregular as not; the pulse tension, with insignificant exceptions, I have always found low. Very interesting, in the light of what I shall tell you later, is the fact that out of 20 of these patients complaining of the heart not one presented a cardiac murmur beyond a weak mitral systolic bruit, varying with posture or cubitus.

Now we are in a position to study the tobacco-heart in a man, aged 40 years; and again let us begin with a man who is sound, active, and healthy otherwise. He complains of his heart, and recognises willingly (for he belongs to our own profession) in the discomfort and anxiety from which he suffers the penalty of having smoked for years the strongest and blackest tobacco that he could buy. Yet his heart is not enlarged, and the cardiac sounds may be described as ordinary were they not peculiarly irregular, the frequency changing every moment and a falter occurring at short intervals. There is not a trace of murmur to be found in connexion with the valves and orifices. At ages over 40 years a clinical study of the tobacco-heart is highly instructive from a practical point of view. Whilst palpitation is still the common complaint, pain, including angina, is put forward more prominently, and so are faintness, actual faints, a feeling of impending death, and a sense of cardiac irregularity, each intermission being accompanied with a sudden stab through the præcordia. In these subjects the heart is more frequently found to be large and feeble, the same weak systolic murmur is occasionally to be heard, the radial pulse is often irregular, and the vessel-wall is thick. This, you will notice, is a combination of symptoms and signs sufficient to alarm the casual observer. But when we examine it more deliberately, in the light of our study of the tobacco-heart in young subjects on the one hand, and of our knowledge of the normal or natural condition of the heart and arteries at 60 years of age on the other hand, we are able to reassure ourselves and our patients. We are justified in concluding not only that every cardio-vascular lesion which may happen to be found in tobacco-smokers is not to be put to the credit of tobacco, but *vice versâ*—and this is of more interest to us in our present inquiry—that præcordial pain, angina, faintness, and irregular pulse in a man, 60 years of age, with a full-sized heart are not to be hastily regarded as evidences of grave disease without further inquiry as to his habits. The cardiac enlargement and large pulse may be nothing more than the result of a life of bodily and mental activity; the præcordial distress may be the result only of tobacco. How very necessary this caution is will be impressed upon your consideration by the two following cases. The first is that of a man, 60 years of age, actively engaged in professional pursuits, who first suffered from præcordial pain of an alarming character four and a half years ago and has had attacks since, particularly during exertion and after meals. One day last autumn, at the end of many hours' hard work, accompanied by at least 18 cigarettes, he was rushing off to dine with a friend when he was suddenly seized with præcordial pain, which he described as fearful, radiating down the left arm. He broke into a cold sweat, thought that his last hour had come, and for a short time had impairment of consciousness. Shortly after this event he took the advice of his medical men and gave up tobacco—shall I say for a time?—and from that day to this, now six months, he has had no further trouble with his heart. The second case

[1] Lecture I. was published in THE LANCET of March 9th, 1901, p. 692. Lecture III. will be delivered on April 1st.

[2] A medical friend who has suffered from tobacco-heart assures me that at one period he could distinguish the contractions of the auricles and ventricles.

is equally striking. A man, aged 55 years, of fairly active disposition and somewhat full habit of body, was suddenly seized with angina pectoris in October. 1899. The pain was of a dull bursting character over the region of the heart; and it passed into the left shoulder, down to the elbow, and settled particularly in the wrist. At the same time there was pain in the upper maxillary region. The heart slowed down from 75 to 50, and the sufferer felt that he was dying. From that time anginal attacks occurred in rapid succession, five, six, nine, or even 11 in a single day; occasionally they came on in the night. This experience continued for nearly two months on end; indeed, it was six months before the angina finally ceased. It was instantly relieved with amyl nitrite; nitro-glycerine was unsuccessful. In the course of giving advice to this patient I fortunately discovered that he had just laid in a stock of 2000 cigars. The line of treatment was obvious, and the result has been, as I have said, complete recovery.

I have dwelt on the subject of tobacco-heart perhaps longer than was necessary, addressing, as I am, a meeting of practitioners of experience and not a class of clinical students. I have done so to bring home to us an important consideration which we are all apt to overlook in diagnosis and still more in treatment—namely, that whether in an ordinary senile heart, or in a heart that is the seat of chronic valvular disease, or in arterial degeneration, something more than the pathological changes have in many instances to be regarded—usually some entirely adventitious disturbance which alone calls for treatment, such as indigestion, flatulence, worry, a bronchial catarrh, or it may be free indulgence in tobacco, tea, or coffee.

THE HEART IN ALCOHOLISM.

Let us pass on now to consider from the clinical point of view the effect on the organs of circulation of another morbific influence of a definite kind—namely, alcohol, or, perhaps more correctly, alcoholism, leaving on one side the questions of form and strength of the drink taken and its purity.

The direct effects of alcohol on the heart and vessels are by no means so easily determined as those of tobacco. In the first place they are complicated with the many indirect effects which it produces on these organs by deranging the functions of alimentation and assimilation, the nervous system and the kidneys, and with the secondary effects on the vessels and heart of chronic nephritis due to the same cause. In the second place, as we saw in my first lecture, alcoholism is very commonly associated with nervous strain, with gout and goutiness, with tobacco, with syphilis, and not uncommonly with two or more or all of these together. Eliminating as far as possible these sources of error by careful selection of cases, I find that the alcoholic heart presents clinical characters as a whole very different from those of tobacco-heart which we have just studied. The most striking and important of these are the evidences of actual pathological change in the size of the heart and the condition of the myocardium. We found no evidence that tobacco causes serious cardiac enlargement. Of 28 cases of alcoholic heart, on the other hand, which I examined clinically in connexion with the present inquiry (the average age being 46 years), only two hearts were of ordinary size, and, as a matter of fact, both of these patients were under 40 years of age. This result is in accord with my pathological observations. For instance, I have followed the condition of the heart carefully in an intemperate man, aged 43 years, and post mortem have found the heart to weigh 17 ounces, to be universally dilated in all its chambers, and to present enlargement of the mitral opening without valvular lesion, corresponding with a weak apex systolic murmur heard during life. These results are also in accord with those in Dr. R. Maguire's cases of acute dilatation of the heart from alcoholism, which he recorded as long ago as 1888,[3] and one of which occurred in a man, aged 23 years. Dr. F. W. Mott has found fatty degeneration of the myocardium in patients dying suddenly during alcoholism. With hardly an exception the præcordial impulse is weak—indeed, it is often imperceptible; the sounds are small and feeble and may be almost inaudible; in 20 per cent. of my cases a weak apex systolic murmur could be heard, varying with posture and from day to day, significant no doubt of leakage through a dilated mitral opening. The alcoholic heart is irregular and accelerated in about half the cases. The pulse tension is usually low; in one-third of the instances the radial artery was sclerosed; in one-fifth of them there was slight albuminuria; the legs may be œdematous. The complaints with which the patient comes to us are commonly of palpitation of the heart, faintness or actual faints, and præcordial pain; but it is very interesting to observe that angina pectoris is rare in the alcoholic as compared with the tobacco-heart in the ratio of from 4 to 15 per cent.

It is unnecessary for me to attempt to give you a sketch even in outline of the subject of either acute or subacute or chronic alcoholism. I would rather mention a form of acute alcoholic failure of the heart of which I have recently seen a case but which appears to be rare. A middle-aged woman at the end of each of her repeated bouts of active alcoholism has violent sickness; prostration passes into collapse, and for 24 hours or more she lies flat on her back with all the phenomena of what may be called acute air hunger; she breathes loudly and deeply, at the rate of 36 per minute, with groaning expiration. The expression is alarmed, despairing, and imploring; the nose is pinched; the surface is livid and cold; the breath is cold; the pulse is practically imperceptible at the wrist; and yet the præcordial impulse is both strong and extensive. The condition is at once one of collapse and urgent dyspnœa, much as in one form of so-called diabetic coma; and it is further remarkable in that it may pass off quite suddenly after having lasted, as I have said, for many hours. It is difficult to resist the conclusion that in such a condition as this some product of alcohol present in the blood is the cause of the remarkable phenomena.

The course of alcoholic heart in older subjects gradually becomes affected by the appearance of cirrhosis of the liver, Bright's disease, neuritis, and possibly dementia; and the method of termination is very various, including ordinary cardiac failure with dropsy. Sudden death occasionally occurs.

GOUT.

Of the many instances of disorder and disease of the heart and arteries that I have met with in gouty subjects at or over 40 years of age I have made a careful study of 29 taken from my private case-books. Twelve of these patients (10 males and two females) had suffered from ordinary articular gout; the other seventeen (six males and 11 females) had irregular gout as defined in my first lecture. The average age was 62 years. In no instance was there albuminuria. The physical condition of the heart and arteries and the complaints of the patients were remarkably alike in the two groups. In 23 out of the 29 cases the heart proved to be enlarged either on one or on both sides. In less than half the number the cardiac action was feeble; in a small number the impulse was entirely imperceptible; the heart-rate and pulse-rate were ordinary; the rhythm was but seldom irregular. It is a very remarkable fact that in no fewer than 12 out of the 29 cases of gouty heart a systolic murmur was to be heard over the aortic area, the manubrium and the right carotid, significant of disease either of the aortic arch or of the aortic valves—in every instance independently of rheumatism or other obvious cause than gout. This result is an interesting confirmation of the pathological observations of Dr. Norman Moore and Sir Dyce Duckworth, given by the latter,[4] and of the statement of Murchison[5] of his experience "that atheroma of the arteries at an unusually early period of life and diseases of the aortic valves which are not congenital and are independent of injury or rheumatism are met with far oftener in persons who are the subjects of the lithic acid dyscrasia or who have had gout than in those who have had no such tendencies." In seven (25 per cent.) of my cases a more or less developed systolic murmur was found in the mitral area, significant either of valvular atheroma and sclerosis or of leakage from ventricular dilatation. Very curiously, I have never met with aortic incompetence of gouty origin. When no murmur exists the cardiac sounds are commonly somewhat feeble and the second sound may be of ringing quality—this more commonly in goutiness than in developed gout. In agreement with this connexion the radial pulse is more often tense in the subjects of irregular than of regular gout; altogether high tension is found in more than one-half of the cases. The great majority presented distinct thickening of

[3] Transactions of the Clinical Society of London, vol. xx., p. 235.

[5] Clinical Lectures on Diseases of the Liver, third edition, 1885, p. 637.

the arterial walls. Besides a distressing feeling of irregularity, fluttering or intermittency, and dyspnœa on exertion, men who are the subjects of gouty heart complain most frequently of præcordial pain; women more often of palpitation and faintness or actual faints. In quite one-fourth of all cases of gouty heart the pain is anginal and such angina may be of the most pronounced type. A friend of my own, aged 60 years, began to suffer from gouty angina (diagnosed to be such by his family physician 40 years ago) at the age of 20 years. Almost every year, sometimes more frequently, for the last 12 years of his life he was liable to be seized with intense pain in the left side of his chest which rapidly extended to the neck and down the left arm with tingling in the hand, a sense of great constriction in the chest, faintness, and distress of breathing. He had immediately to rest, whereupon the distress subsided, but it did not perfectly disappear for hours. On different occasions, also in connexion with these anginal attacks, I have known him have free hæmoptysis, complete unconsciousness, vomiting, and sudden violent evacuation of the bowels. He also suffered from articular gout and irregular gout in almost every possible form.

OBESITY AND GLYCOSURIA.

Closely related to goutiness is a clinical type of disturbed metabolism, mainly characterised by corpulence, a bulky, flabby build, and glycosuria. Of this type, represented by 12 cases in my series, nine had glycosuria and two albuminuria; eight were men; the average age was 58 years. Only one had suffered from true articular gout. Here, again, the interesting observation was made that no less than three-fourths of the number had a systolic aortic murmur, none of them a regurgitant aortic murmur, and nearly one-half of them an ill-developed mitral systolic murmur. Thus, there appears to be more liability to atheroma in the gross, corpulent diabetic even than in the gouty man. In all the cases the heart appeared to be enlarged, but accurate physical examination is difficult or impossible in many of these subjects. The impulse was more often feeble than in the gouty, the cardiac sounds were equally weak, and the second aortic sound was occasionally accentuated. The pulse corresponded with the gouty pulse in thickness and tension, but it was more often found irregular and hurried. As for the complaints of corpulent and diabetic patients, they prove to be very similar to those of gouty individuals in respect of pain, but neither palpitation nor faintness was so often mentioned.

It must not be understood from what I have just said in my account of these cases that all disturbances of the heart in gouty subjects progress to valvular or vascular degeneration with associated cardiac enlargement and degeneration. The friend whose case I have just described at some length had led an active life, as I said, for 40 years; and, as I hope to show in my next lecture, the condition is amenable to treatment if this be based on a correct appreciation of the cause that is at work. But it is equally true that if correct advice be not given, or if it be given but be neglected, as happens so frequently, the endocardium and the aorta and other arteries steadily degenerate, chronic interstitial nephritis makes its appearance, and the patient dies either slowly from cardiac failure or suddenly from cerebral hæmorrhage.

CARDIAC STRAIN.

I will now proceed to consider the clinical characters of a class of cases in which you, Sir, will be particularly interested—strain of the heart in middle and advanced life. To make this part of my subject more plain I will discuss in the first place acute strain of the heart as it occurs after the fortieth year; afterwards I will consider the condition of the heart and arteries at this age in persons who have strained them in youth or early manhod. A man, aged 65 years, who came to me complaining of his heart, gave the following account of the commencement of his trouble. Four years previously on making a very hard stroke at golf he was suddenly seized with a sensation of something having happened in his heart. He played up to the next hole, but now felt the chest oppressed; he sat down and got relief. This experience was repeated, and he gave up the round. Walking home two miles he had to sit down occasionally with the same feeling. Ever since that occurrence exertion has produced the same effect. I found the ordinary physical signs of enlargement of both sides of the heart, a scarcely perceptible impulse, the cardiac sounds extremely feeble, the second being of a finely ringing quality; the pulse tense, quiet, and regular, but the radial artery by no means sclerosed. The patient's principal complaints were of irregular action of the heart which troubled him on lying down or when he was dyspeptic, and, as I have said, of post-sternal oppression on exertion. This man had neither albuminuria nor emphysema, but he had frequently suffered from ordinary articular gout. Belonging to this type of cardiac strain I have notes in all of 11 cases which I will briefly summarise. Eight were men and three were women, and their average age was 56 years. In all but one of them the heart was large, with feeble præcordial impulse; the sounds were small and feeble; the aortic diastolic sound was often ringing; in but one case was there a murmur—aortic systolic; with few exceptions the rhythm and the rate of the heart were ordinary. In half the cases the radial artery was sclerosed; in the majority the tension was not increased. Persons who strain their heart after middle life chiefly complain of præcordial oppression, a sense of palpitation and irregular action of the heart, and pain, which may amount to angina; and they may tell us that distress and disability in these different forms have troubled them for years. You will have observed that the man whose case I have read in particular was the subject of gout; and this brings me to the interesting fact that of these eleven individuals seven were gouty. We have already seen how greatly reduced is the resistance of the cardio-vascular system in gouty subjects, and are thus prepared for the readiness with which their hearts may be strained by exertion—a matter of obvious importance prophylactically. In other cases not included in this group the strain took the form of valvular injury, or it affected hearts already the seats of old-standing valvular lesions of rheumatic origin, but the present is not the occasion to discuss these. Nor need I add that a not infrequent result of acute strain of the aged heart, whether its valves have been already damaged or its myocardium badly nourished, is sudden death.

Now, I can understand that some of you, like Professor Allbutt, our earliest and highest authority on this subject,[6] might object to this application of the term "strain" to the effect of exertion in senile hearts. You might say with great reason that exertion in these subjects is not a cause of strain or dilatation of the heart but simply a test, as it were, or the proof, of cardiac debility and disability. But when we come to consider cardiac strain a little more closely it may be maintained just as easily that every dilated heart, every dilated cardiac chamber, every dilated blood-vessel has been strained. Whether, on the one hand, valvular disease, Bright's disease, or emphysema, or, on the other hand, myocardial degeneration, has disturbed that cardinal condition of a normal circulation *that the driving power must always exceed the resistance ahead*, over-distension and dilatation of the cavities, with excessive stretching of their walls, constitute or consist in mechanical strain. However, laying aside theoretical discussions of this character, the great practical fact remains that when the aged or ill-nourished heart is over-distended from sudden and severe exertion it acts at a mechanical disadvantage, and that as often as this may occur the heart suffers more or less in its efficiency; whilst, on the other hand, in confirmation of this consideration, the heart sometimes diminishes in size and præcordial distress disappears under strict treatment continued for a sufficient length of time.

STRAIN BEFORE THE AGE OF 40 YEARS.

A more interesting group of cases than those which I have just discussed is composed of persons who have strained their hearts in youth or early manhood, have never been quite well since, and in middle or advanced life are at last driven to us for help. Cases of this character would furnish excellent material from which we might attempt to judge of the after-effects of excess or abuse of muscular exercise in the young. This is a tempting subject of discussion, but far too long and much too important to be taken up casually at this time. Therefore I will content myself with submitting to you as plainly as I can certain facts bearing on it that have come before me in my present inquiry along with a few simple observations of a practical bearing. First, then, let me read to you the history of what I should call a typical case of the kind. A man, aged 69 years, complains that as often as he walks any distance or climbs a stair he is arrested by a distressing

[6] Clifford Allbutt: System of Medicine, v., p. 843.

sense of having a bar across the lower end of the sternum, breathlessness, irregular palpitation of the heart, and a very little choking in the throat. The discomfort has lately deserved the name of pain His heart is very large, the area of præcordial dulness being increased in all directions, and measuring transversely seven inches. The impulse is weak over the left ventricle but definite in the epigastrium; the sounds come in couples, moderately good and very weak respectively, without murmur; and the radial artery is large and thick, with rather low pressure and irregular rhythm. It turns out that for the last 40 years these uncomfortable feelings have troubled this man more or less and that at three different periods of his life—at the ages of 31, 42, and 67 years—they increased so much as to incapacitate him for many months—the first time with a sudden sense of something snapping in the heart, the second time with a faint, and always, as he believes, consequent on overwork. Now this man never had rheumatism or gout or syphilis, and was always a temperate, careful liver; and he volunteers the statement that he first felt his heart at Cambridge where he was captain of his college boat and was tried for the university boat, but felt himself that he was not fit for it. Belonging to this type of cardiac strain I have selected 11 cases. The heart is always found to be enlarged, and in about one-half of the cases it is irregular. It may be weak and beating at the ordinary rate, but in other instances it is increased both in force and frequency. Only in quite exceptional cases did I meet with endocardial murmurs in this group of old strained hearts; as a rule, the sounds were ordinary, with a disposition to accentuation of the aortic second sound. High tension and sclerosis of the radial artery were respectively found in about one-half of the cases. The patients complain most commonly of a distressing sense of irregular palpitation of the heart, and very commonly of præcordial pain, but rarely of angina. Faintness, also, is sometimes mentioned. Let me hasten to add with respect to these cases that they do not include any instances of direct injury of the valves mechanically. Rupture or stretching of the aortic and mitral valves during exertion furnishes us with some very remarkable clinical cases; but it is with parietal strain that we are concerned now, physical over-stretching of the cardiac walls. The subjects of dilatation of the heart from mechanical stress suffer by no means from what is commonly called "heart disease" excepting in the worst cases, but yet they feel their hearts comparatively and it may be seriously disabled. Naturally they associate these feelings of disability with fresh attempts at exercise or exertion, as in the case which I have just read. As I pointed out in my first lecture, such exertion may not by any means be connected with the patient's occupation or daily duties, but quite often occurs during unwise attempts on his part to resume at 50 years of age the athletic exercises of his youth in order to reduce his weight, relieve his liver, or dispel gout. It is not wonderful that under such circumstances a permanently enlarged and badly-nourished heart should become embarrassed or even seriously deranged or still further strained. I have known a man, aged 43 years, going straight from London to the Alps, to have not only præcordial distress but dropsy of his legs after his first ascent in his regular holiday. Indeed, the man who has reached later middle-life with his heart enlarged by years of great bodily activity in youth, and settles down quietly on retirement, let us say, from the navy, sometimes finds that ordinary exercise is sufficient to produce alarming cardiac distress and curious loss of courage, obviously due to the muscular tissue of the thickened cardiac walls having fallen quite out of condition. How instructive, for instance, is the following case. A man, aged 60 years, who has led from his boyhood upwards a life of physical activity and at the same time of temperance, and has suffered from neither syphilis nor rheumatism, but possibly from a doubtful attack of gout, settles in a relaxing provincial town, continues to eat heartily, and considers that a little work in the garden is sufficient exercise for him. He increases in weight, his breath gets short, his heart flutters, and now he begins to get anxious about his health, fancying, as he says, that he has all sorts of diseases—a disposition to worry about himself which is entirely new and provoking to him I find his heart very large and feeble, the cardiac sounds scarcely audible, and in the mitral area a well-developed systolic murmur. The patient is ordered to reduce his diet as a whole and in respect of carbohydrates, to return carefully to walking exercise on the level, and to take a calomel purge followed by a saline twice a week and a mild strychnine mixture. He improves and continues to do so, is able to walk miles without discomfort, and in the course of two months not only do I find his heart reduced in size on physical examination, but I fail to hear the apical murmur, which must have been produced by dilatation of the left ventricle. The bearing of such a case as this on the pathology, prevention, and treatment of certain cases of senile heart disease will be obvious to all. We must be careful, however, to observe that neither unwise abandonment of wholesome exercise nor ill-advised return to physical exertion, separately or in succession, can be regarded as the only cause of the recrudescence of cardiac distress after 40 years of age in those who have strained their circulation in youth. Any one of the many circumstances that produce cardiac failure and dropsy in chronic valvular disease may lead to embarrassment and fresh dilatation of the simply enlarged heart: anæmia and chronic disease, the acute specific fevers, including pneumonia, emphysema, granular kidney, gout, syphilis, tobacco and alcohol poisoning, as well as anxiety and worry, and in women the advent of the menopause. In these cases of old cardiac strain, as in every form of chronic valvular disease and of chronic heart disease of all kinds, not only the original and permanent lesion but the recent and probably temporary circumstances that caused the failure have to be ascertained and fully respected in connexion with prognosis and treatment.

SYPHILIS.

Syphilis appears to account for a very considerable proportion of the more serious cases of heart disease which we meet with in older subjects, of course excluding chronic valvular disease originating remotely in endocarditis; but I ought to repeat here what I have already mentioned, that syphilis as a cause of cardio-vascular lesions is very often associated with other morbific influences, particularly strain and alcohol. Of its position as the principal cause of serious disease of the valves as distinguished from the walls of the heart originating in middle life there can be no question. No fewer than nine out of 28 patients of whose cases I have private notes were the subjects of double aortic disease; practically all the others had a loud ringing second sound over the aorta, significant of degeneration; pain of anginal type in half the cases was the prominent complaint; and two-thirds of the subjects had sclerosis of the radial artery. When we consider that syphilis does also affect the myocardium primarily, that fibroid disease, chronic aneurysm and fatty degeneration of the heart are all traceable to specific disease of the coronaries in many instances, and finally, that many of the subjects of syphilitic cardio-vascular disease have perished before the age of 40 years, the magnitude of this cause can be fully realised. I believe that the profession in general have not yet woke up, if I may say so, to the gravity of this subject. How seldom we inquire for a history of specific disease in patients coming to us with cardiac disease in middle life. To no one, as far as my reading goes, are we so much indebted for the truth on this subject as to my friend and colleague Dr. Mott. 13 years ago he published a paper on 21 cases of sudden death from cardio-vascular disease, and in nine of these there was a history of either actual or probable syphilis. What was of greater interest, however, at that early date, he drew attention to the association of syphilitic cardio-vascular lesions with Bright's disease in the broad acceptation of the term. Dr. Mott's work in the interval on syphilitic lesions of the arterial system of the brain has been so brilliant and is so generally known, that it requires nothing more than this appreciative mention by me; and it saves me the trouble of an excursion into the large subjects of cerebral hæmorrhage and thrombosis in connexion with these lectures.

NERVOUS STRAIN.

I confess that it is difficult to say much that is of real diagnostic value on the clinical aspect of cardio-vascular disorders and disease from nervous strain As I remarked in discussing this subject from the etiological point of view, several factors come into play besides nervous excitement followed by exhaustion and their effects on the heart, great vessels, and cerebral arteries; and the cases, therefore, are found to present a puzzling variety of features. Certain clinical characters are, however, common to the majority. Arterial tension is high; the radial artery is thick, sometimes markedly so; the heart

enlarges; and in about one-half of the cases a systolic murmur is to be heard either in the aortic or in the mitral area significant of chronic endocardial lesions. I have already pointed out that in some of these patients polyuria and temporary albuminuria occur along with the high tension and increased action of the heart; but later the heart may fail. The direct cardiac symptoms of which they complain are of the ordinary charac er, palpitation with accelerated cardiac frequency and pain—not angina—being the most common at first; feelings of indescribable discomfort and suffocation in the more advanced stage.

After having reviewed, as I have attempted to do, the principal clinical chara ters of the diseases of the heart in middle and advanced life under their several causes, it may appear for a moment strange that the most important of all the clinical types of cardio-vascular degeneration has been mentioned only incidentally. This is chronic Bright's disease, which, from its complex pathological relations, its widespread effects on the heart and circulation and the organs that they supply, and the far greater gravity of these than those of any of the other causes which we have studied, unless it be syphilis, is a subject of endless interest to us all. Fortunately for me, my immediate predecessor in this chair on the medical side, our distinguished Fellow, Dr. Samuel West, took for his subject the Clinical Aspects of Granular Kidney, and thus relieved me of a task which he was so much better able to discharge than I am.

BLACKWATER FEVER.[1]

BY J. W. W. STEPHENS, M.D. CANTAB.

I PROPOSE as briefly as possible to set forward what I believe are established facts concerning blackwater fever and to leave out of consideration mere hypothesis; and the facts as to its relation to malaria are those which it has been the chief aim of most observers to determine. I shall also leave out of consideration evidence of this kind which is not supported by microscopical examinations of the blood. A microscopical examination is of the utmost importance, but I believe that we have facts in our knowledge now which justify us in saying that the conclusions drawn from such an examination have been too comprehensive, and that, in fact, it is not true to say that if microscopical examination shows no parasites in the blood therefore the case is not one of malaria.

In making examinations of the blood of Europeans supposed to be suffering from malarial fever and who had not taken quinine our diagnosis was not infrequently against malaria, as after repeated search we could find no parasites or pigment. But can we get malarial fever without parasites in the peripheral circulation? The following cases prove, I think, that we can.

CASE 1.—There were daily rises of temperature to about 100° F. Then after a few days there was a tertian rise. There was daily vomiting. It was only after prolonged examination for some days that a single ring-form parasite was found.

CASE 2.—There were well-marked subjective symptoms and daily rises of temperature to above 100° F. Several examinations of the blood were made before any quinine had been taken. After prolonged search no parasites were found. In a few days the temperature was normal. A leucocytic count now gave: large mononuclear, 24 per cent.; small mononuclear, 10 per cent.; and polymorphonuclear, 66 per cent. We felt certain now (*vide* below) that this was a case of malaria, and a re-examination of the blood taken before the exhibition of quinine now revealed, again after a long search, one parasite, confirming thus the diagnosis based entirely on the leucocytic count.

CASE 3.—The following is a case where clinically there was not the slightest doubt as to the malarial nature of the attack, but there was absolutely no proof objectively. On Oct. 28th, 1900, the evening temperature was 99·4° F., the patient feeling unwell. At 5 P.M on the 29th the temperature was 103°. There was much vomiting. An examination of the blood proved negative. Quinine (1·0 gramme) was administered, but it was mostly vomited. On the 30th, at 6 P.M., the temperature was 100° and the patient was vomiting continually. Examination of the blood again gave negative results. Quinine was administered hypodermically. The leucocytes when counted gave the following percentages:—

—	Oct. 29th, 5 P.M.	Oct. 30th, 8 A.M.	Oct. 30th, 6 P.M.
Large mononuclear	16·4	15·2	15·0
Small ,, ...	7·0	11·2	14·0
Polymorphonuclear ...	76·6	73·6	71·0

Other cases will be found in our report. Türk [2] also has noticed the same fact.[3] Celli [4] has lately published similar facts. He says that in first attacks parasites may be quite scanty and not infrequently completely absent in the circulation. Ziemann [5] finds that in the Cameroons the number of parasites in the circulation is often in no wise proportional to the gravity of the attack. Plehn has also noticed this in the Cameroons. Our own observations, then, establish the fact that malarial fever is not necessarily accompanied by parasites in the peripheral circulation, so that it does not follow because in a case of blackwater fever parasites are absent that it is necessarily non-malarial.

But now let us consider if there is any evidence of the existence of a malarial infection in blackwater fever, and first we must revert shortly to a consideration of what is the evidence of malarial infection in a supposed case of ordinary "fever." 1. If parasites are present it is good evidence that the case is malaria, though we must now bear in mind that the relation of the number of parasites to the severity of attack is not that absolute one that has been supposed. 2. Besides the exceptional cases recorded above which refer solely to those where no quinine had been taken we get a large class of cases where parasites are absent simply from the fact that the patient has taken or is taking more or less quinine. 3. In the absence of parasites we have still two means of proof left: (*a*) the presence of pigmented large mononuclear leucocytes; and (*b*) the relative change in the percentage of large mononuclear leucocytes. Of the first little need be said. It is only necessary to point out that the number of pigmented leucocytes may be extraordinarily small, so that it is only after an examination of all the leucocytes in an extensive sheet of blood spread on a slide that one or two are found, and again they may in undoubted malaria be absent. A negative examination here, again, is not absolutely conclusive against malaria.

The leucocytic change.—It had been previously known that in malaria the relative value of the large mononuclear leucocytes was often increased. We found that this increased ratio was often very marked up to from 20 to 30 per cent., and we were able to show that it bore an inverse relation to the tertian temperature curve, so that the curve of this increased ratio was almost an exact inversion of that of the temperature. During the pyrexia the value was normal or low, while during the apyretic periods the value was high. Whether the relative increase was a real one we were not then concerned to determine. But seeing that we had constantly this disturbed ratio bearing a definite relation to the temperature curve, its diagnostic importance seemed to us great, and, in fact, after a time a glance at a slide was sufficient to show whether or not this relative increase was present and we could deduce safely the existence of a malarial attack. It is not uncommon, then, in malaria, especially during the apyrexia, to have a large mononuclear value of even from 40 to 50 per cent. From a large number of counts of European bloods we have come to consider a value as high as 20 per cent. of the large mononuclear leucocytes as proof of a malarial infection. We may refer here to the case quoted above. In spite of long-continued search in this case previously to the taking of

TABLE TO SHOW THE OCCURRENCE OF MALARIAL INFECTION IN BLACKWATER FEVER.

No. of case.	Parasites.	Pigmented leucocytes.	Necropsy.	Percentage of large mononuclear leucocytes.	Percentage of small mononuclear leucocytes.	Percentage of polymorphonuclear leucocytes.	Proof of malarial infection at time.	Parasites present in peripheral blood.	Remarks.
2*	—	Pigmented leucocytes.	Much pigment.	22·7	14·6	60·7	Yes.	No.	—
3*	Numerous parasites.	" "	" "	55·9	—	43·0	"	Yes.	22/5/99. Before onset of blackwater fever.
		" "	—	19·3	—	80·0		No.	24/5/99. Shortly after onset.
4*	Three crescents.	" "	—	48 8	8·4	41·6	"	"	—
5*	—	—	—	30·6	7·8	61·6	"	"	—
6*	—	—	Much pigment.	—	—	—	"	—	Post-mortem examination only.
7*	—	—	" "	—	—	—	"	—	" "
8*	—	Pigmented leucocytes.	" "	12·0	7·0	80·0	"	No.	—
9	—	" "	—	23·6	6·0	68·6	"	"	—
10	—	" "	—	27·0	19·0	54·0	"	"	—
11	Parasites.	" "	—	21·5	16·4	61·0	"	Yes.	12/7/00. Case seen earlier than usual
		" "	—	11·5	12·0	75·0	"	No.	13/7/00. Blackwater fever still present
12	—	—	—	6·4	4·6	89·0	No.	"	Only a single blood examination made.
13	—	Pigmented leucocytes.		21·0	13·5	65·0	Yes.	"	—
14	—	—	[illegible]	23·0	23·0	54·0	"	"	—
15	—	—	—	24·0	13·6	61 5	"	"	—
16	—	Pigmented leucocytes.	—	12·7	10·5	77·0	"	"	6/10/00.
				15·5	10·5	74·0	"	"	7/10/00.
17	—	—	—	22·7	12·6	64·0	"	"	Convalescent, six days.

* NOTE.—See the First Report to the Malaria Committee. Case 1 is not included on account of the insufficiency of the examination.

quinine no parasites or pigment had been found. The temperature after some days reached normal; a leucocytic count was then made and 20 per cent. of large mononuclear were found. We felt quite certain now that this was a case of malaria, and consequently again examination was made of the original films, and now after prolonged search one, and only one, typical young ring was found. This increased mononuclear value was also found in the blood of native children infected with parasites but presenting none of the ordinary symptoms of malarial fever. It should be added, too, that in blackwater fever, as in malaria, there is often a well-marked leucopenia as low as 2000 per cubic millimetre.

To two subsidiary means of diagnosis—viz., the presence of pigmented leucocytes and the leucocytic change—we attach great importance, and, indeed, they may be the only means of diagnosis, except the clinical features, we have; if the patient is taking quinine, for one of the most striking effects of quinine even in small doses is to cause a disappearance, it may be complete, of parasites from the peripheral circulation, even though the fever does not necessarily abate. We can now consider what the evidence is of the existence of a malarial infection in blackwater fever. It should be also borne in mind that the patients had in all our cases already taken quinine in varying amount before the onset of blackwater fever (vide Table).

In only three out of 16 cases were parasites present. In Case 3 the parasites occurred in large numbers during the course of a typical malignant tertian; when blackwater fever supervened, after the giving of quinine, they then disappeared completely. In Case 11, which was seen earlier than usual, parasites were at first present, but they disappeared completely next day. In Case 4 a total of three crescents only was found. So that, excluding the case where parasites were present before the attack only, we have two out of 16 cases—12·5 per cent—showing parasites or, excluding the case with three crescents only, one out of 16—6·3 per cent. On the other hand, Koch [6] in his collected series of 41 cases finds parasites in 18—i.e., 43·9 per cent. If, however, we analyse this table we shall see that though the occurrence of parasites is far less than in Koch's cases, yet there exists evidence of a malarial infection in 93·7 per cent. of cases, for in Cases 2, 4 5 8, 9, 10, 13, and 16 at least one typical crowded pigmented leucocyte was found, and in several cases these bodies were common. In Cases 14, 15, and 17, although neither parasites nor pigmented leucocytes were seen, yet the number of large mononuclear leucocytes was in every case over 20 per cent., a percentage which we believe to be strong evidence of a malarial infection. But we have further evidence of a somewhat different kind. It has been stated by A. Plehn [7] and by F. Plehn [8]—and a knowledge of their excellent contributions to the subject is indispensable for everybody who would consider the question—that if before the onset of the attack of blackwater fever the blood of a patient be examined parasites will always be found, and, in fact, an examination of such published cases—and they are necessarily very few, for unfortunately blood examinations are often entirely neglected—shows that this is so, and so far I have not been able in the published cases to find an exception to this, provided, of course, that those cases are not considered where the patient has already taken quinine. But I can readily believe that exceptions may be found, as I have already shown that typical malaria (without quinine) may exist without parasites in the peripheral blood. Thus, to give examples of this condition. Plehn.—Case A.—4/1/90: fever; scanty parasites. 5/1/90: quinine, 1·0 gramme; two hours later blackwater fever; no parasites. Case B.—4/3/90: occasional parasites. 5/3/90: morning, quinine, 1·0 gramme; 12 noon, blackwater fever. 6/3/90: no parasites. Koch.—Case 12.—Before the onset of blackwater fever tertiana simplex duplicata with sporulating forms; 0·75 gramme of quinine given; blackwater fever; disappearance of parasites. This case is peculiar in that three weeks previously during an attack of blackwater fever malignant tertian parasites were present, but in the peripheral blood there were no parasites of tertiana simplex. Ziemann.[9]—A case of malaria; parasites present; 1·0 gramme quinine; blackwater fever. Stephens and Christophers.[10] Case 3.—22/5/99: typical malaria; numerous parasites; quinine, 1·8 grammes, hypodermically. 23/5/99: parasites very scanty; 12.30 noon 0·6 gramme quinine. 24/5/99: 11 30 A.M., blackwater fever; parasites absent.

[10] Reports to the Malaria Committee of the Royal Society, First and Fourth Series (London: Harrison an Sons).

Again, a consideration of those cases where parasites are found during the attack makes it clear that, as a rule, they disappear very rapidly, and so constantly is this the case that one is led to suspect that there is some other chemiotactic factor (possibly the hæmoglobinæmia) at work besides the quinine in producing this. These cases, then, show that if a patient's blood is examined before the attack of blackwater fever and before the taking of quinine parasites will generally be found in the blood—that is to say, that the evidence, where procurable, shows that the initial illness of which a history is present is malarial, and we cannot lightly pass over these facts and fail to note that when the blackwater fever has supervened the evidence from existence of parasites is much less—in Koch's collected cases, for instance, 23 out of 41; in our own only two out of 16.

We have further again evidence of another class of cases—viz., those where no parasites were found during the attack of blackwater fever, yet they have reappeared later under conditions which exclude the possibility of re-infection, as in Europe; in fact, a relapse of malaria has occurred after the blackwater fever. Numerous examples of this might be quoted. We have already incidentally mentioned Case 12 in Koch's series, where three weeks after an attack of blackwater fever (parasites = tertiana maligna) a relapse of tertiana simplex occurred. Of the existence of this infection there had not been previously the slightest evidence. Koch.—Case 10.—Patient in East Africa, blackwater fever, no parasites; in Germany, many relapses, tertian parasites. Ollwig.[11]—16/7/98: patient in Germany; fever; quinine; blackwater; no parasites. 31/7/98: parasites; malaria tropica. Stephens and Christophers.[12]—Case 4.—8/7/99: blackwater fever. 9/7/99: crescent. 10/7/99: quinine; blackwater fever; no parasites; left hospital 22nd. 29/7/99: typical malaria; numerous parasites.

Let us now consider the post-mortem evidence. It has been argued that the finding of pigment post mortem means little in a resident in the tropics—that everybody might show this condition. Not only is this not so, but, on the contrary, Koch, in two post-mortem cases of blackwater fever in patients who had had many attacks of fever, records the complete absence of pigment in the organs, and we have also examined the organs of a patient long resident in malarial regions without finding a trace of pigment. It is necessary, however, in describing the existence of pigment to notice its amount and distribution, particularly as to its occurrence in the endothelial cells and the leucocytes of the tissues, e.g., spleen, for from this we can estimate the relation of the pigment to the actual attack. While in two of our collected cases we have not complete evidence on this latter point, yet in three post-mortem examinations made by us the evidence of very recent malaria was conclusive. It is important to note that one case in which before the blackwater fever there were numerous parasites, but afterwards none, showed post mortem in the spleen, not rings, but numerous parasites closely resembling developing gametes. Thin,[13] also, has recorded two cases where sporulating parasites were found in the brain post mortem with only a scanty development of pigment in the organs. With reference to Koch's two cases where pigment was absent it should be noted that death occurred on the ninth and fourth day of the disease respectively, possibly intervals long enough to allow of the disappearance of pigment resulting from mild attacks. We have, then, the following data with regard to the presence of pigment:—

Author.	Case.	Pigment.	Remarks.
Koch	1-2	Negative.	No parasites, no pigment.
Thin	3	Yes.	Pigment very scanty in spleen; sporulating parasites in brain.
F Plehn	4-16	Yes.	In all malarial pigment in organs, but sometimes very little.
Stephens and Christophers	17-21	Yes.	In all pigment in abundance.

This shows the presence of pigment in 19 out of 21—i.e., 90·4 per cent.

Bearing in mind our first conclusion that the absence of parasites did not necessarily exclude malaria, we have actual evidence of the existence of a malarial infection brought from these five points of view: (1) existence of parasites during the attack; (2) pigment and mononuclear percentage increase; (3) parasites before the attack; (4) parasites after the attack; and (5) the post-mortem evidence. To us it seems that this cumulative evidence is irresistibly strong. It is, perhaps, necessary to meet here an objection which has been raised of a similar nature to that brought against the post-mortem evidence—viz., that in any series of Europeans in the tropics taken at random would be found similar evidence of malaria. This supposition again is not supported by the facts, for of 44 Europeans examined among communities especially liable to malarial fever parasites were found with the greatest rareness and pigmented leucocytes not more frequently. Thus out of 44 cases only two showed parasites (crescents) and only two pigmented leucocytes—i.e., less than 10 per cent.—whilst if we include those patients who showed even a slight mononuclear increase the percentage still only reaches 20. For the complete details on these and other points we must refer to our reports to the Royal Society.

We regard, then, the evidence based on an analysis of our own cases as proving the existence of a malarial infection. If we consider also the evidence of a slightly different nature which we have brought forward we regard the conclusion that blackwater fever is essentially a malarial process as irresistible—that is to say, that blackwater fever can rarely, if ever, occur except in a person who is suffering from, or has quite recently suffered from, a malarial attack.

There still remains another side to the question—viz., is quinine the immediate cause of an attack of blackwater fever? Those who have so hastily criticised Koch and who attribute to Koch opinions not to be found in his writings do not appear to be acquainted with the fact that it was 40 years ago that Tomaselli[14] in Sicily published his first case of quinine intoxication in malaria, that F. Plehn and A. Plehn in the Cameroons have published a total of over 80 cases of blackwater fever, and that these observers had, before Koch worked on malaria, arrived at the conclusion that in the vast majority of cases quinine was the determining cause. Very exceptionally they allowed that the action of quinine could be excluded, and Koch has also virtually admitted this, suggesting that insolation even may be responsible for an attack.

There is little to be added to the question. Anyone who has read Tomaselli's, Plehn's and Koch's cases can surely have no doubt that quinine is the immediate cause of blackwater fever. In none of our cases could we exclude its action and the interval between the administration of quinine and the onset of hæmoglobinuria was very constant—i.e., from four to 10 hours. We, moreover, had one case in hospital (Case 4) in which quinine appeared definitely to induce a severe attack of hæmoglobinuria. It must be admitted, however, that it can be induced by other causes than quinine, for occasionally cases—e.g., by Plehn—are recorded in which it is positively stated that no quinine was taken. While not doubting this, we would point out how unreliable the statements of patients are, and we have notes of many cases in which the statements of patients on this point are directly opposed to the facts. Secondly, it is recorded among natives, who presumably do not take quinine. The authority of observers such as Plehn makes us accept the statement. We failed ourselves to find a case among natives; it was quite easy, however, to procure cases of so-called blackwater fever, but these were due to bilharzia hæmatobia. The state of things may perhaps be best illustrated by the analogy of hæmatoporphyrinuria. It is agreed that here sulphonal is the commonest cause, yet among those taking sulphonal it is a rare disease; on the other hand, it is not denied that hæmatoporphyrinuria also occurs among those who have not taken sulphonal.

It is worth recording here a series of observations we made on the isotonic point of the blood in malaria and blackwater fever. We found that in patients suffering more or less frequently from malaria the isotonic value is constantly raised, while in blackwater fever we found a value below that of normal blood. This low value, it is said, also occurs after loss of blood from various causes. In African natives also we found not uncommonly an isotonic value lower than that observed in any European. The difference was as great as 0·04–0·06 per cent. salt. It is possible that the raised isotonic value

[11] Ein Beitrag zur Behandlung der Malaria mit Methylenblau, Zeitschrift für Hygiene, Band xxxi., 1899, p. 317.

[12] Loc. cit.

[13] Brit. Med. Jour., 1899.

[14] La Intossicazione Chinica è l'Infezione Malarica.

in malaria may give some indication of the extent to which the corpuscles of the patient have been subjected to an injurious influence and so give some indication of those cases of malaria in which it would be dangerous to give quinine. It is interesting to note in this connexion that if to a dog a quantity of toluene-diamin be administered insufficient to produce hæmoglobinuria, yet we have in these cases a raised isotonic point—i.e., a lowered resistance of blood cell (Lapicque et Vast[15]).

Another factor that is of some use as an index of danger is the presence of albuminuria or a high-coloured urine. The colour in these cases is not due to bile pigment, but may be due to urobilin.

To conclude, blackwater fever is essentially a malarial infection in which quinine is the most common immediate determining cause of intoxication. Protection from malaria will insure protection from blackwater fever. Complete protection from malaria may, as my own two years' experience in tropical Africa under all kinds of conditions shows, be attained without the taking of any quinine, by paying scrupulous attention to clothing and the use of the mosquito net.

THREE CASES OF ACUTE DIFFUSE SEPTIC PERITONITIS RESULTING FROM APPENDICITIS; OPERATION; RECOVERY.

BY W. G. RICHARDSON, M.B. DURH., F.R.C.S. ENG.,
ASSISTANT SURGEON, ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

CASE 1.—A lad, aged 13 years, was on Jan. 6th, 1900, getting ready at 1.45 P.M. to go into Newcastle with his mother, when he felt a little pain in his abdomen, low down on the right side. He spoke of it at the time, but, thinking that it was ordinary stomach-ache, he put on his coat and caught the 2 o'clock train at Heaton. Whilst shopping in town the pain became steadily worse and he had to walk about holding on to his mother's arm. Eventually he could bear it no longer and he was taken to the station, where he sat waiting for a train to go home. His mother then noticed that he was very ill. On arriving at Heaton at 4 o'clock he became much worse and was doubled up with pain, and whilst walking with great difficulty up the inclined way out of the station he vomited. After getting home he became feverish and was put to bed. At 10.45 he had a rigor and vomited again. At 1.30 A.M. on the 7th he was seen by Dr. A. Livingston who prescribed for him, and he slept until 7 o'clock, when he woke up feeling rather better but in a burning heat and the pain was still there. At 10 o'clock he was seen by Dr. F. Russell who found him delirious. During the afternoon he again had a rigor and he vomited twice. Heat was applied to the abdomen and gave some relief, but he still wandered in his talk. When I saw him with Dr. Russell (at 10 P.M.) he looked very ill, with pinched features, high temperature, rapid pulse, and dry tongue. His abdomen was slightly distended, rigid, and extremely tender all over. Dr. Russell agreed with me that his condition was due to general peritonitis and that the only useful treatment was an operation. As there was neither accommodation nor preparation for such treatment in his home, the boy was wrapped up in the bedclothes in which he lay and was at once taken in a cab to a private hospital. At 1 A.M., on the 8th—i.e., 35 hours from the onset of the illness—assisted by Dr. Russell, I operated by the method introduced by Mr. J. Rutherford Morison, making a long oblique incision from the outer edge of the right rectus abdominis upwards, outwards, and backwards into the loin. The abdominal cavity was full of milky pus and, after the excess had poured out of the wound, the appendix was found lying with its tip in the pelvis. There were no adhesions and the appendix was perforated. It was removed and the abdominal cavity was mopped out with gauze until all the pus appeared to have been cleared away. Gauze wrung out of normal saline solution was then put in as a drain; one piece in the pelvis, one amongst the small intestines, and one up to the liver. All the loose ends of gauze were brought out together at the hinder end of the wound. The wound was then sewn up in layers with catgut and a dressing was applied which was changed every four hours. The after history was uneventful and the boy is now perfectly well.

CASE 2.—A youth, aged 17 years, was at work on the morning of May 23rd, 1900, but he felt weary and complained of a little pain in the lower half of the abdomen. He went home and took his midday meal as usual and then lay down on a couch. Whilst so lying he felt a sudden acute pain in the abdomen, but did not vomit. His mother applied hot fomentations and gave him a dose of castor oil which acted freely, and he felt easier. (It appears that he had had two similar attacks—one two years before and the second a year afterwards—that both had been treated in the same way, and that each had passed off in a few hours.) He had a good night and in the morning he felt better, but he complained of feeling "sore across his belly." He got up, dressed, and lay on the couch. At 1.30 P.M. he jumped up suddenly and screamed with a violent pain in the abdomen. He then turned faint and vomited. He was seen for the first time by Dr. W. L. Ruxton at 3 o'clock, and at 4 o'clock I saw him in consultation. He was then very ill, with an anxious expression, a fast pulse, a slightly raised temperature, and a dry tongue. He appeared to be in great pain and his abdomen was very tender, hard, and slightly distended. He was taken at once in a cab to a private hospital where I operated at 7 P.M.—i.e., about 30 hours after the acute onset of illness—by the same method as was employed in Case 1. There was such a large quantity of similar milky pus that I turned him on to his side and allowed the pus to run out. His appendix, which was perforated and non-adherent, was removed, the abdomen was mopped out with gauze, and three gauze drains were left in—one under the liver, one in the pelvis, and one amongst the coils of small intestine—the ends of all emerging from the hinder end of the flank incision. During the two following days the patient was very ill and the abdomen became gradually distended with flatus. On the morning of the 27th he became unconscious, and I thought that he was dying. No flatus had passed for 48 hours. The tongue was dry, the teeth were covered with sordes, and the pulse was becoming weaker and steadily quicker. As no flatus came through an ordinary rectal tube I passed a Kelly's long sigmoid speculum, and a little flatus and watery fæces came away. By repeating this many times I got away what in the aggregate amounted to a large evacuation. The tube was passed every half-hour during the morning and afternoon, when, to my surprise, the pulse began to fall and the patient improved slowly through the night. He regained consciousness, made an excellent recovery, and is now in perfect health. I had never previously seen anyone who was so ill with acute septic general peritonitis recover.

CASE 3.—A married woman, aged 35 years, was on Nov. 13th, 1900, shopping all day in a town 10 miles distant from her home. On her return in the evening she did not feel well, and during the night she woke out of her sleep with great pain all over her abdomen. Having had similar attacks, which she had been told were due to appendicitis, on two previous occasions—the first in June, 1899, and the second six months later, during each of which she was laid up in bed for a few days—she thought that this illness arose from the same cause, and she sent for Dr. F. Hunton, of Sedgefield, who saw her on the morning of the 14th. Dr. Hunton found her with raised temperature, fast pulse, rigid but not distended abdomen, and marked tenderness in the right iliac region. During the morning she vomited. A purgative was administered and hot fomentations were applied. She continued to feel ill during the whole of the 14th, but the pain subsided somewhat towards night. Her bowels were moved and she vomited during the evening. At 1 A.M. on the 15th—i.e., nearly 24 hours after the initial attack—she was suddenly seized with excruciating pain in the abdomen, vomited immediately, and became very ill and collapsed. Early in the morning, when seen by Dr. Hunton, she was much worse than on the previous day. Morphia gave some relief. Early in the afternoon she was again seen and it was then noticed that her abdomen was beginning to swell. At 7 P.M. I saw her with Dr. Hunton. She was then looking very ill; she had pinched features, a dry tongue, and a feeble voice. Her pulse was rapid and hard. Her abdomen was moderately distended and the right iliac region was excessively tender, so much so that I could not make out whether or not there

[15] Comptes Rendus Hebdomadaires de la Société de Biologie, May, 1899, p. 369.

was a lump It was clear, however, that she was suffering from acute peritonitis, that her intestines were beginning to distend, and that if she could not be relieved she was likely to die. Believing that the source of the peritonitis was a rupture of the appendix we decided to operate at once, which I did by the same method as in Case 1 and Case 2. The appendix was found to be perforated and there was a great quantity of thin and milky pus amongst the small intestines, in the pelvis, and up under the liver. I removed the appendix, mopped up the pus with gauze until the peritoneum appeared to be clean, and then placed one gauze drain in the pelvis, another under the liver, and a third amongst the small intestines, bringing them all out at the after end of the flank incision. The following morning the temperature was 99° F., and the pulse was 100 and of good character. Slight sickness and hiccough, with some abdominal distension, were present. The gauze was removed on the fifth day. The patient made a good recovery and is now in excellent health.

These three cases are strikingly similar and are typical of the "fulminating" form of acute appendicitis which is the most fatal of all varieties. In the initial stages they were not distinguishable from ordinary cases of appendicitis in which recovery could take place either by resolution of the inflammatory process or by limitation of the disease to the formation of an abscess; yet in the more advanced stage, and without warning, the life of each patient was placed in immediate danger and death could only be averted by immediate operation, performed with the minimum amount of preparation which could be desired. In each of these cases there was a premonitory stage, lasting for a few hours, during which the patient felt unwell and uneasy in the abdomen. This was followed by the sudden development of acute symptoms which subsided somewhat after several hours of severe pain. This lull was followed in about 24 hours from the initial acute attack by strikingly violent and sudden increase of all symptoms and in seven or eight hours more the abdomen was found to be full of pus. In each case the appendix was seen at the operation to be acutely inflamed without any surrounding adhesions and to have a gangrenous perforation through its walls

The interpretation which I put on these symptoms is as follows. The appendix being strictured, or an enterolith becoming impacted fluid collected and distended the appendix, causing uneasiness—appendicular colic. This, I believe, might pass away and give no further trouble, but the tension in the appendix increased and then the pain, owing to the stretching of the peritoneal coat, became very great—the initial attack. The contents being septic, and no relief of tension having taken place, the appendix became acutely inflamed and the pain was aggravated—the period of local pain and of feverish symptoms. As the inflammatory process advanced the walls of the appendix gradually softened and lost their power of keeping up tension—the lull, during which the patient felt less pain, in fact, was "rather better." The relief was similar to that experienced when an inflamed lymphatic gland goes on to suppuration, for in such a case the pain becomes less when the capsule of the gland softens and stretches. After this period of relieved tension the peritoneal coat of the appendix gave way at one or more points, possibly where the gangrenous process had been accelerated by the pressure of an enterolith, and the septic contents escaped—the acute exacerbation of pain and vomiting. The entire process was so rapid that no adhesions had time to form, and from this stage onwards the symptoms of acute appendicitis became lost in the much graver symptoms of acute general septic peritonitis.

If, as I believe, the above is a true picture of the pathological process as revealed by the symptoms in these "fulminating" cases, then it may be possible to formulate some rule which will enable us to recognise them and to operate before such a catastrophe as general septic peritonitis supervenes; for the process differs only from the course of events in ordinary cases, which terminate by resolution or in the formation of an abscess, in the virulence and rapidity of the process and in such changes as are due to that rapidity. The difference is one of degree but not of kind. I do not wish to advocate operating in all cases of acute appendicitis; on the contrary, I believe that it is a fact, which is borne out by the experience of every medical man who is engaged in general practice to whom I have spoken, that for one case which requires operative treatment there are many which do well without operation. Not only many medical men but nearly every layman has been shocked by the death of some patient or acquaintance from peritonitis within two or three days of his being seen in perfect health. These cases are almost without exception examples of peritonitis following fulminating appendicitis; and although they represent only a small percentage of the total number of cases of appendicitis they actually amount to a great number. On Nov. 16th, 1900, I saw a man, aged 38 years, with the following history. He was at work all day on the 14th. During the evening, being then in his usual health, he went to the water-closet, but returned to the house looking ill and complaining of pain in his abdomen. The pain continued all night and he vomited. He was ill all the next day. Early in the morning of the 16th the pain became much worse and he vomited; he looked very ill and his abdomen commenced to swell. At 6.15 P.M. I saw him in consultation. He was lying on his right side with his legs drawn up. His abdomen was greatly distended and was dull in the right half; it was very tender, especially in the right iliac region, where there was a lump as big as a fist—so tender that the man cried out when it was touched although he was then dying. His medical man told me that this was the third similar case in his practice in a fortnight where the patients had died and all of them had died within 48 hours of the onset of symptoms.

In cases where adhesions are formed and an abscess develops there is not the same immediate necessity for operation as in these acute cases, where prompt action must be taken because a very few hours' delay may result in the death of the patient; therefore it is of the utmost importance to be able to recognise these urgent cases before perforation of the appendix occurs. The rule which I follow is this. If the patient is seen within a few hours of the onset of the illness hot fomentations are applied to the abdomen. Morphia is only given in cases of urgent need. I then wait and see what progress is made. If there is steady improvement waiting is persevered in as long as this continues. By "improvement" I mean improvement in *all* the symptoms. It is not enough that pain and tenderness should be less, for the period during which the pain diminishes may be the very time in which an operation should be performed. All the symptoms should subside together: the temperature should fall, the pulse should become less frequent, local pain and tenderness should grow less, and the patient should look better. The last is an uncertain quantity but a very important one. The chief points are a diminution of the local tenderness and lessened rigidity of the muscles, but these must not be taken as a certain guide when the patient continues to be otherwise ill. In illustration of this I may mention a case which I saw on May 2nd, 1899, with Dr. George R. Murray and Dr. W. T. Hall, at Whitburn. The patient was a little girl suffering from a first attack which began the day before. The local pain and tenderness had much improved, but the child still looked flushed and ill, and had a foul tongue and raised pulse and temperature. We decided to operate at once because we thought that the greater risk lay in leaving her alone. The appendix was found to be lying across the pelvis with its tip near the brim of the left side. There were no adhesions whatever, and the peritoneal coat of the appendix was bright scarlet, whilst, on opening it, the mucous and muscular coats were seen to be completely gangrenous. We all felt sure that this was a case in which general peritonitis would have followed sloughing of the entire appendix, as the inflammatory process was advancing so rapidly that there was no reasonable prospect of localisation by adhesions. This child—assuming my previous explanation to be the correct one—was operated on during the period of ease in which the peritoneal coat of the appendix had softened and relaxed sufficiently to reduce the tension and with it the local pain and tenderness, but the improvement in local symptoms was no indication of subsidence of the disease.

If such a rule be followed—namely, to remove the appendix in very acute cases which at the end of 24 hours do not improve in *all* the symptoms—a large number of lives will be saved which are often, perhaps usually, lost through the operation being performed after perforation has taken place. At the same time, it is obvious that by applying such a rule a number of cases will be operated on in which, although the appendix is on the point of giving way, it is yet guarded by adhesions. Against this must be placed the risk of waiting and the possibility of abscess formation, and above all the simplicity and safety of operating at this stage must be taken into account. This, however, must not be made an excuse for a

hard and fast rule of treatment that all cases of acute appendicitis must be operated on. Surely that is not sound surgery. If the appendix has perforated and general peritonitis has become established it is then a matter of supreme importance to operate without any unnecessary delay — unless the abdomen is distended with flatulent intestines or the hands are cold and red, when it is best not to operate at all, as there is evident general vascular and nerve failure and any operation could only hasten death.

In the first few hours of acute general peritonitis the distension is not due to gas in the intestines, but to a collection of thin milky-looking pus in the general peritoneal cavity; whereas in the later stages there is little or no fluid and the distension is due to gas in the intestines, which are then dark-coloured, dry, and sticky, with adherent lymph on the peritoneal surfaces, suggesting that the wall of the intestine has played the part of a sieve, allowing the fluid to pass through but retaining the solid portion of the pus as a covering of lymph.

The method of draining the peritoneal cavity with gauze appears to me to be preferable to that by drainage through a tube. When the coils of the intestines are lying in close apposition it does not seem to be a hopeful way to drain with a tube which can only be efficient for a limited area. It seems difficult to drain the pelvis against gravity by means of a tube which can only do good by relieving tension and allowing the pus to empty freely from the upper end. On the other hand, by using gauze drains packed loosely amongst the intestines a very large area of the peritoneal cavity can be drained, and more than drained, for the gauze acts as a suction pump and will for days continue to empty the peritoneal cavity as a wick will empty a bottle. It is not a painful operation to withdraw such gauze if it be left in for five days. The attempt to do this on the second or third day gives great pain, but later the meshes of the gauze are filled up by lymph which makes its surface smooth and slippery and its removal easy.

Newcastle-on-Tyne.

RESECTION OF THE SUPERIOR CERVICAL GANGLION OF THE SYMPATHETIC FOR GLAUCOMA AND ITS RESULTS.

BY H. WORK DODD, F.R.C.S. ENG.,

OPHTHALMIC SURGEON TO, AND CLINICAL LECTURER ON OPHTHALMIC MEDICINE AND SURGERY AT, THE ROYAL FREE HOSPITAL; SURGEON TO THE ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, ETC.

IT may be seen on reference to a contribution by me on this operation which appeared in THE LANCET of Oct. 13th, 1900, p. 1071, in which I described my first case, how I there advanced the opinion that "if such an operation does permanently and satisfactorily arrest the glaucoma, preserve the sight, relieve the pains, and restore the patient to even comparative comfort, then I consider it may be undertaken." I may at once say that the later results of this, my first case, as also those of my second case, which I here briefly describe, are not so favourable as to lead me to regard the removal of the superior cervical ganglion of the sympathetic as successful in the cure of chronic glaucoma. It may, perhaps, be repeated here that these operations were based upon the work of Dr. Jonnesco of Bucharest.

My second case was that of a fairly well-nourished country woman, aged 44 years, unmarried. She was admitted into the Royal Free Hospital under my care on Oct. 16th, 1900, suffering from chronic glaucoma in both eyes. The disease commenced about two years before this date, when she began to have pain in the left eye which was operated upon in January, 1900. After the operation the eye was better for a while, but gave trouble again about three months later, and at this time the right eye also became painful. Both eyes were operated on in June, 1900, and the left one again in the following September. The pain and other symptoms not having lessened since this last operation, Dr. E. E. Maddox of Bournemouth, under whose excellent care she had been, thinking her a suitable subject for the bilateral removal of the superior cervical ganglions of the sympathetic, kindly sent her up to me for this operation, he having been interested in my previous case. When 20 years of age, that is about 24 years ago, the patient had cataracts removed from both eyes. Her general health had always been good.

On admission, in the right eye there was a large coloboma from iridectomy in the upper part of the iris which otherwise appeared to be fairly normal and free. There was no lens and the edge of the remaining capsule could be seen. The tension was about + 2. The field of vision was considerably and irregularly contracted. The disc was cupped and the fundus showed other signs of chronic glaucoma. The vision = $\frac{1}{60}$ c + 11 D = $\frac{6}{18}$. The patient complained of constant pain, varying in intensity, in the eye and head. In the left eye there was a large operative coloboma upwards, the iris being otherwise practically normal. The lens was absent and the pupil area showed some remains of capsule. There was also a very little pericorneal injection. The tension was about + 3. The vision was reduced to perception of light only. The disc was cupped and there were other indications of glaucoma in the fundus. The patient had a considerable amount of pain, more or less constant, in this eye, which also was somewhat tender.

In my former case I removed the two superior cervical ganglions at one sitting, but I found this to be a somewhat heavy and trying experience for the patient. Wishing also to notice the effect of the unilateral operation I determined in this case to remove the ganglions at different times. Accordingly, on Oct. 19th I removed the superior cervical ganglion of the left side. The operation chosen was that described by Dr. Jonnesco under the name of "pre-mastoid" which has been previously fully reported in my communication alluded to above and therefore need not be repeated here. Immediately after the resection of the left ganglion the tension of the eye became a soft normal. On the next morning there was slight ptosis, the eyeball appeared to be a little sunken in the orbit, and the tension remained a soft normal. There was also a little injection of the conjunctiva. On the 22nd the tension was still low. There was some alteration in the voice, which sounded somewhat gruffer than usual, and it hurt the patient to talk. She protruded her tongue with difficulty. There was no excessive amount of mucus in the pharynx. She did not complain of any pain in the neck or head on that side. There had been no pain in the eye since the operation. On the 26th the wound was practically healed and the patient sat up for a short time. On Nov. 1st the patient felt very well, the wound was quite healed, and there was no pain in the eye. The tension remained soft. On the 5th the same operation was repeated on the right side of the neck, with like results as to tension, ptosis, &c. The stitches were removed on the 12th, and on the 15th the wound was quite healed, the case having done uninterruptedly well since the operation. On this day there was no pain in the right eye and the tension was a soft normal. On the 16th the patient complained of some pain over the right eye during the previous night. The tension in the right eye was normal, but that in the left eye gave a faint suspicion of being slightly raised. On the 19th the tension was normal in both eyes. There was no pain in either eye nor in the head. The ptosis had practically disappeared. The field of vision of the right eye was considerably increased, and the vision itself had improved from $\frac{1}{60}$ to $\frac{6}{60}$ without glasses, c + 11 D sph. = $\frac{6}{18}$. The patient was discharged on the next day.

The method of operating at intervals on the two sides of the neck appears to be a more satisfactory procedure than that of removing the two ganglions at one time.

Dr. Maddox, about Christmas time, kindly reported by letter that the tension had returned and that he found it necessary to employ pilocarpine drops. On Feb. 18th, 1901, Dr. Maddox wrote to say that the tension was then + 2. The eyes then have returned to the same state as they were in before the operations for the removal of the ganglions were performed. Therefore, though in this case the immediate effects were extremely favourable for a few days, the permanent result of the operations for the cure of the glaucoma is *nil*. Inasmuch as this patient had no lenses she was thought to be a suitable subject for this operation. The possibility of the glaucoma resulting from cicatricial changes was naturally also considered.

I also here give the final results of my former case.[1] It can be seen on reference to the details that in that case also the immediate effects were distinctly satisfactory. It is

[1] THE LANCET, Oct. 13th, 1900, p. 1071.

now about seven months since the operations were performed. The vision of the patient is exactly what it was before I removed the ganglions and the tension is about +1 which is about the same as formerly. The pupils, however, which became contracted at the operations, remain so, and are active to light and to accommodation. The patient thinks that the pains in the eyes and head are in no way lessened. In the region of the scar on the right side of the neck she frequently has a moderate amount of pain which seems to run "into the throat and up into the back of the head." She herself does not consider that she has derived any benefit from the operations I therefore again express my opinion that from the results obtained from these two cases the removal of the superior cervical ganglion of the sympathetic system does not cure chronic glaucoma.

The central origin of chronic glaucoma may be a fact, but if it be so, the removal of the superior cervical ganglion apparently does not interrupt the connexion with the eye Either the connexion is not by this route or some other means of communication are established very soon after the resection of the ganglion. These cases seem rather to point to chronic glaucoma being a peripheral trouble.

Harley-street, W.

THE ELIMINATION OF ARSENIC THROUGH THE HAIR AND ITS RELATION TO ARSENICAL POISONING.

BY EDMUND KNECHT, PH.D., F.I.C.,
CHIEF OF THE CHEMICAL DEPARTMENT, MANCHESTER MUNICIPAL TECHNICAL SCHOOL;
AND
W. F. DEARDEN, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H. VICT.,
CERTIFYING FACTORY SURGEON, HARPURHEY DISTRICT OF MANCHESTER.

THE differentiation of arsenical peripheral neuritis from ordinary alcoholic peripheral neuritis has been hitherto purely a clinical one, though it must, of course, be granted that when Dr. E. S. Reynolds made his alarming discovery of the prevalence of the arsenical form in beer-drinkers the necessary confirmation was provided by the detection of arsenic in the beer which those people had been in the habit of drinking. Such confirmation, whilst undoubtedly of great value, could not, however, be universally applied as an aid to diagnosis, and a method of detecting with certainty the arsenical causation in any particular case has naturally to be sought in another direction. The ability to detect the specific bacterial causation of certain diseases has made a wonderful difference in the accuracy with which such complaints can be diagnosed, so that, from analogy, we would naturally conclude that the ability to separate from the body and estimate with certainty the specific agent in the causation of arsenical peripheral neuritis would prove of immense value. The difficulties, however, surrounding investigation with this object in view have up to the present been insuperable. It is well known that arsenic is rapidly eliminated from the system *viâ* the kidneys and can be readily detected in the urine, but this test can only apply to cases where the ingestion of the contaminated material has been recent. The deposition of arsenic in organs such as the liver can be left out of the question, at any rate during the life-time of a patient. Again, the predilection of arsenic for the skin and its appendages is common knowledge and Mr. W. Kirkby has gone so far as to confirm a diagnosis of arsenical neuritis by the detection of the noxious element in a scab from the patient's body. Scales are but rarely met with in cases of this character, but there are very few patients who do not possess some amount of hair upon the body. As a quantity of hair sufficient for analysis can easily be removed and taken away for investigation, it certainly does appear strange that such should not have been better made use of as a medium of universal efficacy for showing that arsenic has been present in the system. Dr. Dixon Mann in his work on forensic medicine simply notes the fact that arsenic has been detected in the hair, but no English writer appears to have gone further into this phase of the subject. The likely explanation of this is to be found in the difficulty of estimating arsenic in the hair by the ordinary methods.

As having a direct bearing upon this question, it is well to draw attention to an article in the *Comptes Rendus* of August 6th, 1900, by Armand Gautier of Paris. This observer takes an important and extended view of the part played by arsenic in the animal organism and makes special reference to the function normally exercised by hair as a means of eliminating this element from the system. He does not, however, deal with the question from a pathological point of view, nor does he state any quantities except in the case of the thyroid gland and the blood. If Gautier's construction respecting this special eliminating function be correct, it might reasonably be expected that the hair of people taking an abnormal amount of this drug for any length of time would contain the element in an increased and appreciable amount. That such is the case is beyond doubt.

Samples of hair taken from six people (males) were submitted to analysis. Two samples were from well-marked cases of arsenical beer poisoning, another from a patient who had been taking one-ninth of a grain of arsenic per diem for an extended period, and three from healthy individuals, aged respectively 16, 23, and 35 years. In the three last-named samples arsenic was found to be present, but in quantities too minute to be estimated in one gramme of substance. The sample from the patient who was taking the drug medicinally was found to contain arsenic in the proportion of 0·3 in 10,000. One of the two patients who were the subjects of arsenical beer poisoning had present in his hair arsenic to the extent of 0·3 in 10,000, whilst the other showed the much larger proportion of 1 in 10,000. The vast difference in the proportion found in these samples to that in the three healthy samples shows in a marked manner the value of chemical analysis of the hair from a diagnostic point of view.

The estimation of arsenic in the hair may also prove to be of immense value from a medico-legal point of view—viz., in the post-mortem examination of cases of chronic arsenical poisoning, and particularly in exhumed bodies, since hair is one of the last parts of the body to undergo organic decomposition.

The method employed in the estimation of arsenic in the samples referred to above was Sanger's modification of the Marsh test. To preclude the possibility of any of the arsenic being overlooked by reason of its being present in the hair in organic combination the weighed samples (one gramme) were in each case first dissolved in fuming nitric acid (specific gravity, 1·5), and after boiling in this until the violent evolution of nitrous fumes had subsided the solution was transferred to a glass tube which was carefully sealed and heated for two hours to 250° C. The tubes were then opened with the usual precautions and the solution was evaporated to dryness to expel all nitric acid and then transferred to the Marsh apparatus. At least two estimations were carried out in each case.

A SHORT ACCOUNT OF A FATAL CASE OF LARYNGEAL DIPHTHERIA COMPLICATING MEASLES.

BY GEORGE J. MAGUIRE, M.B., B.CH. R.U.I.

THE interesting cases recorded in THE LANCET of Feb. 2nd (p. 321) and 23rd (p. 549), 1901, where these two diseases were synchronously manifested, give rise in one's mind to some doubt as to whether the rarity of this particular mixed infection is not apparent rather than real, and due more to the paucity of published notes than to the scarcity of clinical material. The following short account of a case that impressed me very strongly at the time, and of which many of the details remain vividly in my mind, may prove not to be uninteresting.

In the spring of 1898, during an epidemic of measles in the district of Paddington, I saw an infant, aged about 18 months, who was covered with a typical exanthem and had all the typical symptoms of morbilli. The other children of the family, and of the two other families occupying the different floors of the house, were in various stages of recovery from the disease. As the infection seemed to be pursuing an ordinary course no medical advice was sought. In the early morning of the day on which I

visited the child, however, some difficulty in breathing had suddenly arisen and was gradually increasing, so that the mother became alarmed and sent to the surgery. When I saw the infant it was suffering from the most intense inspiratory dyspnœa, all the muscles of respiration, ordinary and extraordinary, being in violent action, air being drawn into the lungs only by the strongest efforts and a loud crowing noise accompanying every breath. The child was somewhat cyanosed and evidently in terrible distress. The possibility of membranous obstruction, probably diphtheritic, at once suggested itself; but on careful examination of the pharynx not a vestige of membrane was anywhere to be seen. The mother was most positive in her assurances that neither the patient nor any other member of the family had had sore-throats and that there was no diphtheria in the house, though in the same street a few houses away there were one or two cases. I saw the child again in the afternoon and evening, and at the fourth visit, as the remedies, medicinal and otherwise, that were ordered had brought about no alleviation of the symptoms, and as the condition of the child was gradually and steadily becoming more serious, I sent it to St. Mary's Hospital for tracheotomy. The operation was at once performed, and successfully, but the patient never rallied, dying some few hours afterwards. I communicated later with the hospital authorities, and learned that the operation had afforded much relief, but that the child was too collapsed for it to be of much avail. It was further stated—what is in view of the subject the most interesting fact—that the cause of the condition was very uncertain, and it was not till the necropsy that it was cleared up. It was then found that the larynx was almost occluded by a thick, tough membrane, clinically that of diphtheria, and proving on bacteriological examination to be diphtheritic. There had been no definite objective sign, nor was it possible to diagnose the case till the necropsy.

Had there been no post-mortem examination in this case it would have escaped recognition and a focus of infection would not have been notified to the local health authorities. It is highly probable that many cases of diphtheria go unnotified, either because of the mildness of the symptoms, subjective and objective, or from some concomitant masking of them.

Richmond, Surrey.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

WASTED QUININE PILLS.

BY JOHN CURNOW, M.D., F.R.C.P. LOND.

A PATIENT suffering from enteric fever, after 22 days of pyrexia of a very intermittent type and obstinate constipation, was treated on Feb. 4th with five grains of quinine in the form of two pills three times a day. On the 11th, after a simple enema, the pills were found in the stool. They were seven in number, hard, and apparently unacted upon by the gastric or intestinal juices. Enemata had been given on the 4th, 6th, 8th, and 10th, as well as on the 11th. It was subsequently ascertained that in making the pills water had been used instead of the glycerine ordered in the Pharmacopœia. The pills were not coated.

Wimpole-street, W.

A CASE OF HYDROPNEUMOTHORAX.

BY EDWARD FRAZER, L.R.C.P., L.R.C.S. IREL.

THE history of the following case and the treatment adopted may be of some interest.

On Jan. 1st I was called to see a girl, aged 22 years, who had been complaining of illness for five days previously. I found her quite delirious; her pulse was 140 and very feeble, her temperature was 103·8° F., and her respirations were 44 per minute. On examination she presented all the symptoms and physical signs of left pleural effusion with considerable displacement of the heart. The respiratory murmur over the left apex was absent and on percussion there was a distinct tympanitic note to the lower border of the third rib. The condition of the patient demanded immediate interference, so I at once decided upon aspiration and removed over two pints of a greenish, cloudy fluid, with numerous small flakes of lymph floating in it. The patient was put on a suitable diet and was given a mixture of iodide of potassium with cinchona. The removal of the fluid had no effect on the apical note. I again saw the patient on the 4th and found that the delirium had passed off. Her respirations were now 32, her temperature was 102·5°, and her pulse was 134. There was a considerable amount of fluid in the chest. On the 6th I removed one and a half pints of fluid similar to the first in appearance. The apical note was still unchanged. On the 11th I found the fluid was increasing, and on the 17th I again removed over a pint of a darker and more cloudy fluid, leaving almost as much more in the pleura. It had now become evident that the air at the apex must be got rid of in some way or otherwise the patient would not recover. Accordingly, I procured a small hollow needle, and having fitted it to the indiarubber tube of the aspirator I placed the patient on her knees and chest, when the air, with a never-to-be-forgotten gurgling sound, rushed to the back of the chest. The patient, unfortunately, could not remain in this attitude, and on resuming the dorsal position the air immediately returned to the apex. I then passed the needle into the chest along the upper border of the third rib and in an upward direction and removed a considerable quantity of air. The patient experienced instant relief. I then firmly strapped the chest. On the 30th I removed the strapping and aspirated half a pint of fluid somewhat clearer than on the third occasion. The after treatment consisted of iodide of potassium with tonics, small blisters, and a good sustaining diet. The patient is now convalescing and there is only a trace of fluid left. How the air got into the pleural cavity remains a question. There was no injury and no trace of phthisis. The result of the case seems fully to justify the treatment adopted.

Riverstown, co. Sligo.

NOTE ON A CASE OF ENTERIC FEVER WITH SEVERE HÆMORRHAGE FROM THE SIGMOID FLEXURE.

BY STEPHEN G. LONGWORTH, L.R.C.P. IREL.,
ASSISTANT MEDICAL OFFICER TO THE SUFFOLK COUNTY ASYLUM.

AN imbecile patient, a female, aged 26 years, in the Suffolk County Asylum, sickened on Nov. 2nd, 1900. The nature of her illness during the first week was very indefinite and was regarded as being probably nothing more than constipation. Her temperature, which was 101° F. on the first day, fell gradually and reached almost to normal on the fifth day. Her bowels, which had been confined for three days prior to the commencement of her illness, were opened by means of simple enemata. On the evening of the fifth day her temperature again commenced to rise, reaching 101° on the evening of the seventh day. She had some diarrhœa on the seventh and eighth days, but for the three following days she passed ordinary-formed motions. On the evening of the ninth day the temperature again commenced to rise and it continued to do so for the four following days. There was generally a rise of about 1·5° each evening and a fall of about one degree each morning. The temperature reached 103·4° on the evening of the thirteenth day, diarrhœa again supervened, and rose spots appeared for the first time. On the morning of the fourteenth day the patient suddenly became collapsed and her temperature fell by 3·5°. This was followed in the course of half an hour by the passage of at least a pint of dark red blood-clot per rectum. By the evening she had rallied, and for the next few days the temperature ranged between 101° and 102·5°. There was also constipation. (It should be said that the patient was taking opium.) Examination of the blood on the fourteenth day gave a positive reaction to Widal's test and the urine showed a marked diazo reaction. During the afternoon of the seventeenth day her temperature again fell suddenly from 102·4° to 96·8° and she became collapsed. This was followed almost immediately by the passage of about another pint of similar dark red blood-clot from the bowel. The patient never completely rallied from this hæmorrhage; although her temperature rose again to 102° on the

eighteenth day her pulse remained at about 140 and very thready in character. On the nineteenth day another recurrence of the hæmorrhage took place andon the day following she died.

At the post-mortem examination, which was made 12 hours after death, the condition of the small intestine was as follows. The mucous membrane of the ileum as a whole was pale; it presented about a dozen superficial ulcers which varied in size from one-eighth of an inch to one inch in diameter. The bases of the ulcers were clean and free from sloughs and showed no signs of hæmorrhage having taken place from them. As regards the large intestine, the sigmoid flexure, as viewed before opening, presented for about six inches in extent a purplish colouration, the peritoneum over it having its usual glistening surface. On opening up this portion it was found to contain a mass of dark red clot which was firmly adherent to the mucous membrane. On detaching this, which was done with some difficulty, the mucous membrane was seen to be quite free from ulceration, but there was a general thickening of the walls corresponding to the extent of the discolouration and due to a hæmorrhagic infiltration of the coats of the bowel. The remainder of the large intestine was quite normal. The spleen was much enlarged, congested, and weighed 340 grammes.

The above case ran a more than usually obscure and atypical course, but the point of special interest was the site from which the hæmorrhage took place. After having seen the pathological condition and on referring to the clinical notes of the case one might perhaps regard as a point of differentiation between hæmorrhage occurring from the usual site and hæmorrhage taking place much lower down in the bowel (as in this case), the fact that the passage of the blood per anum followed so soon on each occasion after the external manifestations pointing to internal hæmorrhage. Another point also in favour of this idea was that the blood-clots passed were on all occasions quite unmixed with fæcal matter. The only other case of which I can find any record in which possibly the post-mortem appearances might have been similar is one mentioned by Dr. Julius Dreschfeld.[1] He states that he has seen one case in which hæmorrhagic infiltration of the whole of the large intestine was found post mortem.

SALISBURY INFIRMARY.

A CASE OF PERITONEAL CYST SIMULATING OVARIAN CYST; LAPAROTOMY; RECOVERY.

(Under the care of Dr. GILBERT KEMPE.)

THE very rare condition described in the following case is somewhat difficult of explanation. Such a cyst might be derived either from the formation of extensive pleuritic adhesions or from the persistence and dilatation of some fœtal structure. The former hypothesis is in this case hardly tenable, and it is probable that the cyst was derived from some congenital abnormality, though it is difficult to say what the abnormality was. Occasionally urachal cysts (that is, cysts due to a dilatation of a urachus which was closed at both ends but not between) may attain large dimensions.

A married woman, aged 39 years, was admitted into the Salisbury Infirmary on Jan. 23rd, 1901, for progressive enlargement of the abdomen of about 12 months' duration. The patient, who had always been healthy, was the mother of four children, the last child being born four years ago. She got up on the fourth day after confinement and was very ill and had to return to bed again. There had been no miscarriages. The catamenia had been regular every four weeks, being normal in character and duration. The abdomen had been steadily enlarging for the last 12 months. This enlargement had been painless and the only trouble had been that of obstinate constipation. She had lost flesh lately.

On admission the patient was somewhat emaciated and had the characteristic facies. The abdomen presented the usual appearance of a large unilocular ovarian cyst. On the skin were many large scars which the patient said were the result of boils, from which she suffered about two years ago. Many of these scars were of the size of a shilling. The whole of the abdomen was occupied by a large tumour, the greatest circumference (42 inches) being just below the umbilicus. Midway between the umbilicus and the pubes a broad flat transverse band could be seen, which was resonant to light percussion and was evidently the transverse colon. On palpation the tumour fluctuated readily, and a fluid thrill could be felt over the whole of it. The tumour seemed to be fairly moveable and the abdominal wall appeared to move over it. The whole of the abdomen was dull to percussion, with the exception of the transverse colon above-mentioned and some slight resonance in the left hypochondrium and in the flanks. Per vaginam the uterus was drawn up almost out of reach but did not seem to be connected with the tumour. A slight sense of fluctuation was felt in the anterior fornix but none in the posterior. There was no evidence of any secondary deposit.

Laparotomy was performed on Jan. 25th. An incision was made in the middle line from the umbilicus to one and a half inches above the pubes. On opening the abdominal cavity the parietal peritoneum was found to be closely adherent to what appeared to be the cyst wall. An attempt to separate it failed. The cyst was then tapped with a glass cannula and 21 pints of fluid were drawn off. The fluid was dark green in colour and was sparkling with cholesterin crystals. A further attempt was then made to separate the cyst which again failed and the cyst was opened and explored from within. Both ovaries and tubes and part of the fundus uteri were found within it and were apparently healthy. Laterally the cyst extended into both flanks. Superiorly there was a large cul-de-sac extending to the posterior margin of the liver. The stomach and transverse colon could be identified in the anterior superior wall. No small intestines could be seen or felt. The kidneys and spleen could be felt behind the cyst wall. No attempt to remove the cyst wall seemed likely to be successful, so the wound was closed and a drain was inserted into the cyst at the lower angle of the wound. No dermoid structure was seen or felt.

The after-progress was satisfactory. The temperature never rose above 100°F. The drain was removed on the third day and the sutures were taken out on the tenth day. The walls of the cyst seemed to fall together quite easily. On Feb. 10th the wound was quite healed with the exception of a small granulating area where the drainage-tube had been. Palpation of the abdomen revealed nothing abnormal except around the abdominal incision, where there was a hard and seemingly solid tumour of about the size of half an orange, which was not tender and was freely moveable. This was considered to be the contracted cyst wall and showed no signs of refilling. On March 2nd the patient was discharged from the hospital quite well.

Remarks by Dr. KEMPE.—This case is reported on account of its rarity. Serum-containing pseudo-cysts of encysted peritonitis are not uncommon but it is, I think, rare for such a cyst to contain a fluid holding an abundance of cholesterin crystals in suspension. The mimicry between this cyst and an ovarian cyst was singularly complete. Four other medical men saw the case and concurred in the diagnosis and it was not until the ovaries and tubes were found within the cyst that the true state of affairs was made clear. The presence of the cholesterin is not easily explained; there was no bile in the fluid nor was any connexion with a dermoid cyst apparent. Perhaps it and the colour of the fluid resulted from some old hæmorrhage or inflammation. The glass cannula mentioned I invariably use for emptying ovarian cysts, &c. It consists simply of a plain glass tube with a rubber tube attached to carry away the fluid. A small opening is made in the cyst with a scalpel which is plugged with a finger until the glass tube is inserted; this can readily be made to fill the opening by holding it more or less obliquely to the surface of the cyst.

[1] Enteric Fever: Allbutt's System of Medicine.

It is easily cleaned, is not so complicated in use as any of the ovariotomy trocars sold, and fulfils every purpose for which it is wanted.

I am indebted to Mr. R. T. Richmond, house surgeon, for the notes of the case.

BIRMINGHAM GENERAL HOSPITAL.

A CASE OF DERMATITIS FOLLOWING ACUTE LICHEN PLANUS.

(Under the care of Dr. T. SYDNEY SHORT).

WITH regard to the following case of lichen planus the fact that the mother of the patient was also affected with the disease is of interest, for it is not usually considered to be hereditary in origin. The very extensive character of the rash is also noteworthy.

An anæmic young woman, aged 21 years, was first seen on Nov. 8th, 1900. She said that she first noticed an eruption which itched badly in June. It came out in small pimples with flat tops on the inner surface of the right arm near the wrist. She thought that they were heat lumps as they kept her awake at night on account of the itching they produced and the consequent scratching which ensued. Within a week a large number of pimples came out on the front and inner surface of the right thigh. Here the pimples soon formed patches and were terribly itchy. Somewhat rapidly they then broke out on her back and on the front and back of her chest, being especially abundant between the breasts; they also appeared on the calves of the legs, being accompanied in this position by much swelling. The worry and loss of sleep consequent on the continual itching had rendered her weak and ill so that she lost flesh and colour.

When seen the patient was covered practically all over the body, with the exception of the face, ears, hands and fingers, and toes, with a very characteristic lichen planus rash. Here and there were small areas of healthy skin in wavy lines along the arms and upper parts of the legs; but all the trunk, the legs below the knees, and even the backs of the feet, were completely covered. The rash consisted of the characteristic quadrangular flat-topped shiny papules in large closely-packed patches with outlying papules. They were covered with a fine scurfy scale which sparkled when viewed sideways in a strong light. The ankles and feet were very much swollen and both legs below the calves were covered with a thick purplish skin of the typical vinous hue, having a rough coarsely granular surface with much infiltration. Her legs ached so that she could scarcely stand. The right leg was worse than the left, the thick bluish hide extending upwards to the lower part of the thigh being extremely well marked on the inner side of the knee. The mucous membranes showed no sign of any eruption. It is noteworthy that the palms and soles were not affected in this case.

The patient was admitted into the Birmingham General Hospital under the care of Dr. Stacey Wilson, to whose courtesy Dr. Short was indebted for the opportunity of continuing the treatment of the case. This consisted of a warm bath with a good soaping all over, rapid drying, and then complete inunction with an ointment composed of equal parts of unguentum sulphuris and unguentum hydrargyri ammoniati put on in sufficiently large quantity to saturate the sheet in which she was closely rolled and kept. A considerable amount of dirty scaling took place during the first week. The papules gradually lost their shiny tops and the swelling of the legs diminished. The intense itching was relieved by the first thorough inunction and troubled her very little afterwards. She was kept closely rolled in the ointment-saturated sheets for five weeks, with a soap bath each week. She was then allowed to be up with sufficient ointment rubbed in to keep her underclothing greasy. On Jan. 10th, a week after her discharge, she showed no papules at all; the thickening of the skin of the legs had not quite disappeared, but the vinous hue had gone. The whole of the skin which had borne the eruption was stained with dark bronze-looking pigment, which was, she said, daily becoming fainter. Her general condition was greatly improved. No arsenic was given in this case, the only internal treatment being carbonate of ammonia and gentian as a tonic, nor was any soporific required, the external treatment being alone relied upon, and this cleared off the papules in six weeks.

Remarks by Dr. SHORT.—It is interesting that the mother of this patient has suffered from chronic lichen planus for 21 years. Hearing that she had a rash I sent for her and inspected a patch of well-marked lichen planus over the lower part of the back. She said that the rash first appeared six days after her daughter was born and had been present on and off since. She might be free from it for so long as two years at a time. It itched a good deal when it came out, but it did not trouble her much. When the itching was particularly annoying she had some treatment but not otherwise.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Lysigenic Action of Sera.—Observations on the Bactericidal Action of Blood.

A MEETING of this society was held on March 19th, Mr. W. WATSON CHEYNE, the President, being in the chair.

Dr. W. BULLOCH made a communication on the Lysigenic Action of Sera. After referring to the fundamental facts of the destruction of bacteria by serum he alluded to the experiments of Watson Cheyne, Fodor, Wyssokowicz, Nuttall, Behring, and Nissen, and pointed to the gradual evolution of the humoral theory of Buchner. R. Pfeiffer's work was next discussed and the experimental results which had led Pfeiffer to formulate the theory that in "antifectious" sera there were two distinct bodies—one in the immune serum itself possessing only slight inhibitory powers on the growth of the bacteria, but representing, as it were, the forerunner of the active bacteriolytic substances; the other produced in the body of the animal which had received the serum, and analogous or identical with alexin. By a combination of the inactive body with the alexin a specific bacteriolysis was induced. The experiments of Bordet, Ehrlich, and Morgenroth on hæmolysis were then discussed, and the close analogy of hæmolysis and bacteriolysis was emphasised. Dr. Bulloch then proceeded to detail the experiments performed by himself. They consisted in the injection of rabbits with the blood corpuscles of the ox. In the serum of such rabbits a hæmolysin made its appearance as the result of the injection. This hæmolysin was composed of two perfectly distinct substances which could be separated from each other. They were the intermediary or immune-body and the alexin ("addiment" or "complement" of Ehrlich and Morgenroth). By accurately titrating the immunised rabbit's serum he had been able to follow from day to day the course of the immunity and the amount of the hæmolysin. After every injection there was a profound fall in the hæmolytic dose, and this fall (which had been denied by Ehrlich and Morgenroth) was shown to be due to a diminution in the amount of the alexin. By a special method he had been able completely to separate the alexin dose from the immune-body dose, and charts were shown to demonstrate that there was no relation between these two factors. Further, the immune-body dose of the serum was found to be extraordinarily small (in one case $\frac{1}{20000}$ of a cubic centimetre accompanied by 0·2 cubic centimetre, which was the hæmolytic dose, of the serum by itself). By thus separating the two factors of the hæmolysis their relation to leucocytes could be easily demonstrated. Artificial leucocytosis was found to increase the amount of alexin without influencing the amount of the immune-body in the slightest degree. A complete chart was also shown exhibiting the minute changes during the first days of the immunisation against blood corpuscles. The relation of the experiments to bacteriolysis, and especially to R. Pfeiffer's work, was emphasised and the connexion with practical bacterio-therapeutics was pointed out. In order to ascertain what cells contained the alexin Dr. Bulloch produced artificial leucocytosis by sodium cinnamate, the white corpuscles going up from 10,000 to 28,000 per cubic millimetre. This had no influence on the immune-body, but the amount of alexin went up at once. The kind of animals used in experimentation was of great importance, for different animals differed enormously in their hæmolytic and bactericidal properties and in the elaboration

of the two substances referred to. The cause of congenital immunity was certainly connected with this question of alexin. He had attempted to produce an anti-complemental serum, but rabbits and guinea-pigs were not suitable animals for its manufacture.

Professor A. E WRIGHT communicated the results of an Investigation into the Bactericidal Action of the Blood, undertaken by Major W. B. Leishman, R.A.M.C., and himself. Professor Wright congratulated Dr. Bulloch on his survey of the recent work which had been done on the subject of immunity. He was not quite sure, however, that what was true of blood corpuscles held good as regards bacteria. It might be so, but it was a question which wanted to be investigated. He then described the technique which he had employed to test the bactericidal power of the blood. They had to work with extremely small quantities of blood. All the work that had been done hitherto had been qualitative only, but here the result aimed at a quantitative measure of the bactericidal power of blood under certain conditions. By the methods employed, which he described, almost absolute accuracy was obtained and the bactericidal power of the blood could be expressed quantitatively by the number of bacteria which could be killed by a definite quantity of blood. In normal conditions the bactericidal power of a person's blood varied very little from day to day. He had measured his own blood with typhoid bacilli and found it very constant. Experiments were made with various microbes. On staphylococci the blood had practically no effect and on streptococci it had not much more. On plague bacilli the blood had no bactericidal power. With typhoid and cholera bacilli the blood was very powerful. One cubic centimetre of blood would kill about 10,000,000 cholera bacilli, and after a dilution of about 20 the blood would still be able to kill off typhoid bacilli. Rabbit's blood had also been experimented with; this had enormous bactericidal power for cholera. A patient was referred to who had had for many years a constant succession of boils. He was inoculated with staphylococcus cultures. It was found that the inhibitory power of his blood on staphylococci was increased and he remained free from boils for three months. After inoculation there were three days during which the bactericidal power of the blood was diminished. After that time it went up. In conclusion, he (Professor Wright) thought that Dr. Bulloch had assumed too much in certain directions, but that his researches on hæmolysis were of great value.

Mr. W. C. C. PAKES remarked that it was a well-known fact, and one which he had often observed, that in an animal which had been inoculated with bacteria and after a lapse of time killed all attempts to regain the bacterium failed. Perhaps Professor Wright's experiments might throw some light on the explanation of this.

Dr. GEORGE DEAN complimented Dr. Bulloch on his communication. He (Dr. Dean) had taken great interest in the subject of hæmolysis and had performed several experiments confirmatory of the results of others. The alexin of diphtheria reached a high degree of immunity in certain animals. He had found that fresh serum added nothing to an immunised horse. The injection of certain kinds of serum which destroyed the hæmolytic power of the blood only destroyed it for a few minutes and it was regained in a few hours. This and other facts went to show that they could not always draw inferences from the hæmolytic to the bactericidal power of blood.

Dr. BULLOCH, in replying, remarked that a good deal of the older literature on the bactericidal power of blood would require to be revised, for the older methods were too coarse. The methods proposed by Professor Wright offered great promise of accuracy.

Dr. A. RUFFER (Cairo) exhibited Photographs of Kidneys and Ureters showing polypoid outgrowths due to the bilharzia hæmatobia.

CHELSEA CLINICAL SOCIETY.

Discussion on the Clinical and Pathological Relations of the Chronic Rheumatic and Rheumatoid Affections to Acute Rheumatism.

THE annual clinical debate of this society was held at the Jenner Institute of Preventive Medicine on March 12th, Dr. WILLIAM EWART, the President, being in the chair. The debate was opened by the reading of a paper by Dr. ARCHIBALD E. GARROD, which was printed in THE LANCET of March 16th, p. 774.

Dr. F J. POYNTON then delivered a joint communication by himself and Dr. ALEXANDER PAINE dealing with the infectivity of acute rheumatism with especial reference to the chronic types of the disease. They considered that the mean result of many years of experience had established acute rheumatism as a definite disease with definite peculiarities, and if that were granted it followed that if one micro-organism was constantly found to be present which when isolated produced identical lesions in animals then it was most probable that that organism was specific. In their experience acute rheumatism was probably the result of infection by one micro-organism. They held that pericarditis, pleurisy, and nodules were manifestations of the rheumatic affection and not superadded phenomena, so that to regard polyarthritis as the criterion of rheumatic fever and the other affections as complications was not in accord with present knowledge. Though salicylates were of great value in some cases of acute rheumatism there was no justification to consider them as tests of the rheumatic nature of the disease. The subsidence of the rheumatic process under the use of salicylates must have some meaning, but in their opinion a phase of rheumatism could not be claimed as a distinct disease. They thought that they had considerably weakened the position of those who considered acute virulent rheumatism as due to a mixed infection because organisms were not found in the simpler arthritic type by having demonstrated that the organisms in acute rheumatism were rapidly destroyed at the sites of the lesions and were therefore not easy to demonstrate in the tissues. They had isolated from 14 cases of rheumatic fever a diplococcus which grew in liquid media in streptococcal chains and on solid media in staphylococcal masses. Triboulet before, and Wasserman and Malkoff during the time they were working had also isolated a diplococcus from acute rheumatism. During the present year Fritz Meyer had published the results of a prolonged investigation of the bacteriology of rheumatic angina and had also isolated a diplococcus which in many respects, and especially in the experimental results which it produced, resembled the one they had described and with which they had obtained similar results. Their researches had been more detailed than those of others, and though different media had been used by various workers it seemed very probable that the organism in each case was the same. Though Meyer used a medium of high alkalescence and they used a faintly acid medium, in both instances the organisms grew well on blood agar which was only faintly alkaline. They had isolated the organism three times from the blood of patients suffering from rheumatic pericarditis, twice from the throat, four times from the pericardium, growing them also in the exudations, twice from the urine, three times from the cardiac valves, and once from the rheumatic nodule. The anatomy of the lesions they had produced in the rabbit was identical with that of those in man. For the inoculations all the cases that were chosen were undoubted cases of rheumatic fever and not a shadow of doubt as to their nature entered the minds of the physicians, who were Dr. W. B. Cheadle, Dr. D. B. Lees, Dr. F. G. Penrose, and Dr. A. E. Garrod. They had therefore concluded that the organism was a cause of rheumatic fever, for if they stripped that disease of valvulitis, polyarthritis, pericarditis, pleurisy, nodules, and chorea it was difficult to believe in its existence as there was then only left the constitutional tendency and not the disease itself. Though more researches were needed to prove the point they further believed that the organism was the only cause. If their observations were corroborated the pathology of rheumatic fever was in a firmer position than heretofore, and when once the toxins could be isolated they would be in a position to approach the explanation of the various lesions, both acute and chronic, with more confidence than they could at the present time. They had repeatedly demonstrated the diplococcus in the joint exudate in rabbits and had also found them in the joints in rheumatism. The organisms were rapidly taken up by endothelial cells and polynuclear leucocytes in those situations, and possibly this might account for the difficulty of demonstrating them in acute rheumatic arthritis, which was usually of less severe type than that produced experimentally in the rabbit. The presence of the organisms in that form of arthritis brought acute rheumatic affections of

joints into line with arthritis the result of septic gonorrhœal and pneumococcic infections. According to the researches of Dr. G. A. Bannatyne, Dr. A. S. Wohlmann, and Dr. F. R. Blaxall rheumatoid arthritis must be included in that group also. Gouty and syphilitic arthritis remained as examples in which no micro-organism had been demonstrated, the former perhaps not being the result of a microbic infection, the latter almost certainly being micro-organic. Another point to which they wished to call attention was the condition of the kidneys in acute rheumatism. In fatal cases they had found very definite changes in the parenchyma, especially of the convoluted tubules. There were marked cloudy swelling of the protoplasm of the renal cells and some desquamation. The change was diffuse, affecting a great number of the convoluted tubules. Further, they had isolated the diplococcus from the urine in acute rheumatic pericarditis. In rabbits, possibly because of their fur, the kidneys were more severely affected, but the changes were of the same type. There were much cloudy swelling and also some desquamation of the renal cells, and in their kidneys they had repeatedly demonstrated the micro-organisms. In the rabbit they had traced this condition step by step to the formation of a white infarct, which certainly in the rabbit and most probably in man was not the result of a gross embolism, but was the result of the invasion of a considerable number of the diplococci in the particular area, and as a result the cloudy swelling in that area passed over the limit to the stage of necrosis which accounted for the white appearance of the infarct. It appeared to them that the kidney was an important site for the elimination of the poisons produced by the rheumatic infection and that in that process the kidney itself to some extent suffered. Usually, the injury was not gross, for though albuminuria, and in some malignant cases hæmaturia and nephritis, occurred in this disease, as a rule there was not albuminuria or evidence of serious renal inflammation. When a white infarct healed they knew the result was a scar, and it was possible that repeated attacks of acute rheumatism might do permanent damage to the renal tubules, not of the gross nature found in the infarct, but of a grade sufficient in severity to destroy the functions of many tubules, leading perhaps to the gradual destruction of the renal cells and their replacement by fibrous tissue. Repeated attacks of acute rheumatism in the young might lead to fibrosis of the kidney in the adult or, short of that, might impair the kidney's function for the elimination of the rheumatic poison in later life. As a result of this it might be that a subsequent attack of rheumatism in adult life, though less severe because the adult was less susceptible, was more chronic, because the poisons were eliminated with more difficulty. When they considered gout they knew that the kidneys suffered much in that disease and that some authorities gave to the kidneys first place in its causation and all allowed that the impairment of their function was a prominent factor in the more chronic inveterate and cachectic type. For those reasons it seemed to them important to study the kidneys very closely in acute rheumatism, and perhaps it might be found that albuminuria was more frequent than was generally supposed or that the peculiar condition of cyclical albuminuria might sometimes be a result of the impairment rather than destruction of function that appeared to be the result of rheumatic fever. They had collected facts to show that some cases of malignant endocarditis were truly rheumatic and not the result of secondary infections. This suggested that some of those lesions of joints that run on to ulceration and destruction of cartilage were really rheumatic. The disease had altered in type and for some reason had become locally malignant in those situations as it sometimes became in the valves. This, they pointed out, was no new suggestion, but was commented upon in the classical work upon pathology by Wilks and Moxon.

Mr. N. C. MACNAMARA said with reference to the toxic origin of rheumatoid arthritis that it was evident that some of the chemical substances produced by specific micro-organisms led to rapid destruction of tissues, such as was witnessed in pyæmia; others took years to run their course, such as leprosy; and there was a class of cases such as those known as "gonorrhœal rheumatism" which in point of time ran an intermediate course. There could be no question as to the toxic nature of this last form of disease, or as to the fact that the gonococci were present in the structures implicated in cases of gonorrhœal arthritis, which was an affection not far removed from chronic rheumatoid arthritis. Dr. Todd had many years ago dwelt on the connexion that existed between certain instances of chronic arthritis and leucorrhœa. He believed that the absorption of unhealthy secretions from the uterus led to symptoms of rheumatism, and ultimately to the ankylosed and deformed joints characteristic of chronic rheumatoid arthritis. In the year 1835 Mr. Macnamara met with a case in which a woman, 25 years of age, presented typically deformed and fixed joints, which he, like Dr. Todd, attributed to the absorption of septic matter, not from the uterus, but from the sockets of teeth extensively affected with dental caries. From that time onwards he had watched cases in which the only curative treatment for symptoms of chronic rheumatoid arthritis that could be relied on was the removal of the cause of septic infection. He fully recognised the fact that the symptoms and pathological changes characteristic of this form of arthritis were attributable in some cases to rheumatism, in others to gout, or it may be to a neurosis, but some of these cases unquestionably depended on toxic poisoning, and any form of rational treatment must be based on the appreciation of the origin of the disease with the object of its removal and of overcoming its deleterious influence.

Dr. C. O. HAWTHORNE, in discussing the relation of acute rheumatism to chronic rheumatoid arthritis, said they were all agreed in calling the acute disease characterised by general febrile disturbance and pain and swelling affecting several or many joints "acute rheumatism." They were all further agreed that subacute rheumatism was possibly of essentially the same nature as the condition called "rheumatic fever." It was admitted that there was a condition, chronic in its course for the most part, marked by swelling and deformity in many joints, usually called "chronic rheumatoid arthritis." To the question, Was chronic rheumatoid arthritis simply a chronic form of the disease known as rheumatic fever or was it an entirely different disease? some authorities said that it was simply rheumatism, others stated that whatever it might prove to be it was certainly not a rheumatic arthritis. There was the theory that chronic rheumatoid arthritis was a disease dependent upon micro-organisms, and there was the theory that the condition was due to septic absorption. Another theory was that the phenomena of rheumatoid arthritis depended upon disturbances in the trophic nervous apparatus, some of these being primary changes in the spinal cord, others being induced in the spinal cord by irritation reflected from the pelvic organs or from some other viscera. A not inconsiderable number of cases of chronic rheumatoid arthritis were found in patients who had at some previous period in their life suffered from rheumatic attacks. There were instances in which the chronic rheumatoid condition followed immediately upon an attack of acute rheumatic fever. If the family histories of these patients were examined there were not infrequently found evidences of rheumatism in members of the family immediately related to the patient. There were certain cases in which the symptoms, the history, and the physical signs and conditions were such that it was impossible to exercise any confident judgment and to say that that was a case of rheumatism and not rheumatoid arthritis. Dr. Hawthorne then proceeded to give in detail the history of a case in point and exhibited photographs illustrating the condition. One of the most confident grounds on which an endeavour had been made to mark a distinction between rheumatism and rheumatoid arthritis was the absence from the latter condition of cardiac disease. Endocarditis, they all recognised, was in the great majority of instances an evidence of rheumatism, but it was an expression of rheumatism which was specially prone to manifest itself in childhood and early adult life. It was by no means a common expression of rheumatism in middle life, but the majority of patients with chronic rheumatoid arthritis were those who were approaching or had reached middle age. Therefore it by no means followed that the absence of cardiac complications from the great majority of cases of rheumatoid arthritis proved that it was a condition quite distinct from rheumatism. Moreover, Charcot had stated that cardiac complications and valvular disease occurred fairly frequently in cases of rheumatoid arthritis. Trousseau had noted the occurrence in "nodular rheumatism," as he termed it, of lesions in the pericardium. For his own part, Dr. Hawthorne had been able to satisfy himself of the evolution of valvular disease during the study of an individual case of rheumatoid arthritis. Quite recently

they were taught that subcutaneous nodules were pathognomonic of rheumatism. Later experience had shown that similar nodules undoubtedly emerged during the progress of a certain number of cases of rheumatoid arthritis. In most instances the nodules of rheumatoid arthritis were larger and more persistent than the typical rheumatic nodule of the child and young adult, but considering the extremely chronic character of the majority of cases of rheumatoid arthritis it was not surprising that nodules when they occurred assumed a more persistent character than the subcutaneous nodules in the comparatively fleeting attacks of rheumatism which came on in childhood and early adult life. It seemed to him that it was a very suggestive fact that they observed nodules in rheumatoid arthritis essentially similar to those which were claimed as distinctive of rheumatism. He did not, however, wish to press the point too far because it had been shown that similar nodules also appeared in gout and in various other conditions. Still, he put it to them as a subject which was worthy of careful consideration. In regard to the development of muscular atrophies in chronic rheumatoid arthritis it seemed at first sight to savour of strong presumptive proof of the accuracy of the teaching that the phenomena of rheumatoid arthritis depended upon changes in the central nervous system. It was recognised that changes in the central nervous system and diseases of the spinal cord might produce muscular atrophies and it was known also that certain lesions in the cord were competent to produce severe articular disturbances, hence it was not unnatural to argue from the development of muscular atrophy that all the phenomena of the disease depended upon trophic nervous change. It had, however, been taught by Sir James Paget many years ago, and his teaching had not been seriously disputed, that any joint lesion might be followed by atrophy affecting the muscles which acted upon that joint. The joint lesion might be very slight, but the atrophy which followed might be very considerable. The atrophy was certainly not due to disease, for it was too rapid to be thus account for, and, further, it selected certain groups of muscles and neglected others, so that there was no issue upon the question of disease. The suggestion was that the joint lesion through the afferent nerves led to trophic disturbances in the spinal centres and the disturbances so produced were prejudicial to the nutrition of the muscle. No one was prepared to argue that in a case of a sprain the whole phenomena, including atrophy, depended upon trophic nervous disturbances, and it therefore followed that muscular atrophy in cases of chronic rheumatoid arthritis was no proof at all that the regular changes of marked rheumatoid arthritis depended upon central changes in the spinal cord. He was loth to commit himself to the definite opinion that chronic rheumatoid arthritis was due to changes in the trophic nervous apparatus, but he was not prepared to go so far as to say that he held very strongly that rheumatoid arthritis was certainly rheumatism. He did not think the charge of halting between two opinions was a serious one, for, although the cross-bench type of man was not popular amongst politicians, it could hardly be urged as a reproach in medical circles where so little was known and so much was vague and uncertain.

The meeting then adjourned to Tuesday, March 19th.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

Notification of Tuberculosis.—Meat-supply.

A MEETING of this section was held on Feb. 15th, Sir C. A. CAMERON, the President, being in the chair.

The PRESIDENT read a paper on the Compulsory Notification of Tuberculosis in which he said that the contagious nature of tuberculosis of the lungs was now universally admitted. In December, 1900, the Public Health Committee recommended the Corporation of Dublin to add tuberculosis of the lungs to the schedule of notifiable diseases. After a debate the further consideration of the proposal was adjourned for six months in order that more information on the subject should be obtained by the Public Health Committee and submitted to the corporation. The Local Government Board for England had received from several authorities applications for permission to make tuberculosis compulsorily notifiable but the Board had not given the required sanction. It was unlikely that the Irish Local Government Board would have acted differently had the Dublin Corporation adopted the report of the Public Health Committee recommending compulsory notification. Voluntary notification of tuberculosis existed in several English towns and payment was made for the notifications. There was no available fund in Dublin, or probably in any other Irish town, for such a purpose. Many English and Scotch towns had funds which enabled payment to be made for voluntary notification, whilst the Dublin Sanitary Authority could only pay for compulsory notifications. It was with this inability in view that the Public Health Committee recommended compulsory notification as the only kind that could be paid for. As to the desirability of making phthisis notifiable opinion seemed to be divided. It had lately been made compulsorily notifiable by the Norwegian Legislature. In some of the United States it was notifiable; for example, in Michigan and New York. The principal objection to notification was the difficulty in determining the proper time to notify. He thought that cases should not be notified unless the physical signs of phthisis were unmistakeably present or unless the bacilli of tubercle had been detected.

Dr. HENRY O'NEILL of Belfast read a paper entitled "Our Meat-supply and How it may be Improved." Meat inspection in Belfast was conducted under the control of the Market Committee of the county borough by the inspector of meat and provisions. The staff consisted of one superintendent of the public abattoir and three practical meat inspectors. After inspection the meat was stamped, and the public were recommended when purchasing meat from a butcher to see that it was marked with the stamp. Belfast was probably the first city in the United Kingdom to adopt a scientific method of meat inspection. It was well known that large quantities of diseased meat were sold for human food. Much diseased meat was taken to manufactories where various kinds of minced meats were made, such as German sausages, pork or meat pies, brawn and other delicacies, highly seasoned to cover any imperfections in quality. Dr. O'Neill then enumerated several of the diseases of domestic animals which made their flesh unfit for food, and he described some of the frauds practised by butchers, such as the dressing of carcasses to represent the flesh of totally different animals. At Leadenhall Market a hamper was found containing unborn lambs, dressed like Ostend rabbits. A retriever dog was killed and dressed as lamb; the owner was convicted and got three months' imprisonment. At the Central Meat Market, London, parts of a donkey were dressed and exposed for sale as deer. In Paris all meat was inspected, whether killed at home or foreign, and when the meat was found to be sound it was stamped with a stamp bearing the signature "P.P.," which meant Prefecture of Police. In Berlin all cattle to be offered for sale in the city had to be brought to the public abattoir, and the slaughtering of cattle anywhere else within the municipal boundary was absolutely forbidden. No butcher in Berlin might offer meat for human food which did not bear the official stamp of the inspecting department of the central market.

SECTION OF PATHOLOGY.

Stenosis of the Cardiac Orifices.

A meeting of this section was held on Feb. 22nd, Dr. A. C. O'SULLIVAN, the President, being in the chair.

Sir GEORGE DUFFEY exhibited a remarkable specimen of Stenosis of the Tricuspid, Mitral, and Aortic Orifices obtained from a man of fine physique, aged 33 years. As a boy he was in the Royal Hibernian Military School and from the records of that institution, furnished by the medical attendant, Lieutenant-Colonel Whittaker, A.M.S. (retired), there was evidence of his having had acute rheumatism, followed by valvular disease of the heart, before he was 13 years of age. He was under treatment at the Royal City of Dublin Hospital on different occasions during the last two years for heart disease, the most prominent symptom being ascites, for which he was repeatedly tapped, altogether 40 times. In the intervals between the tappings he was able to follow his occupation as a porter in a wine store. He drank heavily. On Jan. 8th, 1901, he was admitted to hospital suffering from extreme dyspnœa, cough, ascites, and œdema of the legs. He was much cyanosed. The pulse was feeble, irregular, and intermittent. The heart was

enlarged; its impulse was diffused and weak. He died on Feb. 4th. At the necropsy the heart was found to be greatly enlarged; it was somewhat square in shape and weighed 25 ounces. The pericardium was thickened and universally and closely adherent. The girth of the heart was 14½ inches and from the commencement of the aorta to the apex it measured eight inches. The right auricle was dilated. Its cavity measured four inches vertically by three and a half inches transversely and its walls were hypertrophied. The tricuspid orifice was extremely contracted. It admitted the middle finger only. The valves were thickened and fused together by their free margins in the form of a funnel which projected into the ventricle. The opening of the funnel was oval-shaped, measuring three-quarters by five-sixteenths of an inch. The right curtain of the valve was adherent to the septum. The walls of the right ventricle were hypertrophied and the endocardium over some of the columnæ carneæ especially was thickened. The pulmonary artery and valves were normal. The walls of the left ventricle were much hypertrophied, being eleven-sixteenths of an inch in thickness. The mitral valves were thickened, atheromatous, and contracted, forming a slit-like opening, smaller than the stenosed tricuspid and admitting the tip of the index finger only. The aortic valves were competent, but much thickened and calcified, and the orifice was so much contracted that it only admitted a No. 10 catheter. The left auricle was dilated; its lining membrane was thickened and atheromatous. The arch of the aorta was atheromatous. The liver and spleen were both enlarged and hard, and the capsule of each was thickened and adherent. Their weights were 3 lb. 8 oz. and nine ounces respectively. The pancreas was hypertrophied and hard. Both kidneys weighed together eight ounces and were congested.

CAMBRIDGE MEDICAL SOCIETY.—A meeting of this society was held on March 1st.—Dr. J. S. Hinnell showed a specimen of Sarcoma of the Choroid. The patient was a man, 53 years old, who, in September, 1898, complained of failing vision, specially towards his right side. The left eye was normal except for a little hypertropia. In the right eye vision was = $\frac{4}{60}$ and less than J.20. To external examination the eye showed nothing abnormal, but the ophthalmoscope revealed a considerable detachment of the retina inwards and upwards, with a sharp firmly defined edge crossing the circular red reflex from above downwards and inwards. The detachment was very dark, did not move with the movements of the globe, and showed no folds. On closer examination there were seen on the summit of the detachment some dark hæmorrhages and irregular whitish patches. The detachment shelved off from its summit gradually in the downward, inward, and upward directions, but towards the temporal side it was precipitous, with a firm dark edge, which overhung its base on that side and just hid the optic disc. There were two small retinal hæmorrhages. The detachment was from four to five millimetres deep. The eye was excised and sent to Mr. C. D. Marshall, the curator of the Moorfields Museum, who reported that it contained a sarcoma of the choroid and that the optic nerve was apparently not involved. The interesting features of the case seemed to be that in spite of the absence of such signs of intra-ocular growth as increased tension or enlarged episcleral vessels, yet the character of the detachment was so unusual as to create suspicion at once. For there were no whitish or grey reflex, no folds of the retina, and no flapping of the detachment; above all, the causes of an innocent detachment were absent, there were no myopia, no cyclitis, no hyalitis, no choroiditis, and no history of injury. The patient was last seen in April, 1899, when he seemed to be quite well.—Dr. Hinnell also showed a boy, eight years old, having a Foreign Body on the Iris. In May, 1897, he was struck in the left eye apparently with a stone. Seven days after the accident the left eye was nearly quiet, but flushed on exposure to bright light. The cornea was clear except for a minute opacity close to its centre. The aqueous was clear and the anterior chamber was normal. The iris acted well to light, there were no synechia and no iritis. On the pupillary edge of the iris was a minute foreign body not larger than a small pin's head and not unlike a piece of stone. The lens and the vitreous were clear. The minute foreign body had obviously pierced the cornea and become imbedded in the iris. The case was watched and in a few days the eye was quite quiet and apparently none the worse for the accident. There had been no attacks of inflammation nor any trouble with the eye since. Vision had not been affected. The foreign body was in the same place now (February, 1901) and the scar in the cornea could still be seen by careful examination.—Dr. Griffith exhibited (1) a specimen of Proliferating Papilloma involving both Ovaries which he had successfully removed from a young woman; (2) a boy, 11 years of age, from whom the Astragalus was Removed for Severe Talipes Equino-varus of the Left Foot; and (3) a woman who 18 months previously had the Left Breast and Axillary Glands Removed for Carcinoma and who two and a half weeks ago had a secondary growth, together with the breast, removed from the right side, but there had been no recurrence on the left side.—Dr. Boxall read a paper on the Dangers of Incomplete Abortion, in which he related a series of 18 cases seen mainly in consultation; in all of them abortion or miscarriage had taken place, but the uterus had been incompletely evacuated. One of these cases proved fatal from acute septicæmia, all the others recovered. He recommended that in such cases the uterus should be thoroughly emptied. Incomplete removal of the uterine contents was dangerous and futile, and operative interference was, in his opinion, likely to result in more harm than good unless the retained products were completely removed. For this reason curetting was often necessary. Douching the uterus with a strongly antiseptic solution was also frequently called for. But both measures required care in use—curetting that the uterine wall itself be not damaged, and the douching to prevent injurious absorption of the poisonous antiseptic used in the solution. After douching freely with a strong antiseptic solution—such, for instance, as 1 in 2000 sublimate—he was in the habit of adding water sterilised by boiling to the douche before the douche-apparatus was completely emptied, so that at last little more than sterilised water passed into the uterus and any excess of antiseptic was washed away. He had never found a blunt curette of the smallest use in cases where with the finger it was impossible to bring away the retained and adherent products. He thought it advantageous to use a fair-sized stirrup-shaped curette in preference to a mere bow, as at each scraping it denuded a larger surface and shortened the operation considerably when an extensive curetting was requisite. Hæmorrhage of a serious extent rarely occurred in the course of the operation, and all bleeding was as a rule controlled immediately by using the douche at 115° F. As a rule he made no direct chemical application to the denuded surface, regarding it as unnecessary when the douching had been efficiently performed, nor did he pack the uterus when decomposition had occurred, thinking it better in such cases to maintain free drainage through the cervix.

LIVERPOOL MEDICAL INSTITUTION.—The eleventh ordinary meeting of the session was held on Feb. 28th, Mr. Edgar A. Browne, the President, being in the chair.—Mr. Richard Williams reported two cases of the Removal of a Piece of Steel from the Vitreous by Means of Haab's Magnet. In the first case the metal had been in the eye for over four months. Cataract had been produced, but apparently the eye was otherwise sound. In the second case the foreign body had remained in the eye for over seven months and the eye had lost its vision from the first. A small incision was made in the cornea and when the magnet was applied the piece of steel shot out with great force and adhered to the point of the magnet.—Mr. Charles Shears was impressed with the value of Haab's magnet and considered that many eyes would be saved by its use. He referred to a case, however, in which the magnet had failed. The injury was a fortnight old, the cornea, the iris, and the lens were wounded and severe inflammatory reaction had occurred. The x rays demonstrated the presence of a piece of metal about the centre of the eyeball and Haab's magnet, which was used on three occasions, failed. Later the eyeball, being inflamed and softening, was removed. On opening the globe a small piece of steel was found firmly embedded in the abscess cavity between the back of the iris and the lens. Possibly the severe inflammatory reaction and inclosure of the foreign body which closely followed the injury was the reason why the magnet failed to draw the steel forwards.—Dr. W. Blair Bell related the case of a man, aged 65 years, who had used a Twig from an Elm Tree as a Bougie, a piece of which, two and a half inches long and as thick as a No. 12

catheter, had broken off in the bladder and was removed a week later by suprapubic cystotomy, the patient making a rapid recovery.—Dr. Blair Bell also related a case of Acute Primary Miliary Tuberculous Peritonitis in which a perfect recovery was made after laparotomy. He had performed the operation nearly a year ago. He advocated laparotomy in all such cases because (1) this was the only safe and effectual way of evacuating encysted fluid; (2) it produced the vasomotor shock (? dilatation) which he thought was responsible for the cure; (3) the condition of the Fallopian tubes could be investigated in women; (4) all adhesions could be broken down; and (5) the mortality after laparotomy was less than that after medical treatment.—Dr. T. R. Glynn referred to a case of tuberculous peritonitis with effusion where recovery followed the spontaneous discharge of the ascitic fluid through ulceration in the neighbourhood of the umbilicus. He had also seen cases of recovery in the same condition after paracentesis. While his experience led him to recognise the value of laparotomy in tuberculous peritonitis he thought that in the cases complicated with effusion tapping and evacuation of ascitic fluid might be resorted to with advantage before the graver operation.—Dr. W. Alexander remarked that many of these cases were not strictly tuberculous, no tubercle bacilli being found; it was surprising how easily such cases were often cured by draining and yet how difficult it was to treat cutaneous tubercle even by most heroic measures.—Mr. W. Thelwall Thomas mentioned a case of tuberculous peritonitis operated upon seven years ago, the boy now being in perfect health. He had removed a portion of the thickened peritoneum for microscopical purposes and sections exhibited miliary tubercle. He urged the importance of thus verifying the diagnosis and not trusting to naked-eye pathology.—Dr. T. B. Grimsdale remarked upon the apparently acute onset of tuberculous peritonitis. It was certain that tubercle could be present in the peritoneum without causing symptoms. The disease remained "latent" until some cause lighted it up and produced what appeared to be an acute onset. He thought that the removal of the fluid had a great effect in curing the disease and related a case in support of this view.—Dr. C. J. Macalister considered that statistics were required showing the results of surgical treatment of tuberculous peritonitis, both favourable and unfavourable; in his experience the prognosis was not bad in a number of cases treated by medical means. He cited the case of a child who had wasted greatly but had ultimately recovered on being sent to the country. He considered discrimination necessary in the selection of cases for operation; those cases in which large tuberculous masses were present were unfavourable for surgical treatment. —Dr. H. Briggs, Dr. E. T. Davies, Mr. G. A. Hawkins-Ambler, and Mr. Rushton Parker discussed the case and Dr. Bell replied.—Dr. Arthur Evans read a very interesting paper entitled, "With the Imperial Yeomanry Field Hospital in South Africa." The particular hospital was that associated with the name of the Countess Howe. Dr. Evans illustrated his paper by means of lantern slides from photographs taken during the various marches of the hospital which had done excellent work, had never been more than two weeks in any one place, and starting from Cape Town had gone through Bloemfontein to Pretoria, which place they had gone from and re-entered five times, after seeing service in various districts. Dr. Evans remarked upon 100 cases of gunshot wounds treated in the field.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on March 6th, Dr. W. Milligan, Vice-President, being in the chair.—Dr. J. Howson Ray showed a case of Pyonephrosis treated by Drainage and Abdominal Nephrectomy. The patient, a man, aged 24 years, received an injury to the right loin in February, 1900, having previously enjoyed good health. Four months later he noticed a swelling in the right loin and was admitted to hospital under the care of Dr. Dixon Mann. The swelling subsided with rest in bed and he left the hospital in three weeks' time. A fortnight later he was readmitted with a return of the swelling and this soon filled up the right loin, the hypogastrium, and the left iliac fossa. On August 15th Dr. Ray operated through the right linea semilunaris, excluded the peritoneal cavity, and on incising the kidney drew off 161 ounces of pus and water The left kidney was apparently normal. On Nov. 29th Dr. Ray enucleated the kidney through the right semilunar line without opening the peritoneal cavity. The ureter was found to be kinked about its junction with the renal pelvis. The patient made a good recovery, the left kidney acting well. The excised right kidney was shown and proved to be a case of traumatic hydronephrosis with secondary infection.—Dr. Dixon Mann also made some remarks upon the case.—Dr. F. J H. Coutts (for Professor S. Delépine) demonstrated the Widal Reaction for the Diagnosis of Typhoid Fever.—Dr. R. W. Marsden opened a discussion on the Diagnosis and Treatment of Typhoid Fever. He considered that a definite conclusion could be arrived at either from the history and clinical manifestations of the attack or from the use of specific tests. Separation of the bacilli from the stools, &c., being impracticable and tapping of the spleen unjustifiable reliance must be placed on the Widal reaction. The difficulties in connexion with the serum test were next dealt with. Dr. Marsden then mentioned the diagnosis of cases in which indefiniteness of the symptoms or their special localisation caused the difficulty and in both of these the greatest value was attached to the Widal reaction or in some of the latter group to the necessity of a bacteriological examination. Proceeding next to the treatment of typhoid fever the discussion was limited to (1) diet; (2) hydrotherapy; and (3) surgical interference. Dr. Marsden favoured the earlier administration of solid food in certain cases and on a definite plan, whilst whenever possible he laid great stress on the importance of a regular system of tepid baths from 75° to 85°F. The necessity for more accurate and earlier diagnosis of the various abdominal complications was then insisted on in order to allow of an operation being attempted with greater chance of success, since if so-called pathognomonic signs of peritonitis, &c., were waited for the time for intervention would often have gone by.—The following members took part in the discussion: Professor Delépine, Dr. J. Dreschfeld, Dr. Dixon Mann, Dr. J. Niven, Dr. E. S. Reynolds, Dr. Coutts, Dr. Moore, and Dr. McDougall.—Professor Delépine drew attention to the Dangers Attending the Use of Methods of Higher Dilution in performing the Serum Reaction which allowed the action of gravity to take part in the process. Professor Delépine among other remarks stated that the value of Widal's test should be estimated by comparing the results obtained between the seventh and fourteenth day of the fever by the test and by ordinary clinical methods respectively, the criterion being the subsequent course or termination of the cases. He had found that under those conditions the test had given reliable information in from 97 to 98 per cent. of the cases, and in some series in 99 per cent. Some suggestions as to the best method to be used had been made by Dr. Marsden who unfortunately had not based his remarks on his own personal experience. Over 6000 cases had been tested in Professor Delépine's laboratory since July, 1896, the method adopted by him having been adhered to from the first. He had found on the basis of numerous comparative experiments that if care was taken to prevent the bacilli running together as easily as they did in tubes, pipettes, or hanging drops (*Medical Chronicle*, March, 1897), it was simpler to use a uniform dilution of 1 in 10, and to estimate the degree of the reaction by its rapidity and completeness than to have recourse to dilution, which did not increase the accuracy of the reaction. With regard to the absence of reaction in a few typical cases of typhoid fever Professor Delépine had on previous occasions shown that this was observed chiefly in cases of typhæmia where the invasion of the blood by typhoid bacilli indicated an absence of reaction on the part of the tissues. In such cases the examination of the blood for bacilli could be resorted to with advantage.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 28th, Dr. E. Wearne Clarke, the President, being in the chair.—Dr. W. S. Porter showed a case of Diffuse Scleroderma. The patient was a woman, aged 39 years. There was a history of enlargement of the thyroid when she was about 18 years of age; also a history of head injury and unconsciousness lasting several hours at the age of 24 years and of liability to headaches ever since. She had been married for 14 years and had had nine miscarriages, all under three months, and one child subsequently which had lived. The scleroderma came on quite suddenly six months ago with a nervous attack in which the patient had twitching and was unconscious for three hours. The following day both the hands and the forearms and the right leg were considerably swollen and the swelling of the upper extremities had persisted ever since. A second seizure, similar in character,

but shorter in duration, occurred three months ago. Since then she had lost nearly two stones in weight and had become progressively weaker. When admitted into the Sheffield Royal Infirmary a fortnight before the hands and forearms were typically hard, pale, and waxy-looking and glossy, and hardly any movement was possible in the joints of the wrists and fingers, the hands being claw-like from the flexion of the first phalangeal joints. There were also large areas of leathery skin over the front of the thorax and abdomen, neck, and cheeks and in the lower extremities. The mouth was then drawn and widened to some extent by rigidity, altering the facial expression, and there was some difficulty in protruding the tongue and in the movements of mastication. The forehead and eyelids were fairly mobile. There appeared to be almost complete atrophy of the thyroid. The patient was bright and intelligent and there was no slowness of speech or mental defect. There was no acute pain but chiefly inconvenience from her hide-bound condition and a feeling of exhaustion. The temperature was normal, the pulse was rather quickened, and the heart, the lungs, the kidneys, and the alimentary tract were apparently normal. She had been treated for a fortnight by rest in bed and general friction with oil and warm bathing. Internally only thyroid extract had been given. There had been a very marked improvement generally and locally, and the skin, which had been quite dry for some days after admission, had begun to act with considerable relief to the patient. —Dr. S. White showed a case of "Scissors Legs."—Mr. R. Favell related a case of Cæsarean Section performed for obstruction of labour by a dermoid ovarian tumour. The patient was a primipara, aged 30 years. She had been in labour some hours when the medical man in attendance found a swelling below the presenting part. This he endeavoured to push up out of the pelvis but without success. Mr. Favell saw the patient about six hours after the onset of regular pains the os was then fully dilated; and a semi-solid, doughy tumour was felt in the back of the pelvis below the presenting part. A dermoid tumour of the ovary was diagnosed. The distance between the under surface of the pubes and the tumour was one and a half inches; the child was presenting by the breech. Cæsarean section was performed. After extraction of the child and placenta the tumour was brought out of the pelvis and removed. It was a dermoid cyst containing balls of hair, bones, and sebaceous matter. The uterine wall was sutured in the usual manner. There was very little bleeding. The patient made a good recovery.—Mr. R. J. Pye-Smith showed: 1. A girl, aged 10 years, the subject of Congenital Bilateral Displacement of the Hips. There was but little deformity and the movements of the limbs were almost perfect. A confirmatory skiagraph of the case was also shown. 2. A girl, aged five years, with Congenital Displacement of the Left Hip. A considerable limp was present but the movements of the limb were nearly perfect.—Dr. Porter read a paper on the Certification of the Insane, dwelling principally on the difficulty in dealing with certain forms of incipient insanity, cases of concealed insanity, and alcoholics, in conformity with the requirements of the ordinary lunacy certificate, and suggesting some modifications to meet special cases. He illustrated some of his points by reference to cases which had come under his own observation.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on March 15th at the Belgrave Hospital for Children, Dr. Edmund Cautley being in the chair.—Dr. George Carpenter showed two sisters with many curious Deformities of the Skull, Face, Fingers, &c. There were also developmental heart lesions and ruptures in the abdominal wall. There was no history of maternal impressions.—Mr. Sydney Stephenson pointed out that the eyes were displaced by some developmental fault in the position of the roof of the orbits and that the left cornea of the elder child was imperfectly differentiated from the sclerotic.—Dr. Sutherland and Mr. Clement Lucas also made some remarks.—Dr. William Ewart showed an infant, aged seven months, suffering from Asthma. During the paroxysms all the symptoms of true asthma were present, while during the interval the child was quite comfortable. Gastric disturbance and vomiting were dominant features of the case. Relief was obtained by regulation of the diet and the internal administration of apomorphine and iodide of potassium and hydrochloride of cocaine. Some benefit was also obtained from the application of expiratory pressure to the thorax.—The Chairman agreed that such cases were rare and were sometimes difficult to diagnose from capillary bronchitis.—Dr. Chapman, Dr. Chaffey, Mr. A. H. Tubby, and Dr. Sutherland also discussed the case.—Mr. F. Jaffrey showed, for Mr. T. Clinton Dent, a case of Sub-dural Abscess treated by operation. The patient, a lad, aged 12 years, made a rapid recovery.—Mr. Jaffrey also showed a Tumour occupying nearly the whole of the Sacrum and Coccyx in a girl, aged two years. It had been tapped twice and found to contain dark-coloured fluid not of cerebro-spinal origin.—Mr. Clement Lucas, who doubted whether the tumour had any connexion with the spinal cord and canal, said that the proper treatment would have been early excision.—Mr. Jaffrey, in reply, said he now agreed with Mr. Lucas's view.—Dr. Cautley showed a lad, aged about eight years, who developed left hemiplegia and athetosis after the occurrence of "fits." The probable explanation was a cortical hæmorrhage and thrombosis due to a fit with some persistent local irritation of the nature of sclerosis.—Dr. Cautley also showed two cases of Microcephaly in boys, aged respectively five and four years. Both patients had suffered from head-nodding associated with nystagmus in the elder. He was not prepared to recommend operation. —Dr. Leonard Guthrie, Dr. Turnbull, Dr. Sutherland, and others discussed the cases.—Dr. Henry Ashby (Manchester) read a paper on a case of Congenital Acute Nephritis. An infant was stated to have shown signs of dropsy on the second day after birth and to have vomited and passed but little urine. When examined at four weeks of age there was excessive œdema of the face, trunk, and limbs. The child died in uræmic convulsions. At the post-mortem examination the kidneys were found to be lobulated, and upon section they were pale, resembling the appearance of "the large white kidney." The heart was small and contracted, and the liver and lungs were gorged with dark blood. Microscopically the kidneys showed many greatly dilated convoluted and straight tubes; many blood casts and fibrinous casts were present; the epithelium for the most part was granular; and there were commencing peri-globular nephritis as well as interstitial changes between the tubules. There was no evidence of syphilis.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY. A meeting of this society was held at the dispensary on March 6th, Dr. C. H. Cattle, Vice-President, being in the chair.—Dr. Cattle read a paper on the Prognosis and Treatment of Epilepsy, with an account of a case complicated by mitral stenosis which had been under his observation for 18 years. The patient was a healthy girl till when about 20 years of age, during the mental strain of a competitive examination, she had her first definite attack of petit mal—short unexpected attacks of unconsciousness. The heart was carefully examined by Dr. Cattle and Dr. W. H. Ransom and was found to be normal. Three months' rest from her duties as head-mistress of a large school and dosing with bromides caused cessation of the fits for a time, but they returned on resumption of her duties. The first major attack occurred three years afterwards at night. One or two months would elapse between the attacks; then two or three would occur in rapid succession. Bromides were taken continuously and she continued her duties as head-mistress for nine years and then married, the attacks thereupon becoming more frequent. A year before this she was under treatment for excessive menstruation and an indistinct apical systolic murmur was noticed. Her anæmic condition then was thought to explain it, but in the course of two or three years its character altered to a loud presystolic rumble with palpable thrill and slapping second sound. The heart's apex was not displaced; the pulse was small and regular. The patient was very liable to bronchial attacks and occasional slight attacks of hæmoptysis. She had never had rheumatism in any form or any disease likely to cause endocarditis and Dr. Cattle could offer no suggestion as to the cause of the heart disease or trace its connexion with the epilepsy, but considered the prognosis very bad owing to the circulatory risks during an attack when respiration was for a short time suspended. As regards treatment Dr. Cattle thought success could only be hoped for when cases were treated at an early stage of the disease by drugs, mental rest, &c.—Mr. A. R. Anderson read notes of nine recent cases of Simple Fracture treated by wiring, five of the patella, two of the

olecranon, one of the tibia and fibula, and one of the femur. In four of the patellar cases the fracture was transverse, in one it was comminuted. In four the separation between the fragments varied from one and a half to two and a half inches, and in all these the lateral expansions of the capsule were badly torn. In the two olecranon cases the process was broken off at its base. No splints were employed in the after-treatment of these cases and passive movements were begun at about the end of 10 days, when the wounds had healed. They all recovered with perfect use of the joint. The fracture of the tibia was a long oblique one four and a half inches in length, and it was found impossible to keep the fragments in position by any means short of operation. The same difficulty existed in the case of fractured femur. The bone was broken rather above the middle of the shaft. At the time of operation an oblique fracture was found with the lower end of the upper fragment thrust through the quadriceps extensor, which effectually prevented reduction. Both these cases made good recoveries without noticeable deformity. In the femoral case there was an inch of shortening.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 15th, Dr. A. G. Barrs, Vice-President, being in the chair.—Mr. A L. Whitehead read a paper on the Treatment of Glaucoma by Excision of the Superior Cervical Ganglion of the Sympathetic. The paper will be published in THE LANCET shortly. —Dr. James Kerr (Bradford) said that the indications for the operation required defining; it was still purely experimental and probably might be useful in the rare cases of glaucoma which occurred in young adults and went on to blindness.—Mr. Moynihan, Mr. Lawford Knaggs, Dr. S. Long, Dr. J. E. Eddison, and Dr. Barrs also joined in the discussion.—Dr. J. Allan described a case of Tetanus treated by Antitoxin. The patient was an intemperate man, aged 54 years, who had sustained a compound fracture of the right thumb. At first he had no medical treatment. Twelve days later symptoms of tetanus began to develop and the disease was well marked when the antitoxin treatment was commenced on the nineteenth day after the injury. Antitoxin from the Jenner Institute was used and 180 cubic centimetres in all were administered during twelve days. There was marked relief after three days' treatment when 70 cubic centimetres had been given. Every night a draught of half a drachm of chloral hydrate was taken. The injured thumb recovered. The injections were given subcutaneously at various parts of the abdominal wall; no irritation or rash resulted; the case was one of moderate severity.—Dr. E. F. Trevelyan said that he had never seen any real benefit from the antitoxin treatment of tetanus, even including a case in which the antitoxin had been given by the intra-cerebral method.—Dr. A. Wear read a paper on Intra-uterine Fœtal Rigor Mortis. This condition, he said, was somewhat rare. Spiegelberg, in his recent work upon Obstetrics, said in his brief notes upon the condition: "This form of rigidity is undoubtedly extremely rare; indeed, so rare that Schwartz denies its occurrence." Batelsen and Scultze reported cases as early as 1856–57, and later on the continent others were recorded by Haake and Schroeder. Grigg, Boxall, Jones, and Davidson had since reported cases in England. Dr. Wear's patient, a big-boned woman, the mother of 10 children, was easily delivered of a stillborn child in a state of rigor mortis. The colour of the child was bluish and mottled; its limbs were rigid; its arms were semi-flexed at the elbows and the legs at the knees. The fœtus was well developed with no sign of maceration; the rigor mortis was so marked that it was impossible to bend or straighten the limbs. The labour was in this case, if anything, rather precipitate, but in a little woman with a small pelvic inlet the want of adaptation of the fœtus would greatly increase the dystocia. In the recorded cases forceps had generally been employed with success.—Mr. C. J. Wright discussed the paper.—Cases and specimens were shown by Mr. T. R. Jessop, Professor de Burgh Birch, Dr. E. W. Selby (Doncaster), Mr. W. H. Brown, Dr. T. Wardrop Griffith, Mr. E. Ward, Dr. A. L. Whitehead, Mr. P. J. Cammidge, Mr. Lawford Knaggs, Mr. H. Littlewood, Dr. Trevelyan, and Mr. Mayo Robson.

SOCIETY OF ANÆSTHETICS.—A meeting of this society was held on March 1st, Dr. J. F. W. Silk, the President, being in the chair.—Dr. R. J. Probyn-Williams, in conjunction with Mr. Harold Barnard and Dr. R. J. Howard, communicated a paper on a Modified Form of Dr. Schleich's Anæsthetic Mixture. The composition of the mixture employed was that recommended by Dr. Wertheim of Vienna—viz., chloroform one part, petroleum ether one part, and sulphuric ether two parts. It was pointed out that petroleum ether was now included in the appendix of the British Pharmacopœia, where it was stated to have a specific gravity of from 0·670 to 0·700, but that actually used in these observations had a specific gravity of only 0·643. Experiments were first made upon animals and some of the tracings thus obtained were thrown upon the screen. With petroleum ether alone it was very difficult to kill the animal (a cat). The blood-pressure fell slowly but steadily, the heart-beat became more rapid, and the heart-volume increased, owing probably to the rise in the venous pressure. These effects contrasted strongly with those produced when chloroform was inhaled. If the above-mentioned mixture was substituted for the petroleum ether there was hardly any fall in the blood-pressure noticed until the inhalation was pushed to the extreme. In practice a special form of Skinner's frame was used. 34 administrations had been undertaken varying in duration from five to 45 minutes. Induction was easy, free from struggling, and occupied on the average eight minutes. There were no excessive secretion of mucus or saliva and no signs of circulatory failure or cyanosis. The anæsthesia, though sufficient, was light and patients came round rapidly; relaxation was perfect. The pupils reacted as when A.C.E. was used; shallow breathing was not observed so long as the mixture was given sufficiently freely, there were no serious after-effects, and sickness was much the same as in chloroform.—Dr. Dudley Buxton said that he had tried one of Dr. Schleich's mixtures that was practically identical with that used by Dr. Probyn-Williams. On the whole his results were not very satisfactory, and although Dr. Probyn-Williams's paper encouraged one to try again he thought that many more cases would have to be recorded before a definite decision could be arrived at.—In reply to Mr. H. Hilliard, Dr. H. Low, Dr. G. Flux, and the President, Dr. Probyn-Williams said that the amount of the mixture used in each case had not been measured, but it must be given with a very free hand. It was not suited for the Junker's bottle.—Mr. Barnard said he thought that this was a very good example of the advantages of physiological experiments, the substance being tried upon animals before it was used on human beings; he had not specially determined the effects of change of posture.

WINDSOR AND DISTRICT MEDICAL SOCEITY.—A meeting of this society was held at the Guildhall, Windsor, on March 13th, Mr. W. B Holderness, the President, being in the chair.—Dr. R. Paramore showed (by permission of Dr. Norris) the Intestines from an Infant, aged seven months, who had suffered from intussusception. The patient had been treated successfully by hydrostatic pressure. The intussusception was seen to be completely reduced, but death had occurred 57 hours after the operation from ulceration of the cæcum.—Cases and specimens were also shown by Dr. A. G. Paterson, Dr. E. B. Hulbert, Mr. T. H. Scutt, and Dr. G. E. Hale.—Dr. H. D. Rolleston read a paper on the Uses and Abuses of Arsenic. Arsenic, he said, was a drug that often produced unexpectedly brilliant results—e.g., in preventing a tendency to catching cold and to the recurrence of labial herpes. For morning diarrhœa it often acted like a charm. Its uses as a digestive stimulant were referred to and its mode of action in pernicious anæmia and other blood diseases as well as in chorea was discussed. The question as to how chronic skin diseases were benefited by arsenic was raised. The mode of administration was next considered and stress was laid on the good results obtained by hypodermic use. The cacodylate of soda had at any rate in his experience been somewhat disappointing. In connexion with the effect of the drug on the skin, the production of keratosis, warts, and in long-standing cases, epithelioma was described. The irregularity with which peripheral neuritis developed was discussed and examples were given, a case of leukæmia being cited in which 105 grains of arseniate of soda were given hypodermically in 271 days without any neuritis following. The influence of other poisons, such as alcohol or those of disease, in accelerating the onset of neuritis was insisted on, and an example from Sir A. Cooper's lectures on arsenical paraplegia was quoted. Failure of the heart from the toxic effects of arsenic was also mentioned. In conclusion, remarks were made on the different action of the iodides and salicylates

on the one hand, which had been known to induce growths like sarcoma, and arsenic on the other hand, which, as already mentioned, in exceptional instances induced epithelioma.—The paper was discussed by Dr. F. Hawkins and Dr. Paterson.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—A meeting of this society was held on March 4th, Sir W. B. Dalby, the President, being in the chair.—Mr. Cheatle showed a patient upon whom he had performed the Complete Post-aural Operation. The whole antro-tympanic cavity had become lined by a dry glistening epithelium and he wished to ask how such an epithelial lining differed from the lining membrane of a cholesteatomatous cavity.—Dr. Urban Pritchard said that in the one case the epithelium was derived from skin and in the other from mucous membrane.—Dr. Dundas Grant urged the advisability of leaving the lining membrane of a cholesteatoma in certain cases.—Mr. C. A. Ballance said that in the ordinary form of cholesteatoma there was no lining membrane at all and that the appearance of a membrane was simply due to the flattening from pressure of the cells forming the cholesteatoma. He strongly deprecated leaving any portion of the cholesteatoma behind.—Mr. C. H. Fagge showed a patient with a Closed Meatus and with Facial Paralysis as the result of a Mauser bullet wound and asked whether the meatus should be opened up, considering that the middle-ear appeared to be intact.—Mr. Cheatle, Dr. Law, Dr. Milligan, and others discussed the case.—Dr. Dundas Grant showed some Teaching Diagrams for the Explanation of Weber's and Rinne's Tests.—Mr. R. Lake showed the following specimens: (1) Absence of Tendon of Tensor Tympani; (2) Pigmented Warty Growth from the Auricle of a Female, aged 50 years; and (3) Caries Necrotica of the Outer Antral Wall from a Child, aged four years.—Dr. StClair Thomson showed a Foreign Body which had remained innocuously in the Meatus for 26 years.—Dr. Macnaughton Jones referred to a case where a grain of shot had remained in the ear for 17 years.—Dr. Pritchard referred to a case where a cherry-stone had been in the ear for 50 years.—Dr. H. Jones read the notes of a case of Temporo-sphenoidal Abscess in which operation had been followed by recovery and showed a Specimen and Microscopical Sections from a child, aged two years, who died in convulsions 24 hours after the ordinary mastoid operation.—The cases were discussed by Mr. Cheatle, Mr. Lake, and Dr. Milligan.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on March 8th, Dr. Cresswell Baber, the President, being in the chair.—Sir Felix Semon showed a case of Malignant Disease of the Larynx treated by Thyrotomy and removal of the diseased area, shown seven months after the operation, occurring in a man, aged 47 years. The patient was in excellent health and there was no sign of any local recurrences.—Mr. Betham Robinson showed a specimen of Retention Cysts of the Lymphoid Follicles of the Vallecula. He also showed a case of Chronic Laryngitis, two cases of recent Perforations of the Septum Nasi, and a case of Tumour of the Base of the Tongue. In the last-named case the diagnosis lay between syphilis and sarcoma.—Dr. de Havilland Hall showed a man, aged 26 years, with the left vocal cord in the cadaveric position, paralysis of the parts supplied by the right seventh nerve, palsy of the right genio-hyo-glossus and of the left half of the palate. Dr. Hall thought that the symptoms were due to a disseminated polio-encephalitis.—Dr. L. H. Pegler showed a case of Exaggerated Deflection of the Septum Nasi and one of Advanced Malignant Disease of the Larynx.—Dr. Jobson Horne showed a case of Malignant Disease of the Tonsil with Glandular Enlargement.—Mr. F. Harvey showed a man in whom Total Extirpation of the Larynx had been performed for Epithelioma with a very favourable result.—Mr. H. Davis showed a man with most exaggerated Elongation of the Uvula and also some specimens of Post-nasal Adenoid Growths removed *en masse* with a curette.—Mr. P. R. W. de Santi brought forward a case of Sub-mucous Hæmorrhages in the Mouth.—Dr. Watson Williams showed a drawing of Congenital Fenestration of the Faucial Pillars.—Dr. Dundas Grant showed a case of Fixation of the Left Vocal Cord probably due to Ankylosis.—Mr. W. G. Spencer showed a boy with a Tumour of the Right Vocal Cord and a Swelling on the Right Leg. The latter was probably of syphilitic origin, but the opinion of the members was that the former was of a simple nature.—Dr. W. Permewan showed a case of Pharyngeal and Laryngeal Tumour for diagnosis, which was thought to be malignant.—Dr. F. W. Bennett also showed a Laryngeal case for diagnosis.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on March 13th, Dr. A. T. Wilkinson, the President, being in the chair.—Dr. W. Milligan showed a series of specimens illustrating some of the chief Intracranial Complications resulting from Suppurative Middle-Ear Disease and made some remarks as to the more usual routes by means of which disease spreads from the middle-ear to the brain.—Dr. Bannister and Mr. Southam showed a Papilloma of the Large Intestine which had produced symptoms of intussusception. The patient was a female, aged 77 years, who about once a month used to have a severe attack of diarrhœa. The growth was felt per rectum during one of these, and was pulled down by forceps, ligatured, and removed. It was attached to the margin of a considerable intussusception. Microscopically the tumour consisted of pure villous material. The patient had had a normal motion daily for the last 16 months.—Mr. Stanmore Bishop showed (1) a specimen of Ovarian Fibroma and (2) an Enlarged Gall-bladder the interior of which was entirely converted into a multilocular cystic tumour. There were no hydatids or gall-stones present.—Dr. Arthur Helme made some remarks on certain Degenerative Processes occurring in Uterine Myomata and showed specimens.—Dr. Powell White showed some sections of lung from two cases of Plague Pneumonia. The sections showed that the lesions were histologically identical with those of ordinary croupous pneumonia, the exudation consisting of fibrin, leucocytes, erythrocytes, and epithelial cells. The fibrous tissue of the lung and pleura was densely infiltrated with fibrin. The bacilli were found in the alveoli, in the subpleural lymphatics, and in the lymphatics accompanying the blood-vessels.

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this society was held in the University College, Dundee, on March 7th, Dr. A. J. Duncan being in the chair.—Dr. A. McGillivray showed eight ophthalmic cases, one of which was a case of Green Vision associated with a Subhyaloid Macular Hæmorrhage in a man, aged 29 years. The hæmorrhage came on seven weeks ago during straining at stool and was of the usual shape but only about twice the size of the optic disc. On the following day when looking out of the window and at a distance of nine feet from it he discerned on the window pane a circular disc three feet in diameter and of a brilliant green colour. The size of the disc varied as the distance from the window. The green colour remained for 21 days when it was replaced by a dark shimmering.—Dr. McGillivray also showed a case of Subhyaloid Macular Hæmorrhage similar in shape and position to the other but without any green vision.—Dr. W. E. Foggie showed, for Dr. G. Halley, a girl, aged 15 years, the left half of whose lower maxilla had been excised for recurrent Myeloid Sarcoma in November last. An interdental plate had been inserted 14 days after the operation and retained for six weeks. There was now no deformity and the patient was able to masticate fairly well with the right side.—Dr. Foggie also showed a case of Syringomyelia of the cervical region in which, together with a marked muscular wasting in the upper left arm, there were associated trophic changes in the left elbow-joint.—Professor J. A. C. Kynoch showed several specimens, including two Multilocular Ovarian Cysts.

BOURNEMOUTH MEDICAL SOCIETY.—An ordinary meeting of this society was held in the library of the society, Shaftesbury Hall Chambers, on March 13th, Dr. Arthur Ransome, the President, being in the chair. There were 27 members and three visitors present.—The minutes of the previous meeting were read and signed.—In reference to the communication as to the Congress on Tuberculosis to be held in London in July, 1901, the recommendation of the committee that the President be requested to represent the society as a delegate was adopted unanimously.—The President said that he intended being present at the Congress and would be pleased to represent the society.—A ballot was taken for the election of a candidate whose name appeared on the agenda and who was duly elected.—Dr. S. L. Clift showed a patient with Chronic Synovitis of the Left Knee with Effusion into the Joint.—Dr. W. Hooper Masters showed a patient, a man, aged about 50 years, with Torticollis.—Dr. C. D. Muspratt showed a patient with Ankylosis of both Wrist-joints and Right Hip-joint the

result of subacute rheumatism. After this patient had been examined the left arm was submitted to the Tallerman treatment of superheated dry air. During the time the arm was in the apparatus Mr. Tallerman, at the request of the President, made a statement as to the apparatus and the kind of cases which had been benefited by being submitted to superheated dry air.—Several members asked further particulars which Mr. Tallerman gave.—The President conveyed a vote of thanks to Mr. Tallerman.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The sixth meeting of the session was held in the Medical Library of University College on March 13th, Dr. D. S. Davies being in the chair.—Dr. J. Beddoe was elected an honorary member of the society.—Professor Michell Clarke showed the following specimens: (1) Tumour of the Right Optic Thalamus and Crus Cerebri; (2) Tumour of the Right Cerebral Hemisphere involving the Corpus Callosum; and (3) a large Intestine from a case of Dysentery.—Dr. J. L. Firth and Mr. C. A. Morton discussed the specimens.—Dr. T. Fisher showed a series of sketches and diagrams of Displaced Abdominal Organs.—Dr. J. Swain, Mr. Morton, Dr. Aust Lawrence, Professor Michell Clarke, and Mr. T. Carwardine spoke on the various conditions.—Mr. Morton read a paper on a case of Successful Operation for Diffuse Peritonitis from Perforation of the Appendix.—Dr. Swain, Dr. P. W. Williams, Mr. Paul Bush, Mr. F. Lace, Mr. Carwardine, Mr. W. H. Harsant, Professor Michell Clarke, and Dr. W. C. Swayne discussed the paper.—Dr. B. M. H. Rogers read notes on a case of Acute Pemphigus.—Dr. J. O. Symes and Dr. Fisher remarked on the case.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—The sixth meeting of the session of this society was held on March 11th, Dr. A. E. Maylard, Vice-President, being in the chair.—Dr. A. Maitland Ramsay showed a series of patients the subjects of Penetrating Wounds of the Eye, with Foreign Body in the Globe. The diagnosis of the condition had been helped by skiagraphy and in the treatment a modified magnet had been found of use.—Dr. W. L. Reid and Dr. A R. Ferguson exhibited a Papillomatous Cyst of the Ovary. The tumour had been removed by abdominal section and the patient had died the same evening from apoplexy.—Dr. G. H. Edington described a case of Epithelioma of the Mammæ of a Cat and showed macroscopical and microscopical specimens.—Dr. A. R. Ferguson showed microscopical sections of a Myxoma occurring in the Epidermis of the Finger after a punctured wound.—Dr. H. Rutherfurd showed a skiagram of a finger in which Dorsal Dislocation of the Middle Phalanx had occurred; the condition had been treated by the dorsal incision to divide the glenoid ligament.

PLAISTOW AND CANNING TOWN MEDICAL SOCIETY.—A meeting of this society was held on March 6th, Mr. H. A. Nelson being in the chair.—Dr. E. Hay showed two cases of Valvular Disease of the Heart in middle-aged men—one a case of greatly hypertrophied heart with a double aortic murmur; the other a case of both aortic and mitral incompetence with a greatly dilated heart. The cases were examined by those present and their conditions were discussed.—Dr. B. Dawson then gave an address of Dyspepsia and other Stomach Diseases. In the course of his address he stated that severe cases of neurasthenic dyspepsia were best treated by rest in bed. He pointed out the value of light solid food in some cases where "slops" were usually prescribed, and went on to describe the different clinical signs of dilated stomach, including the new method by the use of the x rays. He exhibited two patients with greatly dilated stomachs on whom he demonstrated the various signs described.—A discussion followed in which Mr. Nelson, Dr. J. Parker, Dr. J. Webster, and others took part.

ROYAL NATIONAL PENSION FUND FOR NURSES.—The annual meeting of this society was held last week at River Plate House, Finsbury-circus, E.C. Sir Henry Burdett, K.C.B., in moving the adoption of the report, said that it was with the deepest gratification that the council were able to announce that His Majesty King Edward VII. had graciously consented to remain patron of the fund and Her Majesty Queen Alexandra to remain the President. The total funds had increased during the year from £506,000 to £576,000. Mr. Eric Hambro, M.P., seconded the motion, which was carried.

Reviews and Notices of Books.

Essays on Consumption, together with some Clinical Observations and Remarks on Pneumonia. By J. EDWARD SQUIRE, M.D. Lond., D.P.H. Cantab., M.R.C.P. Lond., Physician to the North London Hospital for Consumption and Diseases of the Chest, and to the St. Marylebone General Dispensary. London: The Sanitary Publishing Company. 1900. Pp. 302. Price 10*s.* 6*d.*

THIS volume consists of reproductions of papers and articles which the author has at various times read before the medical societies or published in the medical journals. Dr. Squire has contributed freely to medical literature and some 25 articles appear in his book. The earliest dates back to 1889—"The Causation of Consumption"—a paper read before the Epidemiological Society, in which a full account is given of the various factors which tend to the production of pulmonary tuberculosis.

Chapter VIII. is an interesting one; it is headed "To what Extent can Legislation Assist in Diminishing the Prevalence of Consumption and other Tubercular Diseases?" The paper was read before the International Congress of Hygiene and Demography in 1891. Dr. Squire therein discusses various means which might be employed to combat the spread of tuberculosis. His remarks on "Notification" are a little difficult to follow. He says: "And yet there might be great advantage in requiring that a case of tuberculosis should, under certain conditions, be notified to the health officer." He does not define what he means by "certain conditions," but from his subsequent remarks we presume he would include amongst them the cases occurring in tenement houses, single-room dwellings, or common lodging-houses. He also points out with great frankness the difficulties which lie in the way of notification and which we have frequently dwelt upon. He is of opinion, however, "that the question of preventive legislation directed towards the diminution of tubercular disease is not one to be put aside because of its difficulties, though they are many and great." With most of his remarks we agree; to others, however, we must demur. General hygienic measures have done much to lessen the prevalence of tuberculosis, but to adopt some measures which have been proposed and which are beset with practically insuperable difficulties would inevitably end in failure.

As all the matter in this volume has been previously published we need not comment further; suffice it to say that there is the result of much valuable work scattered through the various chapters, the language employed makes them pleasant reading, and the latest phases of thought concerning "consumption" are here well reflected.

Sir William Broadbent contributes an "Introduction" to the collection of papers.

The Principles and Practice of Hydrotherapy: a Guide to the Application of Water in Disease. By SIMON BARUCH. M.D., Visiting Physician to the J. Hood Wright Memorial Hospital, &c. London: Baillière, Tindall, and Cox. 1900. Pp. 435, numerous Illustrations. Price 16*s.*

WE are informed in the preface that this book "is written by a general practitioner for the guidance of his colleagues." The experience is derived from a private hospital practice extending over a third of a century, and more recently from "special institution practice." We may congratulate the author on the advantage that he has taken of his opportunities for studying hydrotherapy, and he has done good work in publishing the conclusions at which he has arrived for the benefit of the medical profession in general. The work, however, is not a panegyric upon hydrotherapy, but a calm survey of the uses of water as a remedial agent precisely as medicinal remedies are discussed in the text-books on therapeutics.

The first part of the book deals with the physical properties of water and its mode of action in health. We do not remember to have seen such a complete and thorough discussion of the subject. Laboratory experiments are freely discussed and the author has made himself well acquainted with the literature of the subject and marshals his facts in an interesting and scientific manner.

In order properly to comprehend the action of water upon the surface of the body the anatomy, physiology, and functions of the skin must be understood, and Dr. Baruch therefore pays a due amount of attention to this subject, and the effects of hydriatic applications upon the distribution and composition of the blood are also fully considered. The author is of opinion from his clinical and experimental experiences that the changes produced by the thermic and mechanical stimulation arising from hydriatic procedures are very intense and far reaching; further, "that an enormous influence must be exercised by procedures which impress such changes upon the calibre of the vessels, the action of the heart, and the composition of the blood in health, and that its effect in disease must be equally pronounced."

The second part of the book is devoted to the practice of hydrotherapy. The various methods of applying water in disease are clearly and minutely described and illustrated, the *rationale* of each procedure is discussed, and its special therapeutic indications are outlined. The technical details having been thus fully considered the reader is introduced to the practical application of hydrotherapy in acute and chronic diseases.

We notice a marked absence of constant reference to the various spas and health resorts. This is commendable and tends to concentrate the reader's thoughts on the use of water as a remedial agent apart from the general effects of the *régime* of a recognised institution. The author maintains that a fallacious idea still prevails that cases of chronic disease must be sent away from home in order to obtain good results from hydrotherapy. He states that while it is true that the treatment in institutions offers the best prospect in chronic cases, the reason lies not so much in the facilities offered by them as in the experience and consequent skill acquired by physicians from the large *clientèle* of such establishments, and he believes that the requisite knowledge may be as readily acquired by the practitioner as is that of any other department of therapeutics. The question is a difficult one. No doubt Dr. Baruch is, generally speaking, correct, but the thoughts of the reader will at once advert to the so-called hydropathic establishments in this country which were, in the first instance, founded for the purpose of furthering the advantages of hydrotherapeutics, and although in a few this object is still upheld the majority have been turned into resorts for social gaiety, carried to an extent which by no means tends to the comfort and welfare of patients. Returning, however, to Dr. Baruch's book, we can speak in high terms of the manner in which his objects have been carried out, and the volume will serve as a good work of reference to students and practitioners of medicine on a subject but scantily dealt with in ordinary text-books.

A Text-book of Histology, including Microscopic Technic. By A. A. BÖHM, M.D., and M. VON DAVIDOFF, M.D., of the Anatomical Institute in Munich. Edited, with extensive additions to both text and illustrations, by G. CARL HUBER, M.D., Junior Professor of Anatomy and Director of the Histological Laboratory, University of Michigan. London and Philadelphia: W. B. Saunders and Co. 1900. Pp. 500. 351 Illustrations. Price 15*s.*

THIS volume, an authorised translation by Herbert H. Cushing, M.D., of the Jefferson Medical College, Philadelphia, contains substantially all the subject matter and illustrations of the second revised German edition of Böhm and Davidoff's well-known "Lehrbuch der Histologie des Menschen." Additions to the German text have been freely made, and more than 100 illustrations, the majority of which are original, have been introduced into the present work. These additions are to be found chiefly in the section which deals with the modes of termination of sensory and motor nerves. Here excellent descriptions and illustrations are given from the paper by Huber and Lydia de Witt, published in the *Journal of Comparative Neurology*.

We already possess an excellent translation of the "Lehrbuch der Histologie" of Stöhr, and the present work, though somewhat different in arrangement, essentially covers the same ground. The introduction to "Microscopic Technic" has wisely been condensed, so that only the simpler methods of fixing, hardening, and staining are described. The formula for Delafield's hæmatoxylin omits to give the necessary methyl alcohol, and Kultschitzky's hæmatoxylin, which is invaluable as a modification of the Weigert-Pal method, might well have been included among the logwood stains. The use of hæmatein in place of hæmatoxylin crystals, or the addition of various chemical agents which hasten the ripening of stains made with the latter, is now such a general practice that these details might have been supplied with advantage, and the use of carminic acid instead of carmine is useful for a much larger variety of stains than merely for Mayer's paracarmine, the single example which is given.

The use of compressed carbon dioxide, as recommended by Mixter, in place of the common ether-spray is of great service. The advantages of this are pointed out quite clearly, but the description which is furnished of the methods of preparing and soaking tissues for this apparatus are so meagre that we are satisfied no histologist would think of following the directions which are given. The various methods of impregnation with salts of gold, silver, or mercury might with advantage have been transferred to this introductory chapter instead of being distributed under the special technical methods which follow the sections descriptive of special organs or systems. The formulæ for the preparation of injection masses should have been accompanied by more explicit directions for performing artificial injections, and the method suggested, in which a syringe is used, is not often successful except in the hands of a skilled worker, and can never be regarded as more than a rough though rapid method which compares unfavourably with the perfect injections which can only be obtained by the use of an apparatus where a constant pressure of mercury, water, or air is employed. In order to obtain the best results in histological work it is also absolutely necessary in the case of the lower animals to inject the entire blood system with some fixing fluid, and we think that the importance of this procedure might have been pointed out, for although the majority of the illustrations are those of human histology some are necessarily made from preparations of the organs of the lower animals.

Both the text and illustrations of the book are, as a rule, excellent. Of the latter a considerable number have already found a place in many recent English text-books. The figures given of the minute structure of bone-marrow, germinal tubules, the spleen, hairs and hair follicles, and the mammary gland are obviously most accurate representations. The plate of a cell-ball from the glomus caroticum of man is so good that it is a matter for regret that there are no figures of such organs as the pituitary and pineal bodies. The section which deals with muscular tissue, though differing widely in its description from that adopted in most English works, treats the subject with great clearness, and attention is drawn to the histological appearances which indicate that the development of muscle fibres continues throughout the life of the individual. This tissue is to be

regarded as in a perpetual state of transition, the destruction and compensating reproduction of its elements going on hand in hand. The continuous loss of substance is replaced by new elements or myoblasts which are developed from free sarcoplasm which is characterised by rapid growth and increase in the number of its nuclei.

The description and illustration of the liver leave nothing to be desired. The figures of the bile capillaries displayed by the method introduced by Kopsch and the reticulum (Gitterfasern) of connective tissue between individual cells which Kupffer has demonstrated by a special gold-chloride method are exceedingly good and give a knowledge of the minute anatomy of the liver which is quite up to date.

The section which deals with the spinal cord and brain, together with the technique concerned in the demonstration of the histology of the central nervous system, is, in our opinion, not quite equal to the rest of the volume. Apart from the methods the whole subject occupies only about 14 pages, and of these three are occupied by full-page illustrations. In a text-book which is in many respects the best that has been written a somewhat fuller amount of information might have been given. The English student will in particular feel the want of figures of the various regions of the medulla, and if a good description of the variations in histological structure exhibited by various regions of the cerebral cortex and hippocampus had been supplied a real want would have been met, as this important information is omitted in most English text-books. In the technique Stroebe's beautiful aniline blue method and Kultschitzy's hæmatoxylin method might have been included as they are so good and trustworthy. Pal's method as given in the text is by no means the best of the various modifications of the one originally devised by Weigert. The omission of Marchi's method may possibly be defended on the ground that its use is purely pathological, but Marchi's fluid is employed in the methods of both normal and abnormal histology. It is undoubtedly difficult to include in one volume with descriptive histology an exact and detailed account of methods: these alone would require a volume. Historical accounts of such methods as Golgi's are out of place in a text-book of human histology. A few selected methods, the result of actual experience, are the ones required in a book of this kind. It is for the descriptive matter, and especially for the excellent illustrations, that the work will be useful, and as a thoroughly trustworthy and accurate account of human histology this text-book, which deservedly possesses a great popularity in Germany, may be warmly recommended to the attention of students in this country.

Transactions of the Ophthalmological Society of the United Kingdom. Vol. XX. Session 1899–1900. London: J. & A. Churchill. 1900. Pp. 338. Price 12*s.* 6*d.*, or subscription to the Society, which includes the volume, £1 1*s.* annually.

THIS volume opens with a short introductory address by Mr. G. Anderson Critchett, in which he reviews the methods that have been employed for the extraction of cataract during the last century and a half and dwells upon the improvements that have been made. The address is succeeded by the Bowman Lecture which was delivered on June 15th, 1900, by Mr. R. Marcus Gunn, who took for his subject "Visual Sensation." The effects of light on chlorophyll granules and on pigment cells were described, with the structure of the retinal elements as given by the most recent inquirers, and the general physiology of vision was discussed. The "Reports" follow Mr. Gunn's lecture; the subjects are arranged topographically, the diseases of the eyelids occupying the first place, then in succession come those of the conjunctiva, cornea, iris, retina, and choroid; intra-ocular tumours are next considered and finally the diseases of the orbit, congenital abnormalities, and injuries and operations.

It is impossible to notice the numerous individual cases that appear in this volume, many of which are of considerable value, but we briefly refer to one or two of them. Mr. W. T. Holmes Spicer describes a case of spring catarrh and gives illustrations of the appearances presented by sections of the mucous membrane of the conjunctiva under high powers of the microscope. The sections exhibit some thickening of the epithelium which in places dips into the substance of the tissue beneath in the form of finger-like projections which, when cut across, give the appearance of nests of cells. Mr. Arnold Lawson brought under the notice of the society a rare case which is here fully reported, of a cicatrix horn growing from the cornea. Mr. Treacher Collins suggested that the pathology of this condition was that there had been originally a perforating ulcer of the cornea leading to exposure and inflammation of the iris, which was followed by the formation of a mass of granulation tissue developing into a pseudo-cornea. This becoming prominent, dry, and scaly constituted the horn. Mr. John Griffith has an article on Iritis as a Sequel to Gonorrhœa. The intervals between the occurrence of the two diseases are very considerable—in one case 15, in another 12, years—and corroborative evidence seems to be required. Three cases of Ophthalmitis are recorded by Dr. Percy Flemming occurring in children with pseudo-glioma; one resulted in recovery and two proved fatal from meningitis. Dr. Flemming regards the meningitis and the ophthalmitis that proceeded concurrently in these cases as the result of a pyæmic or septicæmic condition. He thinks middle-ear suppuration to be a likely source of the pyæmic process in some cases and recommends that the ears should be examined in all cases of ophthalmitis and that both tympanic membranes should be punctured even if they appear to be healthy. Interesting accounts are given of various intra-ocular growths by Mr. Work Dodd, Mr. J. Herbert Fisher, and Dr. Charles R. Box. Various interesting cases of changes in the fundus oculi are recorded, especially a series reported by Dr. F. Menteath Ogilvie of concussion injuries of the eye, one of the characteristic features of which is a hole at the macula. Dr. Ogilvie has collected 15 of such cases. The holes in general have a very sharply-defined edge, though radiations may proceed from it. As a rule there is a well-marked central scotoma, but the intensity of this varies. The last article which we shall mention is one by Dr. Walter Edmunds on experimental exophthalmos and enophthalmos in which the effects of the ablation of the thyroid body are well given. The volume contains the accounts of many interesting cases and is enriched with 14 plates, many of which are coloured.

This volume of the Transactions contains an index of volumes XI.–XX. inclusive, which is very complete and will prove useful to all who have occasion to refer to the "Reports." A list of the additions to the library since November, 1900, also accompanies the volume.

L'Avortement. By Professor P. BROUARDEL. With 15 Figures in the Text. Paris: J. B. Baillière et Fils. 1901. 8vo, pp. viii.–376. Price 7 fr. 50 c.

THE occurrence of natural abortion is so frequent and the practice of procuring criminal abortion is spreading to such an extent at the present day that the whole question is one of great interest to those practising obstetric medicine both from the medical and the medico-legal point of view. The distinguished position and the great experience of the author of this work render it one of much value.

In a historical review Professor Brouardel shows that

amongst primitive peoples there existed the most complete indifference towards the preservation or destruction of the products of conception. Aristotle and Socrates both thought the production of abortion a perfectly justifiable measure, and Hippocrates was the first to state that he would neither countenance nor carry out such a procedure. That it was frequently practised in his day is shown by the long list which he gives of the complications that may ensue.

After considering the history of the subject, the author gives some very interesting facts as to the period of pregnancy at which abortion is most commonly procured. He also points out that at the present time there can be no doubt but that large numbers of so-called midwives in Paris practise as abortion-mongers. The number of such women is too large to allow of their making a livelihood by legitimate practice. In considering the etiology of natural abortion a great deal of information is given as to the action of various metallic and organic poisons upon the uterus. The various procedures that may be employed for the production of criminal abortion are described under the following heads. 1. The administration of abortifacient substances. 2. Various manipulations that may be carried out either upon the body, such as massage or forcible compression of the abdomen, or direct manipulations upon the vagina, the cervix, and the body of the uterus. The plants that are regarded as having a direct abortifacient effect upon the uterus are as follows: yew, savin, juniper, arbor vitæ, tansy, rue, and ergot. The question as to whether it is possible for a woman herself to introduce various substances directly into the uterus is answered in the affirmative. The immediate and remote effects of abortion are dealt with, including the possibility of sudden death and the occurrence of septic infection. The last two sections deal with some most important medico-legal questions—the examination of the patient, the examination of various substances expelled from the uterus, the performance of necropsies, and the recognition of the signs of recent abortion.

In the last section the author gives a number of examples of the kind of questions that the medical expert in such a case may be called upon to answer.

In an appendix the details of a number of important cases are cited, illustrating various points in such cases, and containing a number of very interesting medico-legal reports. The book is well worthy of its distinguished author and will be of assistance not only to medical jurists but also to anyone who may have to give evidence in one of these very serious and often very difficult cases.

Report on the Water-supply of the County of Essex. By JOHN C. THRESH, D.Sc. Lond., M.D. Vict., D.P.H. Camb., &c. Chelmsford: Meggy, Thompson, and Co. Pp. 180. Price 3*s.* 6*d.*; in cloth, 5*s.*

THIS little book gives an excellent description of the water-supply of Essex. It deals briefly with the geological formation of the county, with records of the average amount of rainfall, and gives many analyses of the water obtained from the subsoil and from deep wells. There are no less than 11 maps showing the river basins, the undulations of the chalk, and the distribution of the water mains in places which have a public supply. The most interesting map is one which gives the situation of the deep wells in the chalk and which marks the distribution of those which yield what Dr. Thresh calls "soda-water"—a beverage which must not be confounded with the aerated water popularly known by that name. The author disarms criticism by saying that the book was hurriedly prepared for the use of the Essex County Council, and he invites corrections and suggestions for alterations. In the compilation of such a report the author must necessarily depend to a very large extent on the information which is supplied to him, but in the case of a quotation it is always best that the passage should be distinctly marked in the usual manner. In Dr. Thresh's book this is not always done; for example, on p. 88 the reader is struck by a footnote referring to the text above to the effect that "These opinions are certainly curious and imply a very limited knowledge," &c. On looking back two pages it is evident that the author of the curious opinion is either an officer of the Local Government Board or Mr. Sasse, the borough surveyor of Chelmsford. For the casual reader a good index is desirable; for the busy man using a work for reference an index is almost indispensable. We hope to see one in the next edition of this book.

Dr. Thresh's report should be read by all county medical officers of health, and all County Councils in the country should try to obtain such a report in the case of the districts which they represent.

LIBRARY TABLE.

Medical and Surgical Nursing. Edited by H. J. O'BRIEN, M.D. New York and London: G. P. Putnam's Sons. 1900. Pp. 278. Price 6*s.*—This manual for nurses is the united work of several authors, mostly connected with the St. Joseph's Hospital Training School for Nurses, St. Paul, U.S.A. The contents consist of 15 chapters, of which the most important are those dealing with asepsis and antisepsis, general nursing, and cooking for the sick. The latter is, perhaps, the most valuable contribution of the series; it advocates precision and claims that cooking is an exact science and "cannot be done for the sick by guesswork without great risk." This plea for accuracy in the feeding of the sick is in marked contrast to a slovenly article on Infant and Child. In this latter chapter accuracy is sneered at, nurses are recommended to allow infants to consume as much food as they fancy, and the troubles of teething are regarded as myths. "They are due to improper methods of feeding," and such troubles would be many, we fancy, among infants brought up on the methods advocated. With the exception of three or four articles it is difficult to see what useful object the contents of this book can subserve in the training of nurses. Many better works on the same subject have been published both in England and in America; the price, too, is almost prohibitive for a nurse, and considering that the book is small and contains no illustrations it is altogether too expensive.

Transactions of the American Orthopædic Association. Vol. XIII. 1900. Philadelphia: published by the Association. Pp. 356.—This volume contains in all 36 papers, including the Presidential address delivered by Dr. H. M. Sherman of San Francisco. Dr. Sherman's address gives details of the results of an inquiry into how far orthopædic surgery is taught as a special subject in American medical schools. Out of 76 colleges only 38 mentioned the subject as being taught, while 60 "specialised" in gynæcology, 59 in pediatrics, and 58 in neurology. Of the various papers perhaps the most notable are those of Dr. A. M. Phelps upon the Treatment of Abscesses of the Joints with Glass Speculum, Drainage, and Pure Carbolic Acid, with a report of 70 cases. Dr. Phelps opens the abscess cavity, removes diseased tissue, and fills the cavity with pure carbolic acid which is allowed to remain for one minute. The acid is then washed away with alcohol which is in turn washed away with a 2 per cent. solution of carbolic acid. A large glass drainage-tube is then placed in the cavity, which tube is packed with gauze or some similar material. The tube is of as large a diameter as the cavity will take. Patients thus treated were discharged from hospital within three weeks from the date of the operation. Another interesting paper is that by Dr. R. W. Lovett of Boston upon the Mechanics of Lateral Curvature of the Spine. By means of using cadavers and living models flexion simultaneously forwards

and laterally was shown to be accompanied by rotation of the bodies of the vertebræ. In forward and lateral flexion the bodies of the vertebræ, both in the cadaver and the model, turned towards the convexity and the spines towards the concavity. In backward flexion with lateral flexion just the reverse occurred. The chief conclusion of the paper was, therefore, that to correct the torsion observed in scoliosis the spine should be extended and that side bendings should be taken from extended positions.

The Law of Joint-Stock Companies Acts, 1862–1900. By JAMES WALTER SMITH, LL D. London: Effingham Wilson. 1901. Pp. 212. Price 2*s.* net.—This volume, which is one of Mr. Wilson's legal handy books, gives a great deal of information in a comparatively small space about the law relating to joint-stock companies. Directions for forming a company are also given. A feature of the book is the index, which is very full.

La Surdi-Mutité: Étude Médical. Par ÉTIENNE SAINT-HILAIRE. (*Deaf-Mutism: A Medical Study.* By ÉTIENNE SAINT-HILAIRE.) Paris: Maloine. 1900. Pp. 354.—Dr. Saint-Hilaire has been in charge of the Seine Department Institute for Deaf Mutes since its foundation in the year 1893 and has made the very best use of the unequalled opportunity of studying this affliction which has been thus placed within his reach. The result is the work that he has now presented to the profession. Dr. Saint-Hilaire's is the first monograph on the subject in French and it is at the present time the most complete work on the subject extant, the recent works of Holger Mygind and Kerr Love as well as no fewer than 670 works and papers having been made use of in the compilation of the statistical and other portions of the book. The first chapter deals with Definition and Classification, and the second with the Distribution of deaf mutes, not alone in France, but also in the whole world, the distribution in France naturally being most minute. The third chapter, under the heading Pathogénie, deals first with Heredity, this being considered under the subdivisions of similar and dissimilar heredity. By similar is meant the transmission of the disorder from the parents, grandparents, or collateral branches, dissimilar being the existence of deaf-mutism in the progeny of the subjects of other nervous disorders, "La maladie nerveuse qui se transmet se transforme a dit Legrand du Saulle; c'est ainsi qu'on voit se succéder, dans les mêmes familles, la manie, &c." (p. 56). Upon the consideration of heredity follows the consideration of consanguinity, of causes of degeneration and of acquired deaf-mutism. The fourth chapter consists of a thorough description of the Pathology and Pathological Anatomy of Deaf-mutism; and the last three chapters deal with Symptomology, Diagnosis and Prognosis, and Prophylaxis and Treatment respectively. Dr. Saint-Hilaire has exercised the greatest care in the production of his book and it will amply repay perusal and will form a valuable addition to any medical library. In particular the chapter on Prognosis and Treatment will be of the greatest assistance to all who have to treat or to advise in the treatment of this most unfortunate class of humanity.

The Nursing Profession: How and Where to Train. By Sir HENRY BURDETT, K.C.B. London: The Scientific Press, Limited. 1901. Pp. 390. Price 2*s.* net.—This is the third year of publication of Sir Henry Burdett's useful book of information for nurses and would-be nurses. The introductory chapters contain an account of the general requirements of the schools and an excellent abstract of the laws which affect nurses in so far as their duties are concerned. The remainder of the book is taken up with details of hospitals and other training institutions, of establishments where nurses are employed but not trained, of Government and other appointments, together with a list of colonial, foreign, and American hospitals and nursing institutions. A list of provident funds, examining bodies, and associations for the benefit of nurses, is also given.

JOURNALS AND MAGAZINES.

THE *Medical Magazine* for March contains an article upon Duodenal Ulceration by Dr. H. W. Syers which sums up very well the difficulties of diagnosing the generally obscure cases of this affection. Dr. Syers points out that, as is well known, the class of patient usually the subject of duodenal ulceration is quite different from that of the anæmic woman in whom gastric ulcer most commonly occurs. Middle-aged men are the subjects of duodenal ulcer and commonly—a point which Dr. Syers does not mention—they are men who take alcohol too freely. Dr. Syers lays great stress upon melæna as the most important symptom. As regards the etiology of the affection we cannot entirely agree with Dr. Syers's opinion that this will be only thoroughly understood when the anatomical distribution of the small vessels in the intestinal mucous membrane has been worked out. There is more chemistry in the matter than this, we suspect. Dr. Syers believes that Cardinal Wolsey died from duodenal ulceration. Dr. R. Tanner Hewlett contributes a comprehensive paper on Mediterranean or Malta fever. He gives typical charts of the long undulating pyrexia and a photograph of cover-glass preparations of the micrococcus melitensis. The Prison Act of 1898 is discussed by Mr. A. G. Whiteway who raises the question of paying greater attention to the previous history and the present mental and physical conditions of culprits. Greater facilities should be given, he holds, for training medical men in the necessary work, and medical students should be instructed at prison infirmaries.

The *Practitioner* deals mainly this month with Malaria and those who have lately added to our knowledge of the disease. Just as more popular magazines are wont to heighten the interest of a forthcoming serial by giving beforehand incidents concerning the life and habits of its author, so the *Practitioner* preludes the articles on malaria with short biographical notices of some of the chief workers in this field. Then follow articles by Dr. Patrick Manson, Mr. D. C. Rees, Dr. Louis W. Sambon, Mr. E. E. Austen, and Dr. Tanner Hewlett. In "The Month" the editor comments on Mr. Burdett-Coutts's criticism of the Royal Commission on medical affairs in South Africa.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., M.D. Cantab., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. XXVI., Nos. 3 and 4. London: C. J. Clay and Sons. Feb. 28th, 1901. Pp. 165. Price 10*s.*—The articles contained in these numbers of the *Journal of Physiology* are: 1. The Movements and Innervation of the Small Intestine, by Mr. W. M. Bayliss and Dr. E. H. Starling. The authors in a previous paper had taken for the subject of their experiments the dog; in the present one their researches were made upon the rabbit and upon the cat. 11 woodcuts giving tracings accompany the text. 2. On the Effects of Venous Obstruction on the Secretion of Urine, by D. H. de Souza. This observer finds that either partial or complete obstruction of the renal vein always causes a diminution or cessation of the urinary secretion, and further that the flow of urine from the kidney is (other things being equal) directly proportional to the velocity of the blood-flow through the kidney. He does not consider that the function of the glomeruli has been quite satisfactorily determined. 3. On Metabolism in Forced Feeding, by Dr. W. Hale White and Dr. E. I. Spriggs, with three figures in the text. 4. On a Method of Estimating the Interference with the Hepatic Metabolism Produced by Drugs, by Dr. D. Noel White and Dr. J. Eason. 5. On the Origin from the Spinal Cord of the

Vaso-dilator Fibres of the Hind Limb and on the Nature of these Fibres, by Mr. W. M. Bayliss. The author shows that there are vaso-dilator fibres in the posterior roots of the fifth, sixth, and seventh lumbar, and in the first sacral, nerves. They pass directly into the lumbo-sacral nerves. Their trophic centres are in the ganglia of the posterior roots. There are 17 figures in the text. 6. An Attempt to Estimate Fatigue of the Cerebral Cortex when caused by Electrical Excitation, by Dr. A. G. Levy, with 10 figures in the text. The plan adopted in this research was to anæsthetise the animal, which was usually a cat, though occasionally a dog, and to stimulate the cortex with a current of electricity; the length of time during which the muscles affected by such stimulation continued to contract and the vigour of their contraction were then determined. 7. The Physiological Effects of extracts of Nervous Tissues, by Dr. W. D. Halliburton, with 21 figures in the text. The injection of brain and other nerve extracts produces a fall of blood-pressure in cats which the author attributes to the presence of cholin. 8. The Composition and Action of Orchitic Extracts, by Dr. Walter E. Dixon, with 25 figures in the text. These extracts lower the blood-pressure. 9. On the Action of Iodine and Iodides, chiefly with regard to the Muscles of the Frog, by Dr. Ralph Stockman and Dr. Francis J. Charteris. 10. On the Nature of the Sugar Present in Normal Blood, Urine, and Muscle, by Dr. F. W. Pavy and Mr. R. L. Siau. The part concludes with the Proceedings of the Physiological Society.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., M.D. Cantab., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Index to Volumes I. to XXV. inclusive. London: C. J. Clay and Sons. February, 1901. Pp. 192. Price 15*s*.—This is a much-needed and excellently executed volume. In looking up authorities and the labours of previous observers on any given subject nothing is more wearisome than to have to look through the indices of numerous volumes, especially when, as in the case of the *Journal of Physiology*, there is only a table of contents and a list of authors' names prefixed to each volume. The scheme here adopted is sufficiently comprehensive and no difficulty can arise if either the name of the author or the subject of inquiry is known in ascertaining when and by whom any specific item of work was done, whilst if the investigator only wishes to ascertain what original work has been carried out in almost any department of physiological knowledge during the last quarter of a century in this country he still has the means at his disposal in the pages of this index. It is conveniently divided into three parts. In one the names of the authors are arranged in alphabetical order, and a short title of the several papers written by each author is appended with the date and the volume and page of the journal in which they are to be found. In a second part, distinguished by a different-coloured paper, the contents of each volume are given, together with the full title of the articles; cross references enable the date of publication to be readily seen. In a third part or index proper the contents of the 25 volumes are arranged in accordance with the subjects of the several articles. This part is the one that will prove most generally useful. The scheme that has been adopted was devised by Professor J. N. Langley who is responsible for its execution, but due praise must be given to Miss L. J. Naylor, to whom has fallen the task of corresponding with authors (who have in many instances given *précis* of their papers) and of copying the slips. A glance through the headings of some of the more important subjects will show that the preparation of the index must have involved much time, care, and consideration, and it really affords an excellent idea of the recent work that has been done in that particular direction. Thus under the heading "Heart" there are references to no less than 112 articles, under the heading "Kidney and Urine" to upwards of 60, and under that of "Brain and Spinal Cord" to about 80. The task of the searcher is lightened by the references being arranged according to certain subdivisions which are given immediately under the heading. Thus under the heading "Heart" the succeeding references are disposed under the subdivisions: (*a*) Electrical Phenomena; (*b*) Mammals (*a*) Sounds, (*β*) Nerves and their Action, (*γ*) General; (*c*) Birds and Fish; (*d*) Reptiles; (*e*) Amphibia (*a*) Action of Chemical Substances, Circulating Fluids, (*β*) General; (*f*) Invertebrates; (*g*) Cardiac Muscle. In conclusion, we may remark that the work is indispensable to those who possess the several volumes of the *Journal of Physiology*, and will be found extremely useful by all who wish to have a ready means of following recent advances in physiological knowledge.

Man: a Monthly Journal of Anthropological Science. Published under the direction of the Anthropological Institute of Great Britain and Ireland.—The March number of this journal contains among its original articles notes from Australia, Madras, New Zealand, Lord Howe's Island, and the New Hebrides. Mr. Henry Balfour describes and figures a peculiar form of beaked boomerang in which the beak is not, as is usual, continuous in structure with the shaft but is formed of a separate piece of wood fixed to the shaft with gum. Mr. F. Fawcett gives some interesting notes upon the Dimbs of Jeypore, an Outcaste Jungle People of the Vizagapatam District of the Madras Presidency. From New Zealand comes a curious note from Mr. J. Edge-Partington upon a Matuatonga or Sacred Image of the Maori People. We are glad to see that those who are not members of the Anthropological Institute can obtain this journal for the sum of 10*s*. per annum, for the subjects therein dealt with are of especial interest in these modern days when old customs and nations are fast passing away.

New Inventions.

AN ELECTRICALLY-LIGHTED BRUNTON'S AURISCOPE.

THIS adaptation has been made for me and at my suggestion by Messrs. Arnold and Sons, Smithfield, London, E.C. It will be found useful for examining the tympana and ossicles without the necessity, always troublesome alike to medical man and patient, of adjusting the auriscope and posing the patient's head into such a position that the daylight or lamp-light shall be fully thrown into the reflecting trumpet of the instruments. Moreover, it is an adaptation to a cheap form of a long-lasting, dry cell battery, with no acid to spill or corrode, that has lately been put upon the market and has found a large sale among my *confrères*. Fig. 1 shows a silver-plated Brunton's auriscope (O) with its reflecting trumpet (T). Fig. 2 shows the lamp fixed by two or three turns of a screw to its wooden holder (H) and connected to the battery (B) by means of silk-covered insulated wires (W) disappearing into the cells through the hole X, (Figs. 1 and 2). My adaptation consists of a flat ebonite disc (D E), carrying a small electric lamp similar to, and of the same power as, the before-mentioned one, or as described below; the latter may be used for both holder and auriscope. The disc carrying its lamp is easily and quickly adjustable by means of two claws and a single screw (S) to the rim of the reflecting trumpet of any ordinary-sized Brunton's auriscope, and is shown in position by shaded lines in Fig. 1. This renders the instrument self-lighted. To switch on the electric light press down the push (P). As the life of the dry cells when in use is limited, like that of the lamp itself, to so many hours—viz., of continual light—the push is important from an economical point of view, so that neither battery nor lamp (but especially the former, having the shorter comparative term of existence) may be used for longer than is actually necessary. The push, indeed need not be pressed down until the speculum of the auriscope (S P, Fig. 1) is in

the meatus auditorius, and it can be immediately released when the inspection of the tympanum is over. For those who already possess one of the batteries in question with its holder, lamp, and wires, the holder can by my arrangement be easily and quickly detached from the battery and the ebonite disc carrying its own lamp as easily and quickly substituted for it. The connecting arrangement is shown at C, Fig. 2, and is such that the ends of the wire from the battery can never touch each other, causing the battery to

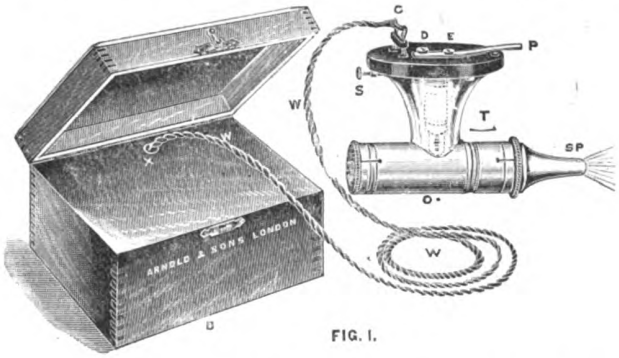

FIG. 1.

expend itself when not in use and so to be useless just at the moment when required—a vexatious occurrence which those who have used electric batteries may probably at one time or the other have experienced. But for greater convenience, although at an extra but small cost for the wires, it will be found better to have a battery with its own wires connected up to the disc. This connexion is made by a similar method to that already described and is as easily and quickly detachable from it. It is shown at C (Fig. 1) I have had the wires made about 30 inches long so that the auriscope may

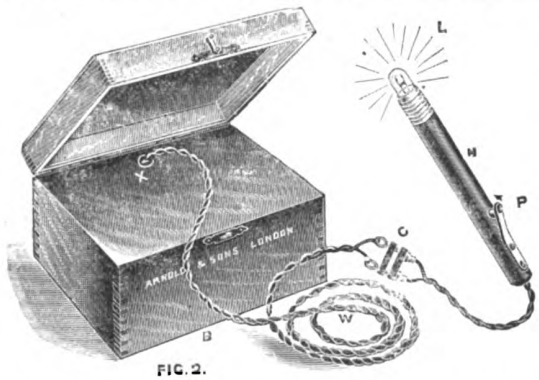

FIG. 2.

easily reach the ear of the patient when the battery is placed on a table close at hand. If it be thought desirable to have only one lamp for both holder and auriscope the lamp can be unscrewed from its holder and screwed into the auriscope disc, a similar-sized socket being on both holder and disc, and in each case two or three turns of a screw will hold the lamp in its place and connect it up at the same time. The lamps are, however, supplied separate very cheaply. The battery, disc, and lamp, without holder, can also be obtained from Messrs. Arnold and Sons.

Tottenham, N. GEORGE H. VOS, M.B. Cantab.

SMALL-POX AND VACCINATION IN PARIS.

(FROM A CORRESPONDENT.)

IN *La Presse Médicale* of Feb. 23rd, Dr. Roger, who has for some years had charge of the Isolation Hospital wards at Aubervilliers, publishes an interesting article explaining why the present epidemic of small-pox is not yet over. In this English readers will find much to reconcile them to the means taken in England to oppose such an epidemic as compared with those in France, where science and her dictates are supposed to reign supreme. It will be seen from this article that it is doubtful if vaccination is more thorough in France than in England, and that it is certain that the isolation practised in the former country is much more imperfect and unsatisfactory than in the latter. Dr. Roger openly states that the foreigners who visited his wards in this so-called "temporary" isolation hospital—it is 15 years since its construction—declared that they had never seen such a defective organisation, and he protests against the necessity of receiving in such wards patients who ought to get well, who are generally youthful and of good constitution, and valuable members of the State.

In 1898 there were only two cases of small-pox in Paris, and from June of that year to Dec. 25th, 1899—a period of 18 months—there was not a single case. In January, 1900, eight cases were received into the isolation hospital, and the year 1900 saw over 900 entries. Dr. Roger points out that vaccination and revaccination have been incomplete either from negligence or from prejudice or because of previous unsuccessful vaccination. Facts have convinced him that vaccination confers but a temporary immunity and that it may sometimes only guarantee that the attack shall be a slight one. Thus one of his male nurses who had been well vaccinated took small-pox a year later. A great number of cases had also been unsuccessfully vaccinated one or two months before and Dr. Roger therefore recommends vaccination every 10 years, but if an epidemic should break out he insists upon immediate and universal re-vaccination.

Vaccination is only compulsory in France in the sense that a certificate is required upon many occasions—for instance, during military service, on entrance into schools, and in administrations of public services and offices. Though carried out on a large scale, therefore, it is not obligatory or universal and the isolation devised is highly imperfect and illusory. Until recently the wooden wards were inclosed only by a low railing which the patients easily scaled on their way to a neighbouring tavern or through which the friends of the patients conversed and handed parcels, &c. During the last three months the palings have been improved and two policemen guarantee night and day the isolation of the small-pox cases. It is almost incredible that the patients are allowed to write letters to their friends outside—letters that it has been found impossible to disinfect—but the law allows it. Hardly less credible is the fact that patients need not remain in hospital till the scales are all fallen; on the contrary, many leave as soon as they feel well enough or as soon as the pustules no longer make them objects of disgust. Dr. Roger states that almost all the female patients leave in from 20 to 25 days. What wonder that the epidemic persists when such patients return home shedding their infected epithelium in their dwellings, in the streets, in the cars and omnibuses, and until recently actually in cabs which they were allowed to call. For the last three months, it is true, a patient who insists upon leaving before he is cured must do so in an ambulance. This is the extreme limit of the power of the law. In one of Dr. Roger's cases the kindly *concierge* nursed a patient in the garret until she finally succeeded in giving the disease to most of the other lodgers. In another case the *concierge* himself took the disease and remained in his *loge* until some weeks later his wife also was attacked. The man then resumed his duties, carrying the letters, cleaning the staircase, receiving the visitors, and scattering his epithelial scales broadcast. One *concierge* refused to admit the accuracy of Dr. Roger's diagnosis and returned home to take care of the eruption which, she said, came "from the blood." It is certain that some cases are undiagnosed. Many medical men in practice have never seen a case of small-pox, for the happy reason that as it exists but at intervals they only know it theoretically. Courses of instruction in the specific fevers should undoubtedly be compulsory for students of medicine.

The lamentable state of things, therefore, in Paris as elsewhere, is that we know how to suppress small-pox, but we do not put our knowledge into effect. Compulsory vaccination and re-vaccination and an effective isolation of the infected—*ibi salus est*.

THE LANCET.

LONDON: SATURDAY, MARCH 23, 1901.

The Remuneration of Medical Witnesses.

THE attitude of the Home Office towards the question of the fees to medical witnesses in criminal courts and before coroners continues to be one of indifference veiled under more or less polite platitudes. In replying to a question on the subject put to him by Mr. W. F. LAWRENCE, M.P., the other day, Mr. RITCHIE said: "I do not think the fees of medical witnesses can be touched without dealing at the same time with those of other witnesses, and this I am not prepared to do in view of the largely increased cost of prosecutions which might be the result of such a revision of the present scale." Mr. RITCHIE'S predecessor, Sir MATTHEW WHITE RIDLEY, frankly refused on two occasions to receive deputations on the subject, and Sir MATTHEW WHITE RIDLEY'S predecessor, Mr. ASQUITH, in answering a deputation in 1895, said, among other things: "The same remark [i.e., that the remuneration of medical witnesses is inadequate] might be applied with a greater or less degree of truth to every item in the scale as applied to a professional witness. If it were true that it was a condition of the medical profession to attend courts in a sense which could not be said of other witnesses, then the logical conclusion to his mind was not that this scale of remuneration should be altered," but, he went on to suggest, that special arrangements should be made between police surgeons and watch committees.

In applying the opprobrious term "platitudes" to such replies as these we venture to suggest that they are not the result of the individual reflections of the gentlemen who made them, but are rather in the nature of stock objections filed for the use of Home Secretaries by permanent officials unwilling to sanction the amendment of a long-standing grievance. Mr. RITCHIE says that he does not think the fees of medical witnesses can be touched without dealing with those of other witnesses, while Mr. ASQUITH clearly did not see, or refused to admit, that it was a condition of the medical profession to attend courts in a sense in which other witnesses could not be said to attend them. Mr. RITCHIE went further by offering speculative conjectures as to the large increase of costs if the fees of other witnesses as well as of members of the medical profession were augmented. If by other witnesses Mr. RITCHIE meant other professional witnesses, following the line of argument adopted by Mr. ASQUITH, we disagree with him. It is, however, a matter in which a return could easily be made that would put the point beyond question, and we should like to see by how much per cent. the average cost of prosecutions in England and Wales would be increased by the adoption of a similar scale to that prevailing in Scotland or in Ireland. English Home Secretaries ignore the fact that medical witnesses are remunerated on far higher scales both in Scotland and in Ireland without apparently undue burdens being cast upon the funds made liable. With regard to the theory, held apparently both by Mr. RITCHIE and by Mr. ASQUITH, that medical men are not members of a profession peculiarly situated as regards giving evidence we do not feel disposed to discuss at length what most of our readers will agree is obvious. We only point out that in the prosecution of nearly all crimes of violence, and of nearly all sexual crimes, medical witnesses are called and that these are not always police surgeons. They are frequently medical men who are witnesses because they could not, without incurring the charge of inhumanity, refuse to render aid to persons injured for whom their aid was sought, although to render it meant to incur the pecuniary loss involved in attending the criminal courts.

We would further point out that the attendance of medical witnesses is a matter of which the statistical returns are obtainable and that the statistics would certainly show that medical witnesses attend courts as witnesses of no other profession do, while we may ask what class of witnesses there is that is now urging that its members should be treated differently, or what class of witnesses, in the opinion of the Home Office, would combine to protest if the claims of medical witnesses were dealt with separately. The fact that the British Medical Association and the United Kingdom Police Surgeons' Association have formed a joint committee to approach the Home Office in the matter is not required to prove that the scale of remuneration for medical witnesses is insufficient. The Home Secretaries whom we have quoted do not deny that. The fact that these organisations have formed such a committee for such a purpose, in the absence of other organisations representing other professions, is evidence that the insufficiency of remuneration for professional witnesses affects medical men in a peculiar degree. We are thus led to the conclusion that the grievances of medical witnesses could be remedied without injustice to others, and that Mr. RITCHIE'S statement of opinion to the contrary would not be easy to support by any logical argument.

Alcoholism and Insanity in Scotland.

DR. T. S. CLOUSTON, the medical superintendent of the Royal Edinburgh Asylum, Morningside, in his recent annual report to the Edinburgh corporation has included some statistics on an increase in alcoholic insanity in Scotland which have somewhat startled Scotland. The figures constitute another valuable contribution from our profession to the solid arguments on which any successful effort to procure effective legislation for promoting the sobriety of the nation must be based. There have been many differences of opinion as to the exact rôle of alcohol in pathology, even in regard to Scotland, where such a large field exists for clinical and post-mortem study of the facts. To judge from the extent to which whisky, the almost universal Scotch drink, has lately been introduced into England, the observer might think that

it was as innocent as new milk. And certainly some forms of disease which might be looked for from its use in Scotland are comparatively rare—cirrhosis, for example, and to some extent gout and alcoholic neuritis. We really want from the pathologists of Scotland a good account of the pathological effects of whisky as a national drink. On one point there seems little doubt—that is, its injurious effect on the brain. There is a general consensus of opinion on this point.

Our immediate purpose is to direct attention to Dr. CLOUSTON'S report on the rapid and striking increase during 1900 of insanity among the working classes of Scotland, particularly in Edinburgh, and to his conviction that it was due to the freer use of alcohol as a part of the high prosperity of the year. Dr. CLOUSTON says that "he never had experience of anything approaching this before and that he would fail in his duty if, seeing more of the terrible effects of excessive alcohol drinking in destroying human reason and self-control than almost anyone else in Scotland, he did not strongly draw attention to a fact so disgraceful to them as a community." We should equally fail in our duty if we did not note Dr. CLOUSTON'S facts. Practically they amount to this. The year was a record one for admissions. The increase was entirely in rate-paid cases, the numbers of which prevented Dr. CLOUSTON from admitting private patients at a low rate of board, which, he says, constitutes a great hardship to the friends of patients whose means are small—a class, we may add, entitled to the greatest sympathy in every community. Of course there are not wanting in Scotland able apologists for alcohol who are not willing to admit Dr. CLOUSTON'S conclusions. It is easy to suggest flaws in the chain of evidence that associates this startling increase of pauper insanity with an increase in the consumption of alcohol. The complex causation of insanity in any individual case can always be insisted on. And it must be admitted that prosperity was not the only note of the year 1900. It was a year of war and of much adversity in war in which Scotland was deeply and not dishonourably concerned. But no criticism of this sort will seriously shake the effect of the report of Dr. CLOUSTON, who has taken all these other possible causes into consideration, and who has come deliberately to the conclusion that in a fourth of his cases in excess of the average the determining cause was alcohol. The conclusion coincides too closely with other medical evidence to be open seriously to doubt. There is but one consolatory fact in such a conclusion. The situation is discreditable to the intellect and the morals of religious and educated nations such as England and Scotland, but it is remediable, and removable to a very great extent, if the legislature will consent to give its help to social and political reformers.

The immediate cause of the overcrowding of the Royal Edinburgh Asylum during 1900 was the great rush of rate-paid cases. They numbered 400, or 20·5 per cent. over the average of the past five years. After descanting on the inconvenience of such an increase and considering the complex causation of it, Dr. CLOUSTON says that "he could not get over the conclusion that the excessive use of alcoholic stimulants during times of brisk trade and high wages had to a large extent been the cause of the undue amount of mental disease which they had been called on to treat last year, constituting about a quarter of the whole admissions in whom drink was assigned as either the sole or a contributory cause." As regards the admissions of men alone 81, or about one third, were alcoholics. Dr. CLOUSTON does not think seriously of the general increase of mental disease in Scotland, at least in the classes from which private patients come. In the 20 years ending 1899 the increase of such patients amounted to only 378, an increase of 16 patients a year, in a population of 4,200,000, whereas the rate-paid class of patients increased in the aggregate 2545, or at the rate of 124 a year. It is sad to have to notice that the greatest increase is in the northern and Highland counties where life is solitary. The increase of pauper insanity in the Highlands amounted to 17 per 100,000 inhabitants, in the rest of Scotland to 9½, and in Edinburgh to only 3. The blue books show that in Scotland, as elsewhere, the aged suffering from any brain failure are sent with increasing frequency to asylums, but it may be a matter of just pride to Scotchmen that they support their insane relations without letting them fall on the rates in twice the proportion of Englishmen, and in over three times that of Irishmen.

Dr. CLOUSTON does not preach voluntary teetotalism or legal prohibition or any impracticable doctrines. He simply aims at reducing the disease produced by alcohol, acting on the lines of Dr. SNOW and Sir JOHN SIMON when they pointed out that the causes of preventable disease lay in contaminated water. Insanity and general physical degeneration call as loudly for repression as does cholera. The nation was never more interested in ascertaining and removing the causes of such evils than it is to-day. The removal of preventable alcoholic disease is as much a duty of statesmen and politicians as it is of philanthropists, on whom some politicians would throw the whole work of dealing with this class of disease. The State has already acknowledged responsibility. The whole system of licensing laws is such an acknowledgment. A more recent one is a Bill contemplating the reform of the intemperate, to which measure Lord SALISBURY has just given his adherence. Surely our statesmen will not argue that they do all they can to stop the enlarging mortality from alcohol pointed out to them by the medical profession and the Registrar-General when they make ineffective efforts to reform habitual drunkards and leave untouched the laws which acilitate the creation of drunkards. The legislation in behalf of habitual drunkards is little better than a delusion. There are at least a score of preventive measures—apart altogether from the thorny question of compensation and the reduction in the number of public-houses—of urgent importance in regard to which public opinion is ripe for legislation. We venture to hope that Dr. CLOUSTON is a little too despairing of the prospects of receiving help from this Government. Mr. RITCHIE'S last speech is promising, and we hope that performance is meant. If the result does not meet public expectation we agree with Dr. CLOUSTON in thinking that a "big reckoning" may overtake the present administration when the cessation of war enables men to realise the destruction of life and morals which is going on insidiously among men, women, and children as a result of the present proportions of the drink traffic.

The Health of Board School Children.

IN an address, a copy of which we have received, delivered at the Durham College of Science and entitled "Health in the School," Dr. THOMAS OLIVER has raised many points of general interest and has made some suggestions of practical utility. The subject is most conveniently divisible into two principal sections—the hygiene of the school, the board school or the national school as the case may be, and the health of its inmates. Under the former heading attention is directed to the marked improvement in arrangement and construction which distinguishes the board schools of recent origin from those built on the passing of the Elementary Education Act in 1870. Exception is taken, however, to schools of this class in general in respect of certain obvious defects. These include a frequent insufficiency of playing-ground around the building and the absence of definite and well-considered method in the internal arrangements for heating and ventilation. Both of these latter necessities have been provided for with the diversity of plan which belongs to an experimental epoch and, according to Dr. OLIVER, without conspicuous success. He draws attention to the fact that while each inmate in a factory is entitled to 250 cubic feet of air space the Education Department is content with a minimum of 80 cubic feet. He further insists upon the importance of removing impure air as essential to the proper aeration of class-rooms—a point which he shows has received too little attention. For this purpose he prefers the system of extraction by a revolving fan to every other method. The ingress of air he considers is best arranged where gratings in the vicinity of hot-water pipes are made to act as inlets. No form of heating apparatus commends itself to his judgment so much as the system of warming by hot-water pipes. Closely connected with the ventilation is the cleansing of class-rooms. Mere dry sweeping is insufficient for this purpose, inasmuch as it usually does little more than raise dust without disposing of it. Some useful hints on this subject have not been omitted.

Passing on to the physical condition of the children attending the free elementary schools, Dr. OLIVER discusses at considerable length the disorders common among children reared in poor and insanitary homes—such as general weakness, adenoids, cretinism, tuberculous glandular troubles, and ophthalmia—and the means appropriate to their prevention and cure. Most significant are his observations on the effects of over-pressure and fatigue. His views on this subject are quite in accordance with those of his fellow-countrymen, medical and non-medical, who have given their attention to it. He quotes, moreover, the experience of a German authority, Dr. KEMSIES, who finds that among his pupils the best work is done during the early days of each week and the early hours of each day. Two hours' work at one time suffice to induce fatigue and should therefore, he maintains, be followed by an interval of recreation. Another constant result of overwork in school is defective eyesight. The fact has long been recognised, but sufficient attention has not been given to its real significance. Dr. OLIVER'S own statistics on this subject are highly instructive. They show a notable excess of deficiency among girls as compared with boys, and among senior as compared with junior children. In 16 schools examined in Newcastle the average percentage of boys affected was 4·2, that of girls 6·3. This defect he attributes, and probably with justice, to imperfect lighting, over-pressure, and the teaching of fine needlework at too early an age. German observations provide exactly similar data. In addition, COHN of Breslau noted a marked excess of myopia among children attending town schools over that among village school-children. Dr. FERDINANDS of Aberdeen made the same observation after examining upwards of 3000 pupils. The facts seem to be uncontrovertible. They show clearly that a certain proportion of children in elementary schools, for the most part children of poor parents, have myopic or otherwise defective sight, that this deficiency increases with the duration of school life, and that it is most noticeable in town schools where the pressure of work is known to be highest and where the general health conditions are far inferior to those in country schools. Where are we to look for a remedy? Dr. OLIVER is in favour of instituting inspection by an ophthalmic surgeon in the case of such defective children. He admits, however, a probable difficulty in inducing the Board of Education to sanction the outlay. We see no reason why teachers should not be incidentally useful in this way. They might easily be instructed to note generally any evident defects of hearing or vision or obvious and specified failures of health. This done, parents could be warned to seek medical advice. The primary responsibility in such a case is with the parent and we consider that it is most judicious not to deprive him of it but to encourage him to use it. Such an arrangement, however, does not touch the subject of work-pressure, and this certainly ought to be lightened wherever it can be. A shortening of hours is, perhaps, not necessary, and if not needed it is not desirable. A redistribution, however, might be advantageous. At present school work is so distributed that it drags on through the greater part of a day. We are not at all clear that the work would not be better done and the interests of health be better served if the long midday break were dispensed with, if the school hours were grouped together with short intervals of recreation, and if the work were finished by, say two o'clock in the afternoon.

We have said nothing of the position of teachers from the medical standpoint, but they have not been overlooked by Dr. OLIVER in his address. The life prospect of a schoolteacher is, on the whole, good and compares favourably with that of persons engaged in other callings. Minor troubles attributable to the harassing nature of the work done and to bad ventilation and long standing are, however, prevalent. In consideration of these and on other and general grounds the plea for seats for teachers and the suggestion that no one of their number should be employed for more than a limited time in close and unhealthy neighbourhoods have our cordial approval.

Malaria in the Pacific Islands.

As we are frequently reminded, both in and out of season, some portion of the British Empire has its face ever turned towards the source of light. But we hear less frequently of the responsibilities which his fact entails in the direction

of scientific research. We possess unique facilities for the acquisition of scientific knowledge in every latitude and longitude, but pecuniary grants for scientific investigation do not figure largely in our Estimates, and the Government Bench is rarely or never harassed by questions upon the subject. There are, however, indications that a broader spirit is about to prevail—a change that is in no small degree due to the support, both moral and substantial, which the Colonial Office under Mr. CHAMBERLAIN has extended to the study of tropical diseases. In the investigation of malaria enormous strides have been made of late, but there are numerous problems still outstanding upon the solution of which the practical application of recent discoveries largely depends. Malaria undermines the health and comfort of millions of HIS MAJESTY'S subjects and further investigation may reasonably expect to receive the support of governments, of societies, and of wealthy individuals.

Dr. PATRICK MANSON has recently proposed to the Epidemiological Society of London that an expedition might well be despatched to the Pacific Islands to investigate the causes which make for the apparently capricious distribution of malaria. The presence or absence of malarial disease in any given locality depends, Dr. MANSON suggests, upon the presence or absence of its subserving mosquitoes, such presence or absence being determined by the existence of special conditions inimical to special species of mosquitoes. By way of throwing light upon this suggestion it is proposed that an expedition should be despatched to one of the Pacific Islands, as Samoa, in which malaria is at present absent. Here the investigators would set themselves to study the local mosquito, and having obtained full knowledge of its habits they would proceed to investigate the mosquito of an island in which malaria is endemic. They are then to convey the anopheles from the malarial to the non-malarial island and to endeavour there to breed the anopheles under laboratory conditions. In the aquarium thus formed there would be introduced certain plants and animals which are apparently peculiar to Samoa with the view to discover, in one or another of these, something antagonistic to the anopheles. The experiment would then be repeated under conditions as nearly natural as might be possible. Dr. MANSON hopes that by this means there may be discovered a something which is hostile to the anopheles, and which may be subsequently turned to good account by being introduced into islands and localities where malaria is endemic. The Pacific Islands are suggested by Dr. MANSON from the fact that they also afford unique opportunities for the study of filariasis and elephantiasis. In many of the islands this latter disease attacks from 20 to 50 per cent. of the population, and in others filariasis attacks from 30 to 60 per cent. But there are also small islands with populations of from 200 to 300 in which elephantiasis is alleged not to exist, while there are other islands, equally small in population, where almost every individual is affected. The vast importance of ascertaining the distribution and habits of certain species of mosquitoes has been brought home to us during the last few days by a very remarkable paper which was read at the Pan-American Congress at Havana. At this Congress, according to our New York correspondent, Surgeon WALTER REED and Assistant-Surgeons CARROLL and AGROMONTE have recorded the manner in which they claim to have proved that the mosquito belonging to the species *culex fasciatus* which abounds in Cuba is the agent instrumental in conveying yellow fever from man to man. With a heroism worthy of the cause of truth, the same spirit which animated WALTER MYERS and led to his untimely death, persons submitted themselves to be bitten by mosquitoes which had been nourished upon the blood of yellow fever patients, with the result that they were themselves attacked by the disease. Other willing subjects exposed themselves to infection from presumably infected fomites, but in spite of every effort being made to cause the clothes, &c., to act as infecting agents no success attended the efforts. The inference is that yellow fever is not thus communicated from person to person. On the dangers of such methods of investigation we need not enlarge, while the results of practical observations of this sort may be immense and culminate in the alleviation of much human suffering.

Dr. MANSON'S proposals seem well worthy of support, and even if the specific problems to which he alluded were not solved much valuable and helpful information would doubtless be forthcoming from a scientific expedition to the Pacific Islands. The members of the Epidemiological Society have, it is gratifying to learn, accepted the proposal of their President, and efforts are being made by an appeal to the Foreign Office and to the Colonial Office, to the Local Government Board, and to the more important corporations and City companies, to obtain the £2000 necessary to support the expedition. Already a generous and anonymous subscriber has promised £500 towards the scheme, and it is much to be hoped that the enterprise will not fail from lack of subsidy. As Dr. MANSON remarked in his address, "It will be strange if in a country which provides liberally for what might be called sentimental expeditions—such as the discovery of the North Pole, or for settling mere geological points of not very great practical importance, such as the determining of the process by which coral islands acquired their peculiar conformation,—it will be strange if in such a country funds cannot be provided to attempt, in the way I suggest or otherwise, the settlement of important questions affecting the life and comfort of men and the material prosperity of the country." We cordially endorse Dr. MANSON'S expression of opinion and we trust that the necessary funds will speedily be forthcoming.

Annotations.

"Ne quid nimis."

THE DINNER OF THE HUNTERIAN SOCIETY: SIR WILLIAM MACCORMAC'S SPEECH.

THE eighty-second anniversary dinner of the Hunterian Society was held on March 15th, and the event of the evening was a vigorous speech from Sir William Mac Cormac, who dealt with the efforts that have been made to cast doubt upon the sincerity of his publicly-expressed opinions on the conduct of the Royal Army Medical Corps in South Africa. According to Sir William Mac Cormac, he and Mr. Frederick Treves did

not attach much importance to the criticism which had been levelled at their utterances as their critics were without any proper conception of the requirements of war. He himself had all along adhered to the opinion that the action of the Royal Army Medical Corps had been extraordinarily good, and they had now come forth from the inquiry with the consciousness that despite circumstances of extreme difficulty and great stress there had been no scandal and no serious shortcomings. Never before in the history of the country had there been a war of the kind and on no previous occasion had the army medical service been subjected to such strain and hardship. Considering how few the Royal Army Medical Corps were in point of numbers he considered that they had done extremely well. They were only 800 strong instead of 1200 as they should have been, but they had fulfilled all requirements notwithstanding the fact that they were intended only to serve two army corps and had to do duty for six. No one could dispute that it was a matter for sincere congratulation that the medical men had performed this remarkable feat without a complete breakdown. He regretted to say that it had been suggested in certain quarters that the officers of the corps had failed in the discharge of their duty. It was very hard that these men should be deprived of the sympathy of those in authority when they had done their very best under the most adverse circumstances, in many instances suffering death not merely in action but in the daily discharge of duty. The Royal Army Medical Corps might be swept away altogether, or it might be retained, when it must be placed on a much better footing than it was now and the officers must be raised to a higher status. The head of the Army Medical Service was not accorded the high position which he certainly ought to occupy and which in other countries such an officer did occupy. From his own personal knowledge he knew that the chief of the German Army Medical Corps held a very different position to that granted to the officer of corresponding rank in the British army. In Germany the chief of the Army Medical Corps was respected and his word was law, whereas in this country the position of the Director-General of the Army Medical Service was quite a subordinate one, and not only was this the case in regard to his pay but it was also the fact in respect to his status. If the country wished to have a proper army medical service it must be accorded a certain amount of sympathy and it must have its proper status and suitable pay. Sir William Mac Cormac concluded his remarkable vindication of the over-worked and maligned medical officers at the seat of war by pointing out that it was not the first time that he had had actual experience of war and that he could affirm that he had never seen sick and wounded men better cared for than in the present campaign. That conclusion was endorsed by the report of the Royal Commission instituted to inquire into the matter.

A JUDGE UPON THE HOUSING OF THE WORKING CLASSES.

MR. JUSTICE GRANTHAM, who has, we are sorry to learn, been indisposed while on circuit, has relieved the monotony of life in the judge's lodgings at Lewes by writing to the *Times* on the problem of the housing of the London poor. His remedy is of the rough-and-ready order, and if he has meditated profoundly on the means of carrying it out he has not made them public. He believes that London should be a mart rather than a manufactory of merchandise, and that if the manufacturing element were eliminated the difficulty would be at an end. He says, to quote his own words, "Drive out all manufactories and their workpeople into suitable places by the river and elsewhere, and the spaces left will enable you to house most of the workpeople necessary for carrying on the business of a commercial and residential town." Amongst other instances of manufactures carried on in London which might be carried on either just beyond its limits or still further off he mentions certain gasworks and the manufactories of Messrs. Maple, Messrs. Shoolbred, and Messrs. Doulton. Who are to carry out the work of expulsion he does not suggest. Presumably Parliament, as it would certainly exceed the powers of the County Council. As to how London would reconcile itself to the measure he does not speculate, nor does he mention that as manufacturers must almost necessarily carry on their work where it pays them best to do so they will need substantial compensation for such disturbance, while the removal of the big manufacturers and their workpeople would create space by removing highly rated buildings and the prosperous artisans who, though they need better housing, are not accountable for the worst part of London's over-crowding. If Mr. Justice Grantham were a fairy with a wand to carry out his own reform, and we could wake up to find London a Utopia devoted only to residence and the distribution of articles manufactured elsewhere, we should find London considerably diminished in importance. It would offer a less substantial objective to an enemy's attack in the event of war with a European Power, but it would lose its tremendous and pre-eminent position in the world in time of peace. At the same time all suggestions for solving the housing problem are interesting, and that of Mr. Justice Grantham has originality to recommend it, while it cannot be said to be of the tinkering order. If carried out it would at least effect its object, and it may contain the germ of a less drastic but more practicable measure.

THE WRONG MEDICINE AND ITS RESULTS.

AN action recently brought with success against a firm of druggists at Glasgow illustrates the dangers which may arise where the business of dispensing drugs is not carried out with the greatest possible care in all its departments. The pursuer, or to use the terminology of our own courts, the plaintiff, a commission-agent in the boot trade, took two prescriptions to the defendants' shop to be made up, one for a potion and the other for an ointment. Later in the day he sent a messenger to fetch them, and on the lad returning with one bottle only sent him again to ask for the ointment and the prescriptions. The druggists seem to have said that they had no ointment and no prescriptions to deliver, and the request for these, which was repeated a second time, does not seem to have excited any anxiety in their minds as to a possible mistake. On the other hand, the customer seems to have assumed that the bottle he had received contained an instalment, at all events, of what he had ordered, for he took some of the mixture, merely tearing off enough of the paper wrapper to enable him to extract the cork. Had he torn off more he would have found an ordinary blue-glass fluted bottle such as is used for poisons, with a label informing him that it contained "Poison Not to be Taken," and further that it was intended for a Mrs. Robinson, he being Mr. Robertson. A confusion between the two names had no doubt led to the initial error of the wrong parcel being handed over the counter and up to this point the mistake of the druggists, though serious and avoidable, was one which might occur in such circumstances without there being great negligence on their part. Their subsequent behaviour, however, cannot be defended. Mr. Robertson went at once to the shop and asked if that which he had drunk and which had irritated his throat considerably had been that which he was intended to drink. The error was then discovered, but the course adopted by those to whom he made his complaint was not calculated to mitigate the danger which had arisen. Being aware of the

contents of the bottle intended for Mrs. Robinson, the defendants' assistant knew that Mr. Robertson had swallowed a mixture containing chloroform, belladonna, and aconite. He appears to have inferred that the quantity taken was small, mainly from Mr. Robertson being still alive; and instead of sending for a medical man without delay the assistant was content with administering an emollient and some jujubes to allay the burning sensations of the throat. Mr. Robertson, temporarily relieved and reassured, went home to Pollokshields, but became very ill by the time he reached his house. He was then medically attended, with the result that he ultimately recovered, but only after he had been away from his business for several weeks. In defending the action brought against them the druggists made the most of the conduct of the plaintiff in not unwrapping the bottle sent to him and discovering that he had received a parcel that was not meant for him, but the jury found against them with £700 damages. This is a large sum, and if the firm were being fined simply as the result of an assistant handing the wrong parcel to a possibly inarticulate boy we might consider it too large. But the Lord Justice-Clerk, in his summing-up, took a view, with which we agree, that the defendants, or their assistants, for whose carelessness they are answerable, had two opportunities of correcting their mistake and would not avail themselves of them. When the plaintiff sent to ask for his prescriptions and his ointment they ought to have suspected an error, while they had a further chance of minimising the result of their previous lapse when the victim visited their shop and stated that he had drunk what might or might not have been a fatal dose of a poisonous compound. With the greatest care and with constant supervision it is difficult to eliminate mistakes from the conduct of any business, but in the dispensing of drugs, in which a mistake may lead to terrible and tragic consequences, all concerned should be eternally on the alert to detect the possibility of accident. The plaintiff is not likely to drink medicine again without taking the precaution of unwrapping the bottle, and the fact that out of his contributory carelessness came £700 damages will not serve to conceal the fact that he came within an ace of death. The most reckless patient should be aware that the amount of the dose to be taken is of importance and that the label on the bottle usually gives directions upon the subject which he should study and obey. Had Mr. Robertson done this he would have been spared an experience which may have been dear even at £700.

THE ELIMINATION OF ARSENIC THROUGH THE HAIR.

WE publish an original article this week in which the authors—Mr. Edmund Knecht, Ph.D., F.I.C., and Mr. W. F. Dearden, M.R.C.S. Eng., L.R.C.P. Lond.—show conclusively that arsenic occurs in easily detectable quantity in the hair of persons who have been taking the drug either medicinally or accidentally as in the case of beer. The observation is of the utmost importance in affording a decided aid to the diagnosis of arsenical poisoning. As Mr. Knecht and Mr. Dearden point out, M. Gautier of Paris, in discussing the part played by arsenic in the animal organism, referred to the function normally exercised by hair as a means of eliminating arsenic from the system. Other workers have also referred to the fact of arsenic having been detected in the hair. Dr. J. Reid of Redhill, for example, writes to us in a letter dated Jan. 12th, 1901, expressing his surprise that no complete necropsy has been made in connexion with the beer-poisoning epidemic, although he points out that in the case of a rabbit suffering from chronic arsenical poisoning he has seen the liver fatty in one lobe, the fatty portion being marked out from the sound portion by a straight vertical line. But incidentally he describes an easy and rapid test for arsenic, recommending for the purpose the examination of the hair by means of an ammonia copper solution containing an excess of the precipitated copper oxide. In patients taking small doses the medulla of the hair will remain unchanged so far as half an inch objective is concerned, but when viewed by one-sixth inch objective the small green particles of arsenite of copper are seen appearing as green granules without definite shape or form. Dr. Reid was thus led to think that this simple test might prove useful forensically. His observations are now completely confirmed by Mr. Knecht and Mr. Dearden, who, however, have successfully employed not only a method of detection, but a method of estimation. Thus in healthy patients the quantity of arsenic found was too minute to be estimated in one gramme of substance, but in a patient who was taking the drug medicinally the hair was found to contain arsenic in the proportion of 0·3 in 10,000. One of the patients who had been drinking arsenical beer had present in his hair the same proportion of arsenic, whilst another showed as much as one part of arsenic in 10,000. The method employed for the estimation of arsenic consisted in first destroying the hair by fuming nitric acid, then dissipating the excess of nitric acid, after which the product is transferred to the Marsh apparatus. The fate of arsenic in the economy is thus shown to enter a new and interesting phase. It would be of great importance and interest to determine whether when arsenic is administered as an organic combination, such as cacodyl, the drug is eliminated in the same way. It was, no doubt, the instructive study of organo-arsenic derivatives by M. Gautier which led him to refer to the function normally exercised by hair as a means of eliminating this element from the system. There is abundant evidence now to show that the fate of arsenic in the body is partly in the hair, and this fact cannot but be of the utmost importance in medicine, especially in toxicology.

THE PREVENTION OF TUBERCULOSIS.

As a result of the deputation from the Society for the Prevention and Cure of Consumption in the county of Durham, the Sunderland Town Council on March 13th passed the following recommendations of the Health Committee:—

That a fee of 2*s*. 6*d*. be paid to medical practitioners in the borough who notify to the Health Office those cases of consumption of the lungs in the borough in which there is expectoration or discharge containing tubercle bacilli, such fee only to be paid once in the case of each patient. This arrangement to be in force for one year on trial.

That the council enter into a contract for one year, from the beginning of May next, with the Society for the Prevention and Cure of Consumption in the county of Durham for the use of two beds in the county sanatorium at Stanhope by the payment of £75 per bed for that period. Such beds to be reserved for the sole use of poor patients from this borough in the early stages of the disease.

Alderman Harrison, the chairman of the Health Committee, remarked that if they got early information of the existence of the disease at any place the officers would endeavour to prevent its spread by attending to the surroundings of the house and making them unfavourable for its development. When they got into a system of compulsory notification of cases of consumption they would go a step further in the prevention of the spread of the disease. He declared that the open-air cure had passed the experimental stage and was now a success. By a notice placed inside the electric tramcars persons have been earnestly requested not to spit in or on the cars in Sunderland, and for some years past the corporation have had suspected sputum gratuitously tested for tubercle bacilli, have offered the free disinfection of the rooms of consumptives, have distributed

leaflets on the prevention of consumption, and have also granted certificates to dairy farmers who keep sanitary byres and all of whose cows have been proved free from tuberculosis under the tuberculin test.

CHILDREN AND THE DRINK TRADE.

THOSE who wish to study the question of the injury inflicted by the drink traffic on the child-life of the nation would do well to possess themselves of a pamphlet on the subject published by Mr. Brimley Johnson at 3, York-buildings, Adelphi, W.C. The preface is written by the Archbishop of Canterbury. The book contains some startling facts bearing on child-drunkenness and alcoholic diseases in children. The third part deals with the prohibition of sale to children and is worthy of special study in connexion with the introduction of a Bill in Parliament for this purpose. The practice of other countries is quoted and the reader is left with the impression that sixteen years is the lowest age at which children should be allowed to buy drink. The principle of parental authority has not been allowed absolute sway in our legislation where the vital and moral interests of the child are at stake, and all allow that they are terribly at stake in this question. Much of the injury to children through alcohol comes from ignorance, as when a mother gives beer and gin to her child while taking the same herself. There is an element of unselfishness in the habit of giving the child "a drop," but thoughtlessness and ignorance sadly predominate. The large majority by which the second reading of the Bill was carried on Wednesday is a clear proof, for the guidance of the Government, as to the feeling of all parties on this subject.

THE SIEGE OF THE LEGATIONS AT PEKING: A FRENCH SURGEON'S WORK AND VIEWS.

SURGEON-MAJOR MATIGNON of the French army, who volunteered for duty at Peking when the situation became grave, has a short paper in the *Archives de Médecine et de Pharmacie Militaires* for March describing his experiences during the siege last summer. "The events that took place at Peking from June 20th to August 15th, 1900, have this peculiarity," he says in his exordium, "that a handful of men were taken by surprise when destitute of everything, or pretty nearly so, and found themselves compelled to organise a defensible front with a perimeter of three and a half kilometres against a well-armed and well-victualled enemy 30 times as numerous as they were. A few French, German, English, American, Austrian, Italian, Japanese, and Russian sailors formed a little body of 400 rifles, to whom 50 volunteers of all nationalities joined themselves." When the Boxers made their unexpected onslaught the British Legation became a refuge-general where 800 Europeans—150 of them being women and children—sought shelter. It was here that a small hospital was improvised and to it the wounded from the outposts by which the legation was covered were carried. These outposts, three in number, were established (1) to the south-east in the French and German Legations; (2) to the north-east in a large park, where the defenders were the Japanese and the Italians; and (3) to the south-west in the Russian and American Legations. Surgeon-Major Matignon had charge of the first, being assisted by a German hospital orderly who "thoroughly understood his work and was in possession of a dressing-bag." Throughout the siege, notwithstanding the necessarily defective hygienic arrangements, the bad quality of the water, of which the men, owing to the excessive heat, were forced to drink enormous quantities unfiltered and unboiled, and an almost entirely flesh diet (for 55 days horse meat was alone available), the little garrison of 90 men all told had no sick. The enemy's efforts were for the most part expended upon four chief points, and to these whenever an attack commenced Surgeon-Major Matignon used to hurry with his game-bag full of surgical necessaries. The French and Austrian detachments having arrived without any medical *personnel* he had absolutely no one to help him on these occasions, but was compelled to do everything with his own hands. As soon as a man was wounded he dressed him on the spot as well as he could and sent him back to his work. Their numbers were too small to admit of the ranks being even temporarily depleted, but Surgeon-Major Matignon adds that "not one of them [the wounded], even those who were seriously injured about the head, made the slightest difficulty about resuming his service." The Chinese kept up an incessant shower of missiles of every description from shells and rifle bullets down to bricks and stones. Upwards of 800 shells were aimed at the French Legation, of which the eastern side was literally pulverised. The defenders exercised the utmost caution, protecting themselves behind barricades and in trenches, but in spite of this they suffered severely. As might be expected most of the injuries were situated about the head or upper extremities. The following table, which was drawn up by Surgeon-Major Matignon with the help of Dr. Velde of the German Legation, gives some very interesting information.

Killed and Wounded at Peking, June—August, 1900.

Nationality.	Strength.		Killed.		Wounded.		Percentage.	
	Officers.	Men.	Officers.	Men.	Officers.	Men.	Killed.	Wounded.
German...	1	50	—	12	—	15	23·5	31·4
American	3	53	—	7	2	8	12·5	17·8
English...	3	79	1	2	2	8	3·7	24·4
Austrian	5	30	1	3	4	8	11·4	34·2
French	4	45	2	10	3	30	24·4	67·3
Italian	1	28	—	7	1	11	24·1	41·4
Japanese	3	24	—	5	1	21	18·5	81·4
Russian...	1	79	—	4	1	18	4·9	23·9
Volunteers	—	50	—	11	—	22	22·0	44·0

The technical part of the paper is full of interest and should be read *in extenso*. Some of the cases described are remarkable. In conclusion the author of the paper considers the following circumstance sufficiently curious to deserve mention. Out of 22 officers of all nationalities who took part in the defence there were 19 combatants and 3 medical non-combatants. In the first category 14 were wounded, the percentage being 73·6. The proportion is extremely high, but amongst the non-combatants it was higher still, equalling cent. per cent., inasmuch as each of the trio received a wound.

THE IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE St. Patrick's festival dinner of the Irish Medica Schools' and Graduates' Association was held on March 16th at the Hotel Cecil, Dr. William Alexander being in the chair. The interesting incident of the evening was the first presentation of the Arnott medal which has been founded by Mr. D. Arnott in memory of his father the late Sir John Arnott, whose name is well known in connexion with the promotion of Irish industries. The medal is to be given annually to an Irish graduate or diplomate in medicine who has specially distinguished himself in the field or in medical science. The first recipient of the medal, Captain Charles Dalton, R.A.M.C., was presented to the president of the association by Dr. T. Gilbart Smith, who stated that the honour was conferred in recognition of his gallantry and distinguished

services, particularly during the operations on the Tugela river, where on Jan. 23rd, 1900, he was dangerously wounded in the abdomen whilst attending a wounded officer under heavy fire; he was mentioned in despatches by Lord Roberts. The toast of "Our Defenders" was proposed by Dr. H. Macnaughton Jones, and was responded to by Inspector-General W. H. Lloyd, R.N., Captain Dalton, R.A.M.C., and Surgeon-Major W. Moyle O'Connor. Sir William Mac Cormac gave the toast of "Our Guests," which was replied to by Colonel Gallwey. The number of guests amounted to over 150, and the excellent singing between the speeches was much appreciated. Mr. P. J. Freyer and Dr. J. H. Swanton were heartily congratulated on the success of their efforts in organising the dinner.

MEMORIAL TO THE LATE PROFESSOR TOM JONES.

THE fund which is being raised by friends of the late Professor Tom Jones to establish a memorial to him in the Owens College has now reached nearly £850. We are sure that it will be gratifying to many who valued the late professor's character and work that such a satisfactory proof of the esteem in which he was held has been shown by the contributors of this considerable sum. We are asked to state that it is intended to close the fund on March 25th and that a meeting of subscribers will be called shortly afterwards. Subscriptions may be sent to the honorary treasurer, Mr. G. A. Wright, 16, St. John-street, Manchester, or to one of the honorary secretaries. Mr. J. E. Platt, 14, St. John-street, Manchester, and Dr. F. J. H. Coutts, Cromar, Plymouth-grove, Manchester.

TRAUMATIC HERPES ZOSTER.

HERPES zoster from injury of a nerve trunk is rare. It occurs especially after wounds such as are produced by a cutting instrument or a fractured bone, and after amputations it may appear on the stump. Herpes zoster from simple contusions or lesions of the terminal nerve filaments is still rarer. At the meeting of the Société Médicale des Hôpitaux of Paris on Feb. 22nd Professor E. Gaucher and M. Henry Bernard communicated an interesting paper on this subject. They first referred to some recorded cases. Herpes zoster has been observed on the right eyelids and cheek after a blow. In two cases the eruption has followed a fall during gymnastic exercises. In another case a woman missed her footing and this caused extreme flexion of the lumbar region. Lumbo-abdominal herpes appeared on the side towards which the body was flexed. We may add that herpes zoster after lumbar sprain has also been observed by Besnier and by Didier.[1] An example of herpes produced by lesions of a terminal nerve filament is a case in which, after tooth extraction, zona of the forehead, the eyelids, and the cheek appeared on the same side. In two cases zona followed the taking of a very hot bath. M. Gaucher and M. Bernard related the following three cases which were observed by themselves. A man, aged 46 years, received a blow on the left side of the nose and on the left cheek. Immediately he commenced to feel pain in the whole of the left side of the head, principally in the temporal region. 48 hours later he sought advice for an eruption which had appeared at the injured spot. On the left ala nasi and the adjacent part of the cheek there was diffuse erythema covered with little vesicles, of which some were whitish and others were surmounted with a brown crust. There were similar crusts in the left nostril. The left anterior pillar of the fauces was redder than was the right and it was dotted with little whitish vesicles. There was no fever. The headache, which was entirely localised on the left side, still persisted. There were no "painful points" of facial neuralgia nor was there any sensory trouble, except slight hyperæsthesia in the position of the eruption. Under rest and a simple protective dressing the vesicles rapidly dried up, but the headache persisted for several days. In the second case a child, aged three years, superficially wounded himself with a toy below the left lower eyelid. Two days later a group of herpetiform vesicles appeared on the chin on the same side. In the third case a man received a contusion of the left flank. On the same day a vesicular eruption in the form of a girdle, occupying the left lumbo-abdominal region and presenting all the characters of zona, supervened. It formed an oblique band extending from the spine to the median line in front and was accompanied by acute pain. The time of appearance of zona after an injury is very variable. Sometimes it appears almost immediately (in an hour in one case); sometimes after a long interval (three years in a case described by Charcot). In the latter circumstance probably zona the result of a general infection develops on a *locus minoris resistentiæ* created by the injury, or the zona is symptomatic of slow nerve degeneration. The localisation of the eruption in relation to the injury is of interest. In some cases the zona is localised exactly on the injured region, primarily at any rate; secondarily, vesicles may appear on adjacent parts innervated by branches from the same trunk as the injured ones. In other cases the injured region is unaffected and the eruption appears on an adjacent region in the same area of innervation: either a lesion of a nerve trunk is followed by zona in its area of distribution or a lesion of terminal branches is followed by zona in the area of distribution of other terminal branches.

HOSPITAL TREATMENT OF COLLIERY CASES.

AT a meeting of the general committee of the Coventry and Warwickshire Hospital on March 13th the house surgeon (Dr. F. H. Day) called the attention of the house committee to the following matter. On Feb. 26th a lad named Ward was admitted to the institution from Wyken Colliery with a crushed hand. Afterwards the colliery people sent to Dr. E. N. Nason of Nuneaton asking him to go to the hospital and to examine the patient's hand. He telephoned to Dr. Day, who explained the condition of the injury, whereupon Dr. Nason declined to attend and he informed the colliery managers that the patient would have all needed attention at the hospital. It was stated that Dr. D. Crowe, another medical man in the district, was also communicated with on the subject and that he went to the institution, the patient being told to refuse to have anything done to his hand till he had been seen by Dr. Crowe. Dr. Day complained to his committee that it would be impossible to carry on the work of the hospital under these conditions, but that if a consultation was necessary in any case the usual staff could be called in. A house surgeon could not be hampered by having to submit to other medical men coming in from various parts of the county. The house committee thereupon instructed the secretary to write to the manager of the Wyken Colliery informing him that all cases sent to the hospital were treated by the medical staff and that it was neither desirable nor just that they should be expected to meet in consultation medical men from other towns in no way connected with the hospital; also that the mere fact of a case being sent to the hospital was an assumption on the part of those who sent it that they were satisfied with the competence of the medical staff. In reply to this letter the colliery manager (Mr. Liddell) offered an apology for the course which had been taken and explained that the sole object was to get a report of the nature of the injuries of the patient, such report being necessary. He did not doubt

the efficiency of the hospital staff. With the reading of this letter from Mr. Liddell the matter dropped. We trust that this is not the usual way in which collieries deal with the medical treatment of their workers. It is perfectly monstrous to suppose that the medical officer of a hospital will submit to have his diagnosis called in question by any practitioner whom an outside authority may choose to send. If Mr. Liddell wished to have a report upon the condition of the pitman's hand his proper course would have been to write to the house surgeon of the hospital asking for a report and inclosing the usual fee to be paid either to the house surgeon or the hospital according to the rules of the institution. If he was not satisfied with the report of the house surgeon he would have been quite within his rights in asking for another opinion from one of the visiting staff. However, he seems to have seen the error of his ways, and we hope that such an incident will not occur again.

THE EFFECTS OF DUM-DUM BULLETS.

A STRIKING instance of the very severe effects of Dum-dum bullets when fired at only a short distance was afforded by the suicide recently of a private in the Scots Guards. The newspaper reports are not very full, but sufficient can be gathered to show the extraordinary results produced. The man placed the muzzle of the rifle in his mouth and pressed the trigger with his foot. Some of the effects must doubtlessly be attributed to the action of the gases liberated from the cordite, for they were set free in large volumes and had to escape either by the mouth or through the channel formed by the projectile. The bullet was a soft-nosed or Dum-dum, and it passed through the hard palate, the base and vault of the skull, then through a cloth cap, and struck the ceiling. It had spread out or "mushroomed" and had lost its nickel sheath. The man's head was enormously swollen, many of the bones being broken and nearly all of the sutures opened. This was due to what has been called the "explosive" action of these high-velocity bullets; the contents of the skull acting as a liquid, the effect of the increased pressure due to the entry of the bullet is transmitted equally in every direction. The only wound in the skin was a vertical one at the back of the head more than nine inches long with sharply-cut edges. Most of the brain substance and many pieces of the skull bones were driven through this wound and scattered about the room. The injuries were remarkably severe, much more so than those resulting from the firing of a Martini-Henry rifle in a similar position, for in the case of similar suicides with that rifle the bones were merely perforated.

TYPHOID FEVER IN THE CITY OF YORK.

ON Nov. 17th the Local Government Board wrote to the town clerk of York that they had observed that 10 deaths from fever were reported to the Registrar-General as occurring during the quarter ending Sept. 30th in the registration sub-district of Micklegate. The Board therefore requested the town council to instruct their medical officer to prepare a report upon the prevalence of fever in the borough. This report, drawn up by Dr. E. M. Smith, medical officer of health of York, now lies before us. The report states that during the year 1900 244 cases of typhoid fever were reported to Dr. Smith as occurring in the sanitary district of the city of York. Of these 38 patients died—14 in hospital and 24 at their own homes. The death-rate from typhoid fever for the year was therefore 15·5 per cent. of the cases notified. During the first half of the year there were 23 cases with four deaths; during the second half of the year there were 221 cases with 34 deaths. As regards age-distribution, in 19 cases with two deaths the patients were under five years of age; 89 cases occurred in persons between five and 15 years of age, of whom five died; 52 cases in persons between 15 and 25 years of age, of whom 11 died; and 82 in persons between 25 and 65 years of age, of whom 19 died. Of the total number of cases 17 of the patients apparently contracted the disease outside the city. The unusual prevalence of typhoid fever during the second half of the year is attributed by Dr. Smith to the very dry spring and the very hot periods of the summer, which fostered and developed the evils attaching to the increasing number of specifically infected midden privies. During the first half of the year 23 cases occurred in 21 houses, and of these 21 houses 11 were associated with the existence of foul privies, and 10 with water-closets of which seven had defective drains. During the second half of the year 221 cases occurred in 171 houses, 97 of which had midden privies and 74 had water-closets. In the former there occurred 124 cases of typhoid fever, 27 of which were secondary and five of which had contracted the disease outside York. The large majority of the midden privies were more or less foul or leaking. In the 74 water-closet houses there were 97 cases, but deducting those houses where no sanitary defect was observed, so that probably the patients contracted the disease elsewhere, and those cases which were known to have become infected elsewhere, there remain 57 water-closet houses to consider. Of these 27 had defects of drainage, 16 were decidedly dirty, and 10, although not having defective drainage, were associated with polluted soil. In 15 water-closet houses only could no clue be found to the probable or possible origin of the disease. Dr. Smith states that taking the whole of the cases into consideration he finds that the majority were associated with midden privies most of which were foul or leaking. The water-supply, the milk-supply, and the consumption of oysters and ice-cream are stated to have had no connexion with the outbreak. Dr. Smith's chief recommendation is the abolition of all midden privies and the substitution of water-closets or dry ash receptacles. The report is very interesting from the large proportion of cases occurring in persons under 15 years of age, there being 108 such, with seven deaths, a case-mortality of 6 4 per cent.

APHASIA WITH LETTER-BLINDNESS BUT WITHOUT WORD-BLINDNESS.

DR. GUY HINSDALE of Philadelphia has published in the *Journal of the American Medical Association* of March 2nd an interesting case of aphasia with letter-blindness but not word-blindness which possesses a somewhat exceptional value in that the patient was a physician belonging to a well-known institution. The patient was a man, 35 years of age, the subject of pulmonary phthisis, probably of about four years' duration. On Jan. 2nd, 1899, he had a sudden attack of paralysis involving the right face, arm, and leg, with almost total loss of speech. During the first 24 hours he could only speak the word "no." On the next day he could utter four words, could move his right arm, and had good control of the facial movements. He regained power steadily after this. On the ninth day he walked to the sitting-room and insisted on helping himself to tobacco and a glass of wine. On the eleventh day he was able to write his name for the first time and his vocabulary was steadily increasing. When shown a silver pencil he could not name it; when asked if it was a knife he said "No." "A pencil?" "No." "Something to write with?" "Yes." On the nineteenth day he was shown a silver dollar, but could not say what it was. "Is it a watch?" "No." "Is it a wheel?" "No." "Is it a piece of iron?" "No." "Is it a dollar?" "Yes, it is a dollar." He was given a few coins; he added them in a properly written column with the total value correct. He mispronounced some words and used

words incorrectly in a sentence. For example, he said "the quiet was," instead of the reason was; "glass of ice-water," for a pair of scissors; "spade," for paper; and "put those groups afay for me," for put those grapes away for me—paraphasia. He had letter-blindness but not word-blindness. When shown the alphabet he counted "One, two, three," instead of A, B, C. When shown the words "boy" and "child" he instantly pronounced them. He read the daily papers regularly and read McMaster's "History of the United States" and enjoyed it. Dr. Hinsdale points out that the letter-blindness is a most interesting and unusual feature. There may be word-blindness without letter-blindness, or *vice versâ*. If by disease affecting the brain the visual word-centre is completely destroyed, or if it is completely cut off from the primary visual perceptive centre in the occipital lobe, then the patient is both word-blind and letter-blind. But if the destruction is only partial and that part of the centre in which are stored the visual memories of letters remains intact, then the patient, though still able to recognise the individual letters by sight, will no longer be able to recognise and interpret words, because he has lost the visual memories for words which he had acquired by years of laborious effort. In the present case the clinical evidence points to hæmorrhage or embolism of the left Sylvian artery resulting in hemiplegia and aphasia. The visual word-centre is supplied by a branch of the Sylvian artery, and it is probable that an embolus lodged in this branch or in one of its twigs produced a partial softening and destruction of a part of this centre. The hemiplegia was recovered from, but the aphasia persisted at the end of nearly 18 months, to the annoyance of the man, whose living as a physician depended upon the free exercise of his highest intellectual functions. He shortly afterwards died from phthisis.

CARBONATED BOTTLED BEER.

MUCH of the bottled beer on the market is undoubtedly carbonated; that is to say, its sparkling quality depends not upon the gas generated in the beer itself by normal fermentation but upon artificial gas forced into the liquid in the same way as soda water is made. With a little experience it is not difficult to distinguish beer so charged artificially from beer charged with its own gas and developed in the liquid by fermentation. There are reasons why this artificial recourse should be discouraged, and, to start with, beer thus artificially charged with carbonic acid gas is, there is reason to think, dietetically inferior to beer charged with its own natural gas. Beer does not "assimilate" forced gas in the same way as when the gas is generated within the liquid, neither has carbonated beer the smoothness on the palate of normally sparkling beer and it soon becomes flat and stale. Indeed, it is probable that unsound and vapid beer may be passed off as a sound article by being forcibly charged with foreign carbonic acid gas and the practice is on this account objectionable. The sparkling quality of champagne is derived, of course, from the fermentation of the "liqueur" which is placed in it prior to the final corking in bottle. The gas is generated within the liquid and imparts to it a pleasant, attractive, and wholesome effervescent quality. On account of the gas being generated within the liquid it is retained in, so to speak, a nascent state and is therefore gradually disengaged on removal of the cork. The effervescence thus lasts for a considerable time. Champagne if it becomes flat cannot be made to resume its pleasant sparkling quality to the same degree by forcing gas into it. Yet another example occurs in the case of so-called "stone" ginger-beer which sparkles with carbonic acid gas generated by the fermentation of the liquid. For this reason it is probable that "stone" ginger-beer is generally preferred—as it is more palatable and wholesome—to ginger-beer prepared by carbonating a sugary infusion of ginger. The advantages of a natural mineral water, again, as opposed to the artificial mineral water are well known. The gas in a natural water is undoubtedly in some combined form which is not quite understood. At any rate, naturally impregnated waters are softer and smoother on the palate than artificially carbonated waters, while the former yield up their gas more slowly and in more minute bubbles than does the latter. Similar advantages are obtained in the case of beer which effervesces with the carbonic acid gas normally developed in the liquid by fermentation. For dietetic purposes such beer is much to be preferred to beer into which carbonic acid gas is artificially forced. By the way, it is not, we fancy, generally known that bottled beer was accidentally discovered by Alexander Nowell, head master of Westminster School, *circum* 1543; he was also the author of the Catechism. A curious collocation. Particulars of his life are to be found in the "Dictionary of National Biography" and in Mr. Sargeaunt's "Annals of Westminster School."

THE HOUSING QUESTION.

MR. GEORGE CADBURY, a member of the well-known firm of cocoa manufacturers, who, we believe, belongs to the Society of Friends, has just set a noble example by a gift in trust of property valued at nearly £180,000. The property consists of a portion, in extent 330 acres, of the Bournville estate. Of this 330 acres one-third has been laid out and upon it are built 370 cottages, of which 143 have been sold at cost price on leases of 999 years. Those who have paid less than half of the cost are charged 3 per cent. interest, while those who have paid more than half are charged 2½ per cent. The remaining cottages, shops, and the like are let to weekly tenants and the rents accruing from these are paid into the trust. There are also 200 allotment plots, and in addition gardening classes have been formed, to each member of which is allotted a small plot, the classes being under the care of the Worcestershire County Council. The total rent-roll is £5245 per annum and the remainder, after current expenses are paid, is to be administered by the trust for the development of the estate. It is intended to purchase similar estates with the profits from the present one, and of such one-fifteenth only may be used for manufactories and one-tenth at the least is to be kept as open spaces, while the remainder is to be laid out on the Bournville model with cottages and gardens, the buildings not to cover more than one-fourth of the land on which they are erected. The idea of the founder is that the race should be helped to maintain its physique by the workers in factories being given opportunity to spend their leisure in recreation out of doors. Mr. Cadbury's scheme approaches as nearly as is possible under the modern conditions of manufactories to the ideal state in which the master, his apprentices, and his workmen lived under one roof and had common interests. Probably, as in all experiments, there will be mistakes and failures at first, but the idea is a noble one, and if something similar could be carried out for London, to say nothing of other large manufacturing towns, the new century would be worthily inaugurated.

APPENDICITIS DUE TO INTESTINAL WORMS.

AT the meeting of the Paris Academy of Medicine which was held on March 12th M. Metchnikoff made a most interesting communication. As Deputy Director of the Pasteur Institute M. Metchnikoff had been struck by the number of cases of appendicitis, true or false, in which he had been able to assign intestinal worms as the exciting cause, more especially in children. He cited three particularly instructive cases which had been under the care of Dr. Lemoine. All these cases showed

signs of a grave appendicular crisis, and upon a microscopical examination of the fæces being made there were found the ova of various parasites, such as the ascaris and the ova of nematode or trichocephalous worms. Vermifuge treatment expelled the worms and the crisis ceased as if by magic. Further microscopical examination revealed the presence of more ova and the treatment was continued until the patients were entirely cured. One of them had suffered from recurrent attacks every two or three months for four years. These facts are not new, for Boeckel and Davaine have already reported cases of appendicitis which coincided with the presence of intestinal worms, while Natale has described an inguinal abscess of appendicular origin which burst outwardly and gave exit to 16 living ascarides. Several surgeons, among whom are M. Brun and M. Guinard, while removing appendices have found various parasites within them, while sometimes an ascaris has been found outside the appendix, having escaped through a perforation. M. Metchnikoff does not consider that the worm is able to perforate the appendix by itself, but it brings about an injury to the mucous membrane which is then attacked by microbes, and through the ulcer thus formed the worm forces its way. Therefore, says M. Metchnikoff, a certain number of cases of appendicitis are due to the above-mentioned causes and can be cured by the treatment indicated. The fæces should be always examined microscopically for the existence of ova, and just as the sputa are examined in diseases of the lung or the urine in diseases of the kidneys, so the fæces should be examined in diseases of the intestine. As a means of prophylaxis in these tricky (*tournoises*) forms of appendicitis care should be taken to avoid such articles of food as carry with them the ova of parasites, such, for instance, as raw salads or raw fruit which has not been washed.

THE ROYAL INFIRMARY OF NEWCASTLE.

WE have to offer our hearty congratulations to the inhabitants of Newcastle-on-Tyne and its neighbourhood, and particularly to the governors of the Royal Infirmary, on the good fortune by which they are now enabled to proceed freely and cheerfully with the erection of the building of which His Majesty the King (then Prince of Wales) laid the foundation-stone on June 20th, 1900. They have been splendidly supported, first, by the inhabitants of the town and district subscribing over £100,000 towards the Jubilee Fund in memory of Her late Majesty's incomparable reign; secondly, by the will of the late Mr. John Hall of Newcastle, who left £100,000 towards the object on conditions that we need not here specify; and, lastly and most recently, by the munificent gift of £100,000 from Mr. and Mrs. Watson Armstrong, who are nobly desirous of so commemorating their distinguished relative Lord Armstrong in the city of his birth and around which his affections centred. Some delay has been occasioned in the building operations by the terms of Mr. Hall's will, but all difficulties have now been removed by the judgment of the Chancery Division of the High Court of Justice and by the almost coincident event of Mr. and Mrs. Watson Armstrong's gift, which was announced to the public in a letter to Sir George Philipson read on March 14th to the committee of the infirmary. We have only to express the hope that the new building will be worthy of the generosity with which it is promoted and of the great district in which it must long be a conspicuous object. We cannot doubt that under the wise guidance of Sir George Philipson and his colleagues upon the board of management the funds will be carefully administered, with chief regard to the welfare of the sick and injured for whose benefit it is being raised. The importance of the Newcastle School of Medicine and the excellence of the medical and surgical work done even in the old infirmary are generally recognised and are not unduly rewarded by the munificent gifts which we now notice.

OBSTETRIC FEES AND MEDICAL CONTRACTS.

IN the colliery districts the miners are slow to realise the fact that they pay their medical men very poorly. Receiving much larger wages themselves than they used to do they might be expected to feel more acutely the inadequacy of the remuneration which they give for medical attendance. "A General Practitioner," whose letter appears on another page, complains that some of the large sick clubs are trying to reduce the obstetric fee from the recognised guinea to ten shillings. We agree with our correspondent that such terms will not survive a fair discussion by selected committees from each side.

THE freedom and livery of the Worshipful Company of Leathersellers of London have been conferred upon Sir William Mac Cormac, President of the Royal College of Surgeons of England. The presentation was made at the hall of the company on March 13th. Sir William Mac Cormac having signed the required declaration in the presence of the Master and Court was robed by the clerk and afterwards conducted to the reception-room. A banquet, to which several guests had been invited, followed, and at its conclusion the health of the new freeman was drunk and the Master presented to him a handsome casket containing the certificate of freedom upon which was inscribed the following resolution of the Court—viz., "That having regard to his distinguished career and the services rendered to his country in South Africa Sir William Mac Cormac, Bart., K.C.V.O., President of the Royal College of Surgeons, be presented with the Honorary Freedom and Livery of the Company."

ON March 20th His Majesty the King received upwards of forty addresses from various educational and other bodies. Among the deputations were those representing Edinburgh University, Trinity College Dublin, the Royal College of Physicians of London, the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the Royal Scottish Hospital, the Royal Medical and Chirurgical Society, and the Royal Institute of Public Health.

THE vacancy for the post of ophthalmic surgeon to St. Bartholomew's Hospital caused by the death of Mr. Bowater John Vernon has been filled by the election of Mr. Holmes Spicer. Mr. W. H. Jessop becomes senior ophthalmic surgeon in the room of Mr. Vernon, with the appointment of lecturer in ophthalmic medicine and surgery.

SUBSCRIPTIONS towards the expedition to the Pacific Islands for the investigation of the causation of malaria can, we are informed, be sent to the honorary secretaries of the Epidemiological Society at 11, Chandos-street, Cavendish-square, W., and from them further particulars of the project can be obtained.

A TELEGRAM has been received at the Colonial Office, dated March 19th, 1901, from Sir W. F. Hely-Hutchinson, Governor of Cape Colony, reporting for the week ending March 16th 81 plague cases admitted to hospital: deaths, 29; suspects, 17; and contacts, 402.

THE Privy Council by Order in Council have extended the operation of Part II. of the Medical Act of 1886 to Italy.

This is the first step, we presume, in the promotion of reciprocity of practice between Italy and the United Kingdom.

Sir William Broadbent, Bart., has been appointed a Knight Commander of the Royal Victorian Order and Dr. A. R. Manby a member of the fourth class of the same order.

HISTORY OF RENAL SURGERY.

BY DAVID NEWMAN, M.D., F.F.P.S. GLASG.,
SURGEON TO THE GLASGOW ROYAL INFIRMARY.

III.[1]

NEPHROTOMY (*continued*).

AT the beginning of last century (1803) Richter describes very well the appearances of suppurative disease of the kidney and also indicates the mode of operating, but he does not recommend any new lines of treatment. A valuable contribution to the pathology of the subject is that given by F. A. Walter (1800). But by far the most complete and classical book was that published by Rayer which appeared in 1839–1841; it marked a very decided and complete advance in the study of disease of the kidney, included not only all that was then known in respect to renal disease, but was in itself a most perfect exposition of the subject. Rayer explained clearly the surgical treatment; he considered the question of nephrotomy, and in his description he observed that calculi do not form in the substance of the kidney but in the pelvis and calices. As to removal of the kidney, he summed up the opinion of the time in the following sentence: "Ce serait folie de tenter chez l'homme atteint de calculs une telle opération." The proposal to incise a kidney for calculus where there is no swelling in the loin and the patient is otherwise in good ealth is not to be thought of. Rayer's opinions on this subject undoubtedly exercised for many years a strong influence against all operations upon the kidney.

Within the next 30 years two important transformations occurred, bringing with them a complete revolution in surgical practice. Operations which formerly had been looked upon as chimerical were now brought within the sphere of practical surgery. In Edinburgh Simpson had introduced the employment of chloroform as a general anæsthetic (1848), and in Glasgow Lister (1870) had worked out his theory of sepsis, introduced the antiseptic treatment of wounds, and began to preach his simple gospel of surgical cleanliness. In the first half of the last century the only operations which a surgeon could undertake were such as could be conducted with great rapidity; the best surgeon was he who had the strongest will and the quickest fingers. Elaborate operations followed step by step could not be attempted and minute dissections were impossible, consequently diseases of deep-seated organs, such as the kidney, were left severely alone. Simpson's energy in advocating the use of Liebig's discovery (1831) transformed all this. At first gradually the surgeon stretched out his hand, as the hand of a blind man, frequently to be advanced and again drawn back; the touch was tainted. Now, seeing clearly by the light of the truth taught by Lister, he has brought within his domain all organs. He can now do, even for diagnostic purposes only, operations unthought of when the last century was young.

In this country Mr. (now Sir Thomas) Smith in 1869 (three months prior to Simon's first nephrectomy) was the first to suggest seriously the operation of cutting down upon the kidney for the removal of a calculus, in a paper read before the Royal Medical and Chirurgical Society of London,[2] and at the end of his paper he suggests, what Mr. John Douglas attempted in Edinburgh 130 years earlier, "that before attempting the operation on the living, the possibility of removing renal calculi by nephrotomy should first be decided by operation on the body of one who has died with a stone in the kidney." Sir Thomas Smith carefully described a method of exposing the kidney by lumbar incision and recommended the operation for diagnostic purposes and for the removal of stone. The paper appeared at a very opportune moment and exercised a strong influence on the minds of surgeons. In the same year Annandale and Spencer Wells also wrote in favour of nephrotomy.

NEPHRECTOMY.

Although Sinibaldus (A.D. 1650) exhorted the French and Roman chirurgions "to make the experiment upon brutes that they might with greater dexterity and readiness perform it (nephrectomy) upon man," Zambeccarius (A.D. 1670) was the first to experiment upon animals, and along with Roonhuyzen (A.D. 1672) was enabled to demonstrate that one kidney could be removed without necessarily producing death; he was also the first to contemplate the operation of nephrectomy upon man. As already indicated his example was followed by Blancard, Blundell, and others. Rayer condemned the operation, and prior to the introduction of anæsthetics such a prolonged operation was practically impossible. The introduction of anæsthetics has permitted the development of surgery. In the olden days all operations required to be performed with great speed, so that one of the first considerations in an operation was rapidity. Nephrectomy from its very nature could not be performed otherwise than with deliberation and care, but now all reason for haste has been removed and the surgeon can slowly and confidently proceed with his work, knowing that he is not inflicting pain and that the main object is to have the operation well done and free from septic infection. Before the introduction of the methods of Lister the instruments and the hands of the surgeon often carried into the wound septic material and not infrequently the dressings which were applied made matters worse. Now all this is changed; the surgeon has learned to be clean in the highest sense of the term and everything around him is kept free from possible contamination; but besides these two great factors there have been other circumstances which have gradually led up to the development of renal surgery as we now know it. The immediately collateral branches of surgery were, about this time, undergoing great and rapid changes.

The progress of abdominal surgery has not been in an even line of advance during the last 150 or 200 years. One department has moved forward while another has stood still or has even gone back. There is little doubt that the surgery of the abdomen was better known from 200 to 150 years ago than it was at 60 years from the present time. A great amount of good work was lost and neglected. Roussetus (A.D. 1581) advised drainage by a cannula, so also did Heister in the middle of the eighteenth century, and he recommended washing out the abdomen with solutions. In many of the books of that time—for example, Dionis—minute and careful directions are to be found regarding the suturing of wounds of the abdominal wall and the treatment of the peritoneum.

In the last century probably no operation has had more influence in encouraging the advance of abdominal surgery than ovariotomy. At the beginning of the nineteenth century operations such as ovariotomy had been attempted only, but were condemned by the leaders in surgery, and it was not until 1842 that Charles Clay of Manchester placed ovariotomy on a sure foundation. In 1858 Spencer Wells in London, and in 1862 Thomas Keith in Edinburgh, began to practise ovariotomy, and in 1868 Peaslee developed the operation in America. The rapid increase in the number of ovariotomies lead to a few mistakes in diagnosis and as a consequence the kidney was removed from the living body by Peaslee, Esmarch, Speigelberg, and Walcott, in the belief that the disease was ovarian, with the exception of the case of the last mentioned surgeon which was thought to be one of cyst of the liver. Wells, after removing an ovarian cyst, found that in addition to the tumour he had taken away a healthy kidney. About this time Simon of Heidelberg, and Czerny, by their successful operations for relief or cure of disease of the kidney, gave an enormous impetus to systematic operative interference and established the claim of renal surgery beyond dispute. Simon's article must be regarded as the starting point in any discussion on the subject of renal surgery, and a consideration of the facts which induced him to resort to extirpation of the kidney for the relief of disease must always be of special interest to the surgeon. A distressing case of urinary fistula, resulting from ovariotomy, having

[1] Parts I. and II. were published in THE LANCET of March 2nd (p. 649) and 9th (p. 726), 1901, respectively.
[2] Transactions of the Royal Medical and Chirurgical Society of London, vol. li., p. 211.

come under his care, and all resources having failed to relieve the sufferings of the patient, the advisability of extirpating the kidney suggested itself. Before, however, such an operation could be resorted to it was necessary to ascertain whether or not it was consistent with life suddenly to withdraw the function of one kidney and to throw the entire labour upon the other organ. Pathological records afforded him many instances in which one kidney had been gradually rendered functionally useless by *slowly progressing disease*, and where compensatory hypertrophy had gradually become established without disturbance to the economy. No doubt he was aware of the experiments of Prévost and Dumas and of Claude Bernard, if not of the much earlier observations of Zambeccarius, Blancard, and Blundell. But he had to satisfy himself whether or not *sudden* withdrawal of one kidney would be tolerated and to prove it by experiment upon animals. For the purpose of clearing up this point he performed 15 nephrectomies upon dogs and found (1) that the greatest risk of death was from peritonitis; (2) that primary and secondary hæmorrhages were less to be feared than he had anticipated; (3) that pyæmia and embolism were not met with in a single case; (4) that the effect upon the elimination of the renal excreta was not such as to lead to symptoms of uræmia; (5) that no albuminuria or hypertrophy of the heart resulted from the operation; and (6) that the remaining healthy kidney within a short time increased in size and was soon competent to perform the double duty suddenly imposed upon it. These results encouraged Professor Simon to perform the first nephrectomy designed upon definite physiological principles.

Simon's experiments were undoubtedly a severe test of the ability of the remaining kidney, but it must be remembered that such operations upon healthy animals are not exactly equivalent to what we have to deal with in man, where the kidney to be removed is always diseased and the condition of its neighbour is not in every case able to be ascertained. On the other hand, in many instances in the human subject, the opposite kidney from the one to be removed has undergone compensatory hypertrophy and so improved its functional activity and capability. Besides the question of the elimination of the renal excreta after nephrectomy there were other facts which required to be demonstrated by the experiments. In ligature of the renal artery, close to its origin from the aorta, was the ligature to be depended upon to control the blood-pressure, and when it became absorbed was the thrombus liable to be disturbed? Might not thrombi in the renal veins become detached and give rise to embolisms elsewhere? Could the deep wound heal without contaminating the peritoneal cavity? These questions having been settled by experiment (in April, 1869) Simon cut down upon the kidney of Margaretha Kleb, aged 46 years, and removed it. He carried out the operation in the most careful way, and the brilliant result he obtained spurred men to higher achievements.

Simon had no imitators for nearly a year. In April, 1870, Parker[3] removed a kidney from a female patient, aged 12 years, who suffered from hydronephrosis, but the patient died from shock on the day following. In December of the same year in America Gilmore[4] performed a successful nephrectomy for painful moveable kidney in a woman, aged 39 years, who was five months pregnant and who recovered without any mishap. The year following Simon's second nephrectomy and von Bruns's first operation were performed, and in March, 1871, von Bruns[5] in a case of lumbar urinary fistula with calculous pyonephrosis excised the diseased kidney. The patient, a German officer, died in 10 hours from collapse, and at the post-mortem examination the remaining kidney was shown to be occupied by multiple abscesses. In August, 1871, Simon performed the first nephrectomy for renal calculus pure and simple. The patient, a woman, aged 30 years, a resident of Savannah, Georgia, in the United States, consulted Simon in Heidelberg, and had the affected kidney removed. Simon confesses that he undertook the operation with a great sense of responsibility and much anxiety. Up to this time all authorities had condemned nephrectomy for renal stone, and the writings of Rayer had still a strong influence with the profession against the operation. It had not been attempted upon the human subject. The patient made a good immediate recovery from the operation, but died on the thirty-first day from septic infection of the wound. All went well till the twenty-first day; then the patient was convalescent, but as the dressings were being changed in the presence of Simon he was induced to explore the wound with his finger without any precautions as to disinfection. In a few hours the patient had a rigor, the temperature rose, and general sepsis ensued involving septic peritonitis and pleurisy. In 1876 Simon died, without again performing a nephrectomy, but he had already laid the foundation of renal surgery, and when the influence of Lister's teaching became generally felt and appreciated this department of surgery made rapid strides. During the first 10 years—that is to say, from 1870 to 1879—57 renal operations were performed with a mortality of 29, or a little over 50 per cent.

TABLE I.—*Renal Operations from 1870 to 1879.*

—	Nephrotomies.	Deaths.	Nephrolithotomies.	Deaths.	Nephrectomies.	Deaths.
For hydronephrosis and cystic disease	3	—	—	—	7	5
For septic disease without calculus	11	4	—	—	2	1
For septic disease with calculus	—	—	11	6	6	4
For tuberculosis	4	1	—	—	1	1
For tumours	—	—	—	—	12	7
—	18	5	11	6	28	18

During the next five years, from 1880 to 1884, 219 operations were performed, two-thirds of which were nephrectomies. Indeed, at this period nephrectomy was resorted to very freely and was adopted as the only remedy for conditions which are now treated by less heroic measures. The mortality all over was 71, or a little under 24 per cent.—a decrease of 50 per cent. on the mortality of the previous 10 years.

TABLE II.—*Renal Operations from 1880 to 1884.*

—	Nephrotomies.	Deaths.	Nephrolithotomies.	Deaths.	Nephrectomies.	Deaths.
For hydronephrosis and cystic disease	9	—	—	—	21	7
For septic disease without calculus	23	5	—	—	25	10
For septic disease with calculus	—	—	19	5	35	12
For calculus	—	—	17	—	—	—
For tuberculosis	8	2	—	—	23	9
For tumours	—	—	—	—	39	21
—	40	7	36	5	143	59

These statistics serve as a basis to illustrate the progress of renal surgery during the first 15 years of its growth. It will be very interesting to know the advancement that has taken place in the 15 years terminating with the end of the century. The writer has already endeavoured to collect the statistics of cases published up to the end of 1900.

In May, 1872, two nephrectomies were performed, one published by Peters[6] and the other by Durham.[7] The former case was the first nephrectomy for a tuberculous nephritis. The vesiculæ seminales and ureters were also involved, and the patient died from hæmorrhage in 65 hours. Andrew and Callender[8] have recorded a case of a lumbar nephro-lithotomy in a patient suffering from calculous pyelitis, and Dawson[9] gives an account of a similar case in which he performed an abdominal nephro-lithotomy with a fatal result.

These statistics are far from encouraging, but in the following year (1873) four successful cases were brought

forward—three nephrectomies and one nephro-lithotomy. In March, 1873, Marvand [10] performed a lumbar nephrectomy for prolapse of the right kidney through a lumbar wound. The patient had a rapid recovery and left the hospital 21 days after the operation. Three months later Brandt [11] performed the same operation in a similar case with an equally good result. In October W. Ingalls [12] of Boston performed a lumbar nephro-lithotomy in a case of calculous pyelitis with a good result, and in December Campbell [13] of Dundee successfully excised a cystic kidney by abdominal nephrectomy.

Of the next five nephrectomies, all performed for malignant disease, three of the patients died and two recovered. G. Kocher [14] of Bern operated on two cases of sarcoma of the kidney by abdominal nephrectomy, both of which were fatal; Langenbuch [15] performed a successful lumbar nephrectomy for sarcoma; and Mr. T. R. Jessop [16] of Leeds successfully excised through a lumbar incision the first kidney removed in this country for malignant disease. G. Hueter [17] also removed a sarcomatous kidney, but the patient died from hæmorrhage during the operation. The new ideas which had advanced in Germany, Great Britain, and America did not receive ready acceptance in France and Italy. It was not until 1880 that M. Léon Le Fort [18] performed nephrectomy for the first time in France, in a case of lumbar urinary fistula the result of a wound which divided the ureter. The patient died from shock 24 hours after the operation.

The great bulk of the early operations were nephrectomies; naturally the operation was resorted to only in extreme cases, and consequently the mortality was very high. At the end of 1879, excluding cases of erroneous diagnosis, 28 nephrectomies had been recorded—seven for hydronephrosis or cystic disease, with five deaths; two for pyonephrosis without calculus, with one death; six for calculous pyonephrosis, with four deaths; one fatal case for tuberculous disease; and 12 operations for malignant disease, with seven deaths. 18 nephrotomies were performed with five deaths, and 11 nephro-lithotomies for calculous pyonephrosis with six deaths.

Whether a kidney containing a calculus should be excised or not must depend upon the conditions in the individual case. It may be admitted that in cases where the organ has been destroyed by septic disease, and a considerable pyonephrosis has resulted, nothing short of excision will cure the patient; but when a stone is known to be present at a time prior to pyogenic infection the organ may be exposed and the calculus removed—to perform nephrectomy in such a case is not now justifiable. But up to 1880 no attempt had been made to remove a stone from an otherwise healthy kidney, with the exception of the cases recorded above, and these cannot be placed alongside the operation carefully contrived and carried out by Mr. Henry Morris of London in February of that year. He was induced to undertake the operation by the extreme severity and persistency of the symptoms in the case under his care, and he demonstrated for the first time that a calculus could be removed by cutting freely into the healthy renal parenchyma. This was a very distinct advance; it enabled the stone to be removed at an early stage in the disease before sepsis set in and the kidney was destroyed. The surgeon, instead of being contented by relieving the patient of a renal stone which has given rise to an abscess in the kidney or found its way to the surface by suppuration, anticipates nature and removes the calculus before it has produced destructive changes in the renal tissue. In this way not only is the kidney saved and the patient relieved, but by operating early in the course of the malady the immediate dangers formerly associated with the operation are reduced to a minimum.

Le Dentu [19] performed nephrolithotomy in France in October of the same year, and in Britain in the year following Mr. Marcus Beck [20] and Mr. H. T. Butlin [21] successfully removed calculi from an otherwise healthy kidney, and Dr. John Duncan [22] explored a kidney but failed to find the stone. A. E. Barker, Howe, Symonds, Anderson, K. Thornton, and others in this country took up the operation actively and in a few years the old fear of incising the renal parenchyma disappeared for ever.

THE ROYAL COMMISSION ON SOUTH AFRICAN HOSPITALS.

(Continued from p. 810.)

V.

IN a report in which continuity of arrangement has to be maintained it is unavoidable to have some overlapping, and there are consequently occasional references from one to other parts of the report of the Royal Commission on South African Hospitals which make it somewhat difficult of analysis. But a perusal of the summary which we have already published—with which we may assume our readers to be acquainted and to which they can refer—will make it easy for them to follow us in our comments.

We may take the following facts as an evidence of our unpreparedness for a campaign such as that which has actually occurred in South Africa. At the outbreak of the war there were only available staff and equipment for two army corps, and even the two army corps which were first employed in the war could only be staffed and equipped with difficulty. For the sixth division, according to the evidence of Major Bedford, R.A.M.C., the reservists had to be used and a mixed *personnel* employed. After providing for the first two army corps there existed only a reserve equipment sufficient to furnish one general and two stationary hospitals (page 8). It is easy to be wise after the event, but as a matter of fact no one foresaw at the beginning of the war that a force enormously larger than two army corps, in addition to the British troops already in South Africa, would be required. In other ways, too, the army corps unit allowance of field hospitals was reduced from nine or ten to six, and these hospitals in South Africa were ten short of the proper number, which shortage was never made up and caused a strain throughout the campaign. As regards the small reserve of hospital equipment, while seeing some force in the objection to keeping up permanently a large stock owing to the fear of much of it becoming obsolete, we concur with the Commission in thinking that this explanation is not wholly satisfactory. The total number of troops landed between September, 1899, and July, 1900, did not fall short of the aggregate of 230,000 men. At the time of the greatest pressure, which occurred at the end of the month of March, 1900, the total force then engaged being 207,000 men, there were in the country some 800 medical officers (including civil surgeons), 6000 hospital subordinates, and 800 nurses (page 10). When the enormous extent of country and the rapid and unexpected movements of the troops are taken into consideration, together with the extreme difficulties of transport and the necessity that such transport as was available should be used mainly with the view of meeting the necessities of the fighting force rather than for rendering medical aid, it must be admitted that the task imposed upon the medical service was herculean. Also the amount of medical aid available in the country generally was not distributed, it must be remembered, according to the needs of particular localities. These difficulties, which had to be more or less encountered generally, became most conspicuous at Bloemfontein during the months of April and May. Notwithstanding that the services of civil surgeons in the United Kingdom were available and largely utilised it took time to get them out to South Africa and the supply of local practitioners at the Cape was very limited. In opening out fresh hospitals and utilising these surgeons it was found essential to have a certain number of medical officers of the army employed for reasons which are uncommonly well put by Mr. Bowlby, senior surgeon in charge of the Portland Hospital, and set forth at page 9 of the report. The difficulty of supplying properly trained hospital orderlies was much greater than that of finding civil surgeons and, in fact, was never really overcome.

[22] Newman: Lectures on the Surgery of the Kidney, p. 258.

As regards the officers of the Royal Army Medical Corps, they could not be supplied, for the simple reason that they were not to be had in anything like sufficient numbers. It is notorious that the Army Medical Service has for years past been an unpopular one with the medical schools and hospitals. Some ascribe the cause to one thing—such as the abolition of the regimental system—some to another, or to a multiplicity of causes; but the fact remains that the service fails to draw the number of candidates required for its needs even in times of peace, to say nothing of war; and, what is more, even if it did draw them in abundance it would be impossible for financial reasons alone to maintain a permanent medical establishment of sufficient strength to meet the requirements of any big modern war. Recourse must, perforce, be had, and very largely had, to other expedients. The strength of the Royal Army Medical Corps must in any case be largely increased in the near future. But what should now be considered is the framing of some far more widely based and comprehensive scheme, which shall include not only the regular medical service as an integral part of the army, but the medical services of the militia, volunteers, and colonial forces, supplemented by as much medical aid as is needful in time of war from the staff of our civil hospitals and the medical profession generally. What seems to be wanted under the new and altered conditions of the British Empire is a scheme of organisation which would result in the practical formation of an Imperial Medical Service. Can such a scheme of medical aid be devised and organised on lines which will commend themselves to the understanding, patriotic sympathy, and favourable consideration of the whole medical profession at home and abroad? It surely should not pass the wit of man to devise something of the kind and we believe that to some extent the lines upon which it can be done have been indicated by the system adopted in Germany.

With regard to the complaints concerning medical officers of the Royal Army Medical Corps the report deals with the matter fairly and discriminately. As a whole their conduct and capacity are stated to deserve great praise. The number of those who have died during the war is unfortunately large. With the exception of a few instances the charges levelled against them were unfounded. The Commissioners in this connexion allude to the unattractiveness and under manning of the corps and the insufficient opportunities for leave and study in order to keep abreast with recent advances in the practice of medicine and surgery and other matters. The Commissioners recommend that immediate steps should be taken at the end of the war to increase the permanent staff of the Royal Army Medical Corps, and to provide for its speedy enlargement in times of great wars. Inducements must be offered to insure the continuous supply of sufficient men of good professional attainment, and means must be adopted for keeping them *au courant* with the results of medical progress so as to secure a high standard of professional efficiency (page 12). The Commissioners, in dealing with complaints that officers of the Royal Army Medical Corps are too military in their habits and conduct, contrast the great differences which exist between the nature and variety of the duties in civil and army life and refer to the excellent evidence of Mr. Bowlby and of Colonel Macnamara. Admitting to the full this distinction and the necessity for military rank on the part of officers of the Royal Army Medical Corps, they nevertheless think that there has been a tendency on the part of some of the officers, and still more on the part of the non-commissioned officers and men of the corps, to treat hospitals as if they were barracks and the occupants too much as soldiers and too little as patients (page 12). The report dwells upon the immense amount of work that had to be discharged by the principal medical officer and the head quarter medical staff in South Africa and the difficulties which they had to encounter—far greater than those to be met with in any ordinary campaign.

In South Africa the territory occupied by the troops is vast. In this territory numerous armies or bodies of men have been continuously and rapidly changing their positions. Often the army movements have been extremely sudden and no notice of them could be given beforehand to the medical staff. The medical arrangements for all these armies and troops had to be considered and provided for. In addition the medical staff had to consider and provide for the placing and shifting of the various hospitals on the lines of communication and the establishment of the hospitals at the base and the supply and care and transport of all the numerous requisites for sick and wounded men throughout the country occupied by our soldiers.

Of course, judging from events, we know that mistakes have been made by the staff in the course of this war and that things have not been foreseen which might have been. We have pointed out in dealing with complaints in Part III. instances of such mistakes and oversights. But taking their work as a whole and considering the difficulties they have had to contend with we think that the principal medical officer and his head staff have done excellent work. They have never spared themselves and have shown a great devotion to their duty and every desire to make due provision for the care of the sick and wounded, and when their conduct is fairly judged we think that they deserve great praise. The organisation of the field and stationary and base hospitals for the colonial troops, the militia, and volunteers fell upon the medical staff in South Africa, and in our judgment they met the difficulties presented to them with singular ability and success (page 13).

We may pass over much of the remainder of Part II. of the report, simply contenting ourselves with a few comments as we proceed until we come to the subject of sanitation. The report states that the civil surgeons employed during the campaign have, as a body, done their duty extremely well and, as a rule, worked well with the Royal Army Medical Corps. As a whole the orderlies discharged their duties satisfactorily, notwithstanding that there have been numerous complaints against them, some of which were apparently well founded. Many of the orderlies showed great devotion. Whilst upon this subject we may say that a better class of men, physically and socially, is required. Orderlies are insufficiently paid, and their training should be improved in a medical and not in a military direction. They are often not physically strong enough for their duties and it must be borne in mind, a fact which seems to have been forgotten, that in lowering the physical standard for the men of the corps another and less desirable stratum of the population is tapped. It is not so much military smartness as respectability, hospital training, intelligence, personal cleanliness, and skill in the execution of their ward duties as sick-attendants that are required from the men of this corps.

Of the private hospitals there is little or nothing said in the report that is not favourable. The differences and points of contrast between civil and military hospitals are pointed out. The numerous private hospitals were, it need scarcely be said, a very material aid in this war, and the army medical service is entirely in accord with the nation in their high appreciation of the work these hospitals did. Some of them were fitted out with an elaboration of detail, convenience, and comfort that left little or nothing to be desired It is unreasonable to anticipate, however, that the Government can compete and vie with private enterprise and philanthropic effort in this respect, and we consider that so long as war is war it is vain to expect military hospitals to be furnished on a splendid scale like that of the Yeomanry hospital, for example. Nor is it necessary or desirable. We are not in accord with Mr. Murray Guthrie, M.P. (*vide* Nos. 2307, 2308, 2482, and 2483, Minutes of Evidence). His evidence seems to us misleading in character. With reference to the remarks of Mr. Burdett-Coutts, M.P., and Mr. Murray Guthrie, M.P., about the death-rate being less in civil than in military hospitals, at page 15 of the report an attempt is made on a limited scale to institute a comparison between the death-rates of private hospitals and military hospitals. A return is furnished by Surgeon-General W. D. Wilson of the percentage ratios of deaths from general causes and from enteric fever in five hospitals—two military and three civil. The result of the comparison is, on the whole, favourable to the military hospitals, but such comparisons are, for various reasons, often untrustworthy and misleading. Touching charitable gifts the Commissioners make the practical suggestion that in future wars it would be advisable to have them all received and dealt with by one organised body. There will never be any absence of supplies of comforts of all kinds for our soldiers in time of war. They will be forthcoming in embarrassing abundance when the national feelings of patriotism and philanthropy are once roused, but great difficulty will attend their distribution. We require, indeed, to have our whole charitable system and organisation in time of war inquired into with a view to see whether its machinery can not be remodelled and placed on a simpler, more effective, and economical basis. Special praise is given to the ambulance trains so largely used in the campaign. The Commissioners speak highly of the state in which they found the hospitals in South Africa at the time of their visit and express an opinion that the institutions were quite able to cope with an outbreak of enteric fever or other disease should it occur (page 16). This condition will be attributed by some to Mr. Burdett-Coutts's strictures, and by others simply to the fact that the temporary state of extreme strain and pressure which undoubtedly existed when he saw them had passed away. No doubt both factors may have exercised an influence, but, in our opinion, the latter was the main one.

We are very glad to notice that the report decisively affirms that the head of a military hospital should be a member of the Royal Army Medical Corps, and we fully concur in what the Commissioners have to say on the subject and with the tenour of the evidence of military officers generally thereon.

With regard to what is vaguely known, but nevertheless pretty well understood, by the term "red tape," comprehending returns, records, difficulties, and delays in respect of the requisitioning of necessaries, &c. (p. 17), the report contains much that is very pertinent and sensible. The House of Commons must, we fear, be held to be responsible (directly and indirectly) for a good deal of laborious clerical work so long as it is open to Members to call for returns on every conceivable subject. That a certain number of official records and returns of various kinds must, under any system, be maintained is unquestionable, but the amount of clerical labour in the service generally is one of the worries of army life, and, we think, of army medical life in particular, whether in peace or war. It diverts too much of the medical officer's time and attention from far more important duties and makes him too much dependent on his soldier clerks. The subject requires to be very carefully gone into with the view of seeing whether clerical labour could not be materially reduced and simplified. To take one example by way of illustration, the medical record of cases should be governed by their severity or interest and not by the mere fact that something extra in the way of diet had been ordered. It certainly looks as if the design were not at all in the interest of the patient, but to restrain the hand of the prescribing officer by giving him extra and unnecessary trouble.

As regards the delay and difficulties which arise from medical officers having to get their supplies from the Army Service Corps the Commissioners make a highly important suggestion, and it is this :—

> Whether this can to any and what extent be avoided with practical advantage by permitting the Royal Army Medical Corps to have sole possession of, and control over, all hospital necessaries (other than ordinary food and ordinary clothing), including such things as beds, mattresses, and hospital clothing, is a question which should be considered by the committee which we have already mentioned.

There are many medical officers of experience who regard this as the root of the whole matter and consider that until the army medical service is self-contained and complete in itself in every respect, so as to render it independent of supply departments, there will and must be recurring failures. This subject, together with that of transport, is regarded by them as one of primary importance, but the consideration of it will more fitly and conveniently arise when we come to consider that part of the report devoted to "suggestions with a view to remedying defects."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on March 14th, Sir WILLIAM MACCORMAC, Bart., K.C.V.O., the President, being in the chair.

The SECRETARY reported the death, on Feb. 2nd (Jan. 20th O.S.), of Professor Victor Pachoutine, Hon. F.R.C.S. Eng., President of the Imperial Military Academy of Medicine at St. Petersburg; and the PRESIDENT stated that he had written to Madame Pachoutine and to the Imperial Military Academy of Medicine to express the sympathy and condolence of the Council.

The PRESIDENT nominated Dr. S. Monckton Copeman and Dr. Christopher Childs for appointment by the Council as the delegates of the College to the Congress of the Royal Institute of Public Health to be held at Eastbourne in July next.

The PRESIDENT reported that, in pursuance of the provisions of the Bradshaw Bequest, he had chosen Mr. T. R Jessop as Bradshaw Lecturer for the ensuing collegiate year.

The PRESIDENT reported the delivery of the Hunterian Oration by Mr. N. C. Macnamara, and the best thanks of the Council were given to Mr. Macnamara for his oration and he was requested to publish it.

The PRESIDENT and VICE-PRESIDENTS reported that, subject to the approval of the Charity Commissioners, they had accepted a design from Mr. Allan Wyon for dies for the Cartwright medal.

A report from the Board of Examiners in Dental Surgery was read; it was referred to a committee of the Council to consider. The report contained suggestions for alterations in the curriculum and in the examinations. Memorials were received from the staff of the Victoria Dental Hospital of Manchester and from the staff of the Liverpool Dental Hospital referring to the proposed changes.

A letter was read from Mr. George Brown and Dr. G. Danford Thomas specifying the points in regard to which they are of opinion that the Medical Acts require amendment. This was in answer to a letter from the Council in reference to a resolution carried at the annual meeting of Fellows and Members.

The following resolution was carried unanimously, and an illuminated album containing it, with the signatures of the Council, was presented to Mr. Edward Trimmer, M.A., the secretary, who is retiring after 42 years' service:—

> On the occasion of the retirement of Mr. Edward Trimmer from the office of secretary to the Royal College of Surgeons of England the Council gladly avail themselves of the opportunity to express to him their very high appreciation of his services to the College and their warm regard for him personally.
>
> The powers of organisation displayed by Mr. Trimmer during the time the arrangements for the examinations were under his supervision, his experience in all matters relating to procedure, his thorough mastery of the charters and by-laws, and his exceptional knowledge of the history of the College, have enabled him to render to the College services of the greatest value, and the Council cannot but feel that they are losing an officer who has always maintained the high traditions of the College and successfully striven to advance its interests.
>
> His unfailing courtesy, genial manner, and sound judgment have justly caused him to be highly respected, and whilst the Council express the hope that in his retirement Mr. Trimmer will enjoy many years of health and happiness, they assure him that neither he nor his services to the College will be forgotten by those who have had the pleasure of associating with him.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Kettering Urban District.—Mr. J. Winter Dryland expresses the opinion that in so far as this district is concerned the time is not yet ripe even for the voluntary notification of phthisis; but he reports that a veterinary inspector has been appointed to inspect the cows supplying milk to the town. After deaths from phthisis the invaded house is carefully disinfected and handbills are distributed drawing attention to the manner in which the disease is spread.

Borough of Kensington.—Dr. T. Orme Dudfield's last monthly report contains a summary of the vital statistics for 1900. The estimated population of the borough at the middle of the year in question was 173,000. The birth-rate was 20·7 per 1000 (as contrasted with a rate of 33·1 in 1868) and the general death-rate was 15·6 per 1000. The infantile mortality was 179 per 1000 births, as compared with 159 per 1000 births for London as a whole. This high rate was in large part due to an excessive infantile mortality, 290 per 1000 births, in the north-west district.

Maldon Rural District.—The southern part of this district has been fortunate in being provided during 1900 with an adequate supply of pure water drawn from springs thrown out from the gravel by the underlying London clay. The greater part of this district seems now, thanks to the energetic action of Dr. Thresh, to be well supplied with water. The Maldon Rural District Council during 1900 applied to the county council for sanction to adopt Part III. of the Housing of the Working Classes Act, 1890. The application was granted, but the committee of the county council which conducted the inquiry point out that most of the cottages attached to the farms are let at a much too low rental, the labourers accepting this substitute for a low weekly wage. It was urged by some of the witnesses that 1*s* 6*d*. a week was all that could be paid by the labourers, but the county councillors observe in their report that no decent cottages can be built for a rental such as this. If the actual value of the cottage was charged to the labourers there might be some inducement to private enterprise, but as it is there is none. Nevertheless, the county councillors granted the application.

Whitechapel Sanitary District.—The formation of the Metropolitan Borough of Stepney has put an end to the district of Whitechapel as a separate sanitary unit, and Mr. Joseph Loane, the medical officer of health, finds himself among those officers whose posts are abolished from March 25th next. In this, his last report, Mr. Loane furnishes a short retrospect of the work done in Whitechapel and of the development of the sanitary staff since he took office 18 years ago. Overcrowding has, Mr. Loane tells us, been the worst problem which he has had to face, and in his opinion the attempt to remove the workers to the suburbs will never succeed unless and until they are able to take their workshops and their factories with them. He thinks that efforts should be made to undersell the "house-sweaters" by erecting good healthy dwellings for the people at rents not exceeding 3*s.* per room per week, and in his view the aid of wealthy philanthropists must be called in. But what will the political economists say to this?

Kingston-on-Thames Urban District.—The Thames Conservancy has apparently expressed its dissatisfaction with the effluent turned out from the Kingston sewage works and the corporation is concerning itself with the problem of procuring a more satisfactory effluent. With this object in view the medical officer of health, Mr. H. Beale Collins, has visited many experimental works and has reported thereon to the corporation. As regards the control of tuberculosis the medical officer of health advises that the example of neighbouring authorities should be followed and that all cows in the Kingston district should be tested with tuberculin by a veterinary inspector. Much milk comes into Kingston from outside districts, and Mr. Collins protests against the careless method of transport of such milk and he draws attention to the unprotected manner in which the milk churns are sent by train. Certainly anyone who travels much by train has ample opportunities of seeing illustrations of this carelessness. The Kingston Corporation is enjoined by its medical officer of health to take a lesson from the successful Danes in the matter of dairy produce.

Carlisle Urban District.—Mr. William Brown, the medical officer of health of this city, reports that the public slaughter-houses have been a great success. Before their erection slaughtering was carried on in 27 private slaughter-houses under very unsatisfactory conditions. In the five years preceding the erection of the public slaughter-houses only one case of tuberculosis came to the notice of the sanitary authority. For the last five years an average of 53 tuberculous carcasses have been examined. The veterinary inspection of dairy cattle was carried on during 1900, and the diseases discovered were tuberculosis, acute inflammation of the udder, congestion of the lungs, hæmaturia, and cow-pox. Tuberculosis in the human subject is compulsorily notifiable in Carlisle, and notification during 1900 brought to light 18 cases of phthisis and three of tabes mesenterica, but Mr. Brown does not tell us what action was taken as a result of such information.

Worcester County District.—In preparation for the "Consumption Conference" which was held at Worcester on Feb 9th, Mr. G. H. Fosbroke, the county medical officer of health, prepared a useful map and some charts, illustrative of the behaviour of phthisis in the county. The charts show a steady fall since 1861, and it is gratifying to learn that Worcestershire, as compared with other counties, has a very low death-rate from phthisis, in fact, it shares the honour of least phthisis mortality with Staffordshire and Leicestershire.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6822 births and 4280 deaths were registered during the week ending March 16th. The annual rate of mortality in these towns, which had been 21·5 and 19·6 per 1000 in the two preceding weeks, further declined to 18·9 last week. In London the death-rate was 17·6 per 1000, while it averaged 19·8 in the 32 large provincial towns. The lowest death-rates in these towns were 13·8 in West Ham, 14·3 in Burnley, 14·6 in Brighton and in Swansea, 14·7 in Bolton and in Derby; the highest rates were 24·8 in Oldham, 26·6 in Plymouth, 28·2 in Liverpool, and 29·0 in Sunderland. The 4280 deaths in these towns included 370 which were referred to the principal zymotic diseases, against 395 and 376 in the two preceding weeks; of these 112 resulted from whooping-cough, 105 from measles, 66 from diphtheria, 30 from scarlet fever, 29 from diarrhœal diseases, and 28 from "fever" (principally enteric). No death from any of these diseases occurred either in Brighton or in Swansea; in the other towns they caused the lowest death-rates in Portsmouth, Plymouth, Norwich, Huddersfield, and Bradford; and the highest rates in Bristol, Derby, Liverpool, Salford, and Sunderland. The greatest proportional mortality from measles occurred in Liverpool, Leeds, and Sunderland, and from whooping-cough in Bristol, Cardiff, Derby, Birkenhead, Halifax, and Sunderland. The mortality from scarlet fever and from "fever" showed no marked excess in any of the towns. The 66 deaths from diphtheria included 30 in London, six in Sheffield, four in Leeds, four in Salford, four in Liverpool, and four in Bristol. No fatal case of small-pox was registered last week in any of the 33 towns, and only one small-pox patient remained under treatment on Saturday last, March 16th, in the Metropolitan Asylums hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1652, against numbers decreasing from 2535 to 1746 on the 11 preceding Saturdays; 130 new cases were admitted during the week, against 162, 185, and 140 in the three preceding weeks. Influenza was certified as the primary cause of 30 deaths in London last week, as compared with 32, 35, and 39 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 501 and 463 in the two preceding weeks, further declined last week to 394, and were 124 below the corrected average. The causes of 63, or 1·5 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Manchester, Bradford, Leeds, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Sheffield, Hull, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·5 and 23·4 per 1000 in the two preceding weeks, further declined to 22·7 per 1000 during the week ending March 16th, but was 3·8 per 1000 in excess of the mean rate during the same period in the 33 large English towns. Among these Scotch towns the death-rates ranged from 11·1 in Leith, and 13·4 in Perth, to 24·4 in Glasgow and 25·4 in Edinburgh. The 713 deaths in these towns included 40 which were referred to whooping-cough, 24 to small-pox, 10 to measles, seven to diphtheria, six to "fever," six to diarrhœa, and five to scarlet fever. In all, 98 deaths resulted from these principal zymotic diseases last week, against 122 and 113 in the two preceding weeks. These 98 deaths were equal to an annual rate of 3·1 per 1000, which was 1·5 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 67 and 51 in the two preceding weeks, further declined last week to 40, of which 22 occurred in Glasgow, seven in Edinburgh, five in Dundee, and four in Greenock. The deaths from small-pox, which had been 15, 12, and 20 in the three preceding weeks, further rose last week to 24, and were all registered in Glasgow. The fatal cases of measles, which had been 13 and 15 in the two preceding weeks, declined again to 10 last week, and included five in Edinburgh, two in Glasgow, and two in Aberdeen. The deaths from diphtheria, which had been two in each of the two preceding weeks, rose last week to seven, of which six occurred in Edinburgh. The six fatal cases of "fever" corresponded with the number in the preceding week, and included three in Glasgow. The deaths from diarrhœa, which had been 23 and 15 in the two preceding weeks, further declined last week to six, of which three occurred in Glasgow, where four of the five fatal cases of scarlet fever were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 184 and 161 in the two preceding weeks, rose again last week to 171, but were slightly below the number in the corresponding period of last year. The causes of 26, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 46·6 and 39·6 per 1000 in the two preceding weeks, further declined to 34·6

per 1000 during the week ending March 16th. During the past four weeks the death-rate in the city has averaged 38·6 per 1000, the rate during the same period being 19·7 in London and 23·4 in Edinburgh. The 230 deaths belonging to Dublin registered during the week under notice were 33 below the number in the preceding week and included 14 which were referred to the principal zymotic diseases, against 12 in each of the two preceding weeks; of these, 11 resulted from whooping-cough, two from diphtheria, and one from "fever." These 14 deaths were equal to an annual rate of 2·1 per 1000, the zymotic death-rate during the same period being 1·6 in London and 3·4 in Edinburgh. The fatal cases of whooping-cough, which had been three, five, and 10 in the three preceding weeks, further rose last week to 11. The mortality from diphtheria showed a slight increase over that in recent weeks. The 230 deaths in Dublin last week included 41 of children under one year of age and 72 of persons aged upwards of 60 years; the deaths of infants exceeded the number recorded in the preceding week, while those of elderly persons showed a decline. Four inquest cases and five deaths from violence were registered; and 73, or nearly one-third, of the deaths occurred in public institutions. The causes of 16, or nearly 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Inspector-General of Hospitals and Fleets Henry Dawson Stanistreet has been placed on the retired list. Deputy Inspector-General of Hospitals and Fleets Richard William Coppinger has been promoted to the rank of Inspector-General of Hospitals and Fleets in His Majesty's Fleet.

The following appointments are notified:—Staff Surgeons: W. Bowden, D.S.O., to the *Naiad;* J. Chambers to the *Collingwood;* and W. M. Craig to the *Hibernia* for the *Maine*. Surgeons: P. T. Sutcliffe to the *Hibernia* for the *Maine;* W. J. Stitt to the R.M.A. Portsmouth; and N. H. Harris to the *Australia*.

ROYAL ARMY MEDICAL CORPS.

Temporary Lieutenant James C. G. Macnab, Surgeon-Captain 1st Fifeshire Volunteer Artillery, is granted the temporary rank of Captain whilst serving in South Africa.

The War Office have decided to enlist a certain number of trained men for service in the Royal Army Medical Corps during the present war in South Africa. Enlistments will be for the period of one year, or, if the war lasts longer, for the duration of the war. In the event of the war being over in less than one year they will have the option of being discharged at once, or of completing one year's service. They must be not less than 20 nor more than 40 years of age, and though there will be no maximum limit of height they must be medically fit for active service. A fair knowledge of ambulance and nursing duties will also be required of them. Married men may be accepted and facilities will be given when possible for their families to join them in South Africa on the termination of hostilities should they desire to remain in that country. All men accepted will be enlisted as privates and will receive a gratuity of £5 at the termination of their engagement, in addition to any gratuity given to the troops at the end of the war. The rate of pay will be 3*s*. a day.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Durham Light Infantry: Laurence James Blandford to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Cameronians (Scottish Rifles): John Marshall to be Surgeon-Lieutenant. 1st Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant A. E. Morison resigns his commission. 2nd Volunteer Battalion the Highland Light Infantry: Surgeon-Lieutenant A. N. McLellan resigns his commission.

VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Surgeon-Lieutenant J. W. Smith to be Surgeon-Captain.

YEOMANRY CAVALRY.

Royal 1st Devon: Surgeon-Lieutenant Henry Goodwyn resigns his commission and is appointed Lieutenant.

SOUTH AFRICAN WAR NOTES.

Lieutenant A. Chopping, R.A.M.C., has been discharged from hospital to duty.

Lieutenant Taylor is reported to be improving (Howick, March 18th.)

Major A. T. I. Lilly, R.A.M.C., is returning to England in the *Pinemore*.

THE HEALTH OF THE NAVY.

The report of the health of the navy just published is mainly statistical in character, being mainly made up of figures, returns, and tables, together with summary statements of deductions therefrom. But it contains in an appendix a selection of the more instructive reports which medical officers of the navy have furnished to the Admiralty. Among the most interesting of these is Surgeon J. G. Fowler's *résumé* of medical facts in connexion with the Naval Brigade at Ladysmith. The total number of deaths out of the Brigade of 284 men and officers was 37, and out of 19 officers 17 at different times were on the sick list.

The health of the navy, as a whole, during the year 1899 was good, and as the figures could not be more succinctly given than they are in the report itself we cannot do better than quote it.

The aggregate number of cases of disease and injury recorded for the year furnishes a ratio of 879·63 per 1000, which is the lowest obtained since the year 1856. Compared with the ratio for 1898, it shows a reduction of 26·46 per 1000, and with that of the previous two years a reduction of 20·82

All the stations, excepting the North America and West Indies, Pacific, and China, show a reduction in the ratio of cases as compared with 1898.

The invaliding ratio of the total force, viz., 27·64, also shows a reduction when compared with the previous year, and with the average of the last two years, in the former case of 1·22, and in the latter of 2·78 per 1000.

The death-rate per 1000 was 5·41 and shows an increase of 0·5 per 1000, as compared with that of 1898, which was 4·91.

129 cases of wounds in action are returned, 24 proving fatal. 117 of these occurred in South Africa and the remaining 12 during the Samoan troubles.

On the home station 11 cases of cerebro-spinal fever, all of which terminated fatally, are recorded.

Malarial fevers show a decrease, contrasted with 1898, especially on the Cape of Good Hope and West Coast of Africa Station, which shows a reduction of 170·46 per 1000 in the ratio of cases.

The ratio per 1000 of cases of primary and constitutional syphilis shows a reduction of 5·98 compared with the ratio for the previous year.

The total force in the service afloat, corrected for time, in the year 1899 was 89,180, of whom 54,880, or 61·53 per cent., were between the ages of 15 and 25; 25,270, or 28·33 per cent., were between the ages of 25 and 35; 7480, or 8·38 per cent., were between the ages of 35 and 45; and 1550, or 1·73 per cent., were 45 years of age and upwards.

The total number of cases of disease and injury entered on the sick list was 78 446, which is in the ratio of 879·63 per 1000, being a decrease of 26·46 per 1000 compared with the previous year, and of 20 82 per 1000 when compared with the average ratio of the last two years.

The total number of persons invalided was 2465, which is in the ratio of 27·64 per 1000, and shows a decrease of 1·22 per 1000 compared with the previous year. Of the above total 1760 persons were finally invalided from the service, giving a ratio of 19·73 per 1000 for the whole force, or 71·39 per cent. of the number invalided, showing an increase of 0·94 per 1000 compared with 1898.

The number of deaths was 483, which gives a ratio of 5·41 per 1000, and exhibits an increase of 0·5 per 1000 in comparison with 1898, and of 0·34 on the average of the last two years.

AFFAIRS IN SOUTH AFRICA.

The armistice with General Botha has, to the deep regret of most people, proved futile; it has led to no satisfactory conclusion. General Botha has informed the British Commander-in-Chief that his terms of peace cannot be accepted. The war, if war it may still be called, must therefore go on. The public and the military critic in this country wonder why it is not finished, but it is the hardest thing possible to track and to dispose of an enemy in a waste of veldt who never stays to fight and whose sole object is to make raids on the relatively weak posts scattered over vast lines of communications and then to disperse and reunite. But the systematic surrounding of large areas and sweeping-in process after the manner pursued by fishermen with their nets must tell in the end, however rarely we may inclose a great multitude of Boer fish. The plague is not making any very active progress at the Cape, but the continued and increased mortality among the rats has a nasty significance. Inoculation for plague is being extensively carried out, and has, indeed, been made compulsory. A large number of the native population have been camped out on the Cape flats and energetic attempts have been made to cleanse and to improve the sanitary state of some of the worst and most overcrowded districts. A case of bubonic plague has been found on board the *Roslin Castle* at Durban in the person of a trooper from Capetown and all precautions are being taken. We trust that the efforts of the charitable in this country will not slacken, for our troops in the field, owing to the stormy and wet weather, have been having a bad time

of it of late and they will soon be in need of ample supplies of clothing for the cold weather on the veldt.

THE BRITANNIA.

A medical board, consisting of Sir Henry Norbury, K.C.B., Director-General of the Medical Department of the Royal Navy; Dr. J. W. Fisher, Inspector-General of Hospitals and Fleets; Mr. A. W. May, Fleet Surgeon, R.N.; and Professor W. H. Corfield, Consulting Sanitary Adviser to His Majesty's Board of Works, have issued a report upon the recent sickness on board the training ship *Britannia*. The report finds the position of the *Britannia* in the mouth of the Dart salubrious and the wood of which the *Britannia* and the auxiliary ship *Hindostan* is built to be apparently quite sound, the air of the holds was sweet, and the bilges all that could be desired. The admissions on the sick list from diseases which may depend upon the sanitary condition of the ships have shown steady diminution during the past five years. From these and other circumstances the board have come to the conclusion as the result of their investigations that the recent outbreak of influenza among the cadets was introduced from without and had nothing whatever to do with the sanitary condition of the ships. Certain slight alterations in the ventilation and sanitary arrangements of the ship which the board have recommended are to be carried out at once so as to admit of the return of the cadets on March 30th. The Admiralty have made the report public to correct widespread but erroneous impressions.

WESTERN COUNTIES CONVALESCENT HOME FOR SOLDIERS, COMBE DOWN, BATH.

A meeting of the supporters of this institution was held recently at Bath under the presidency of the Mayor. General Ian Hamilton, C.B, gave an interesting address, and Colonel Steele, R.A.M.C., spoke of the admirable work that the home was doing. On the proposition of the Rev. Canon Quirk it was resolved that the home, which was established in January, 1900, and had rendered invaluable service to the soldiers, should be still carried on for at least another 18 months, and that £700 should be raised by subscriptions, which, with the amount already collected, will be required to maintain the convalescent home for that period.

THE PRINCESS CHRISTIAN COTTAGE HOMES FOR DISABLED SOLDIERS AND SAILORS.

A special appeal has been issued for the endowment of beds in these homes as a memorial to Prince Christian Victor. The homes are for men discharged from the army paralysed, crippled, or disabled and unable to earn their livelihood, and at the present time there are many sufferers from the South African and other wars for whom accommodation cannot be found. It is for those who are permanently disabled that provision is now required.

THE NEW MILITARY STATION HOSPITAL AT PORTSMOUTH.

The new military station hospital which is to be built at Portsmouth will be one of the finest institutions of the kind in this country. The hospital, which will be situated on an elevation of nearly 1000 feet above the sea level, will have a sea view on three sides, and will stand in grounds of about 40 acres.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—A meeting of the Northern and Midland Division of this association will be held at the Leicester and Rutland Asylum, Leicester, on Wednesday, April 3rd, 1901. Mr. Rothsay Stewart will read notes on "Two Cases of Insanity Following Chorea" and "A Case of Rodent Ulcer treated by X Rays." Dr. A. Miller (Hatton Asylum) will open a discussion on the Improvement of our Methods of Obtaining Information on Matters of Asylum Administration and the Advantages of Establishing a Bureau in connexion therewith. The asylum is about one mile from Leicester Station and Mr. Stewart invites members to lunch at the asylum at 1.30 P.M., when he will take them round the wards at 2.30. The meeting is fixed for 4 30 and there will be dinner at the Grand Hotel, Leicester, at 7.30, when morning dress will be allowed. Members intending to dine at the hotel and members accepting Mr. Stewart's invitation to lunch are requested to communicate by March 29th to Mr. Rothsay Stewart, County Asylum, Leicester.

Correspondence.

"Audi alteram partem."

PRINCE CHRISTIAN VICTOR MEMORIAL.

To the Editors of THE LANCET.

SIRS,—Will you allow us to appeal for assistance in carrying out the following project which was organised towards the close of last year?

The sympathy evinced by our lamented and revered Queen Victoria in all the personal sorrows of her people arising from the South African war had awakened a warm and grateful response in the hearts of the public, and it was then resolved to give expression to this all-pervading sentiment and in some measure respectfully to reciprocate the sympathy which had been shown by establishing a permanent memorial of the grandson of the Queen, Prince Christian Victor of Schleswig-Holstein, who died in the service of his country in South Africa.

Although the circumstances under which this tribute would have been paid are so sadly altered, the love and gratitude of the nation are only intensified, and the fact that our beloved Sovereign took the greatest interest in the proposed memorial and that it was one of her last wishes that it should be a success not only makes it impossible to withdraw the plan of a collection, which might otherwise seem inopportune at the present time, but adds a pathos to the appeal which cannot fail to insure its favourable reception throughout the country. It is proposed that the memorial shall take the form of a fund for founding and endowing beds in the Princess Christian Cottage Homes for Disabled Soldiers and Sailors. This would be in harmony with the spirit and aims of the young Prince who always had the interest of soldiers at heart.

Donations and offers of assistance in collecting may be sent to the honorary organising secretaries, office of the Prince Christian Victor Memorial, Horse Guards, Whitehall, S.W., or to the Memorial Fund at Messrs. Lloyd's Bank, 16, St. James's-street, S.W. Donations and collections will be acknowledged in the press.

We are, Sirs, yours faithfully,

(Signed) ROBERTS, F.M.,
President of the General Committee.

(Signed) REDVERS BULLER, Genl.,
Chairman of the Executive Committee.

Office of the Prince Christian Victor Memorial, Horse Guards, Whitehall, S.W., March 14th, 1901.

"THE DUTIES OF HOUSE SURGEONS AT THE EAST SUFFOLK AND IPSWICH HOSPITAL."

To the Editors of THE LANCET.

SIRS,—Allow me to thank you for your leading article in THE LANCET of March 16th and to suggest that the profession make a testimonial to the young surgeons who are suffering for making a most proper stand for the sacredness of knowledge obtained professionally. The public also have an interest in supporting those who suffer for maintaining that a surgeon is right to refuse to speak of what he learns of a person who comes under his professional care unless distinctly requested by the person concerned to do so.

If you will open a subscription list for this purpose I shall be happy to contribute two guineas and help in any way to maintain the doctrine that the press should seek information from *anyone* but a medical man professionally concerned, who is *the only* person bound not to know anything.

I am, Sirs, yours faithfully,

Framlingham, March 18th, 1901. GEO. E. JEAFFRESON.

To the Editors of THE LANCET.

SIRS,—In Dr. Kay's letter published in THE LANCET of March 16th, p. 816, there are two inaccuracies relating to me which, no doubt, were unintentional on his part but deserve correction. In my interview with the house surgeons I did not *demand* that they should see the reporters of this journal nor did I say that "the *paper* must be run." I asked that they would please see

the reporters or leave them the information, as previous surgeons had done, in order that accidents treated at the hospital could be reported, thereby bringing the benefits conferred upon the injured before the public as "the *institution* must be run." This paper does not depend for its existence upon the news obtainable from the hospital, but I believe that institution is largely benefited by the publicity the press gives to its work.

I am, Sirs, yours faithfully,

THE EDITOR OF THE "EAST ANGLIAN DAILY TIMES."

Ipswich, March 19th, 1901.

TO MEDICAL FREEMASONS.

To the Editors of THE LANCET.

SIRS,—May I through the medium of your valuable journal solicit the votes and interest of your Masonic readers on behalf of Doris Sall, aged nine years, daughter of E. W. H. Sall, M.R.C.S.Eng., till recently in practice at Southsea. He has been compelled to relinquish practice and to go on a sea voyage owing to the complete breakdown of his health, and is anxious to secure the election of his little girl to the Royal Masonic Institution for Girls at the election in April. Any votes will be thankfully received and acknowledged by

Yours faithfully,

J. ERNEST LANE,

Secretary, Sancta Maria Lodge, No. 2682.

46, Queen Anne-street, W., March 17th, 1901.

BENEFICIAL EFFECT OF OXYGEN IN PNEUMONIA.

To the Editors of THE LANCET.

SIRS,—I read the record of the case by Mr. A. Bradburne in THE LANCET of Dec. 15th, 1900, p. 1730, with much interest, as I thoroughly endorse his views on the benefit of oxygen in severe cases of pneumonia. The following occurred in a relative in my own home and was under my supervision continuously during the entire course. The patient was recovering from single lobar pneumonia when a relapse occurred, the disease breaking out afresh in the opposite lung. In spite of all treatment the patient got steadily worse and it was on a Tuesday afternoon the consensus of opinion of two medical men and myself that the case was practically hopeless—in fact, at the time the patient was almost moribund. The respirations were hurried and gasping, the lips were cyanosed, and none of us expected but that an hour or two would see the end. At this stage a tank of compressed oxygen containing 600 gallons, which had been ordered early in the morning, arrived (oxygen 79 per cent. and nitrogen 21 per cent., the exact opposite of the atmospheric proportion). I administered the gas for 10 minutes, when the respirations became normal, all cyanosis disappeared, and the patient sank into a quiet sleep, which she had not done for two days. In about 15 or 20 minutes the respirations began to quicken and the gas was applied to the nostrils, when breathing again became natural. In about another 20 minutes the patient awoke, said she that felt much better, and took some peptonised milk and champagne. For some hours previously all nourishment had been refused. The patients continued to improve, but the oxygen was administered day and night with no interval longer than an hour. At each administration the gas was stopped on the respiration becoming normal. For the first three days the improvement was marked. Food was taken with relish, even to a few raw oysters, which were longed for and given. During this time strychnine and digitaline were administered with brandy and champagne. On Saturday evening a change for the worse took place and the patient gradually failed. The oxygen was still kept up, and on the following Wednesday (eight days after the first administration) the patient died. Some hours before death she said that she felt something give way inside which on post-mortem examination was found to be an abscess of the left bases which burst into the peritoneal cavity. There is no doubt that this patient was kept alive for eight days by the oxygen, nine tanks of 600 gallons each being given during that time. This was a case of double pneumonia, the right lung being involved two weeks before the left. The patient also suffered for years from mitral stenosis and was very thin. Dr. H——, who had been in practice 50 years, said that he would always in future use oxygen in all severe cases of pneumonia, he never having seen it given so frequently before, and we three practitioners were unanimous in our opinion that the patient would have died that Tuesday afternoon but for the use of the oxygen. The oxygen was supplied by the Walton Company, New York city, where the case occurred. There it is always used mixed with 21 per cent. of nitrogen to 79 per cent. of oxygen, as in its pure state it is too irritating and cannot be administered but for a few moments, whereas the above mixture can be repeated as required with seemingly no bad effects when judiciously given. I have often had recourse to it and have yet to see the case where its effects were hurtful. Of course, it requires (like an anæsthetic) some practice to learn when to withhold and when to re-administer it. In 1898 a celebrated English author was taken ill with pneumonia in New York City. It was applied in his case and his condition to-day is only another proof of its benefit.

I am, Sirs, yours faithfully,

ARTHUR A. COTTEW,

L.R.C.S.I., L.R.C.P. Edin., M.D. Bellevue, New York.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—Dr. H. Laing Gordon's letter in THE LANCET of March 2nd is facetious but scarcely helpful. It may be a doubtful point whether "alcoholic nervous instability" can be transmitted from parent to child, but it is a fact that habits of intemperance in either parent tend inevitably to produce conditions which act unfavourably upon the children and interfere with the healthy development of both mind and body. I imagine that Dr. Gordon will agree that alcohol is capable of producing a condition of mental instability in those who, previously to their having acquired a taste for alcoholic drinks, were strong and healthy people, capable of reacting normally to their environment. Some time ago Dr. Pye-Smith pointed out to us that the cause of the nervous breakdowns we so frequently see in business men was not the wear and tear of work but the wear and tear of whisky. We have to recognise the fact that the public has a firmly-rooted belief in the general usefulness of alcohol both as a remedy in disease and as an article of diet. In all classes of society we constantly come across the idea that whisky is good for gout and rheumatism and that a mother cannot nurse her infant without the help of a plentiful supply of "nourishing" stout. For these ideas medical opinion in the past must be largely responsible, and if they are now proved to be false it is our duty to put the facts clearly and authoritatively before the public and insist upon having them included in the instruction given to the children in all our State schools, as I believe has been done in the United States with very encouraging results.

It may be true that legislation can never make a man sober, but, Sirs, I agree with you that a great deal can and ought to be done to prevent his drunkenness. The good results of shortening the hours for the sale of intoxicating drinks you, Sirs, have brought before us. There are two other reforms for which we, as medical men, might agitate—namely, the exclusion of children from public bars and the abolition of the office of barmaid. (In the United States women are not allowed to serve as barmaids and all attempts to introduce "real English barmaids" have so far been frustrated.) That the work of retailing intoxicants is as deadly as that of other occupations from which women have already been excluded by the State needs no demonstration.

I am, Sirs, yours faithfully,

London, W., March 6th, 1901. M.D., B.S. LOND.

THE HOUSING PROBLEM.

To the Editors of THE LANCET.

SIRS,—You have recently published four articles on the question of the housing of the working classes and the poor in London; the London County Council has issued a large volume containing particulars of its own work in dealing with the problem; the County Council was in December vigorously attacked by Mr. Charles Sheridan Jones in the *Fortnightly Review;* in the following month the chairman of the Housing Committee of the London County Council replied to Mr. Jones; and in the *Fortnightly Review* for February Mr. Jones returned to the attack. Those who have read your articles and those who in addition have digested the materials upon which they were founded or who have

otherwise studied the matter will be aware that the problem is already one of such magnitude that it may well seem to some insoluble, and that it does not diminish in difficulty because the influx of workers to London continues and because the poor displaced from insanitary areas never, apparently, find healthy dwellings erected for the accommodation of their full number to take the place of those pulled down.

The growth of the population and overcrowding perplexed Parliament in the days of good Queen Bess. In the thirty-first year of her reign it was enacted that no cottage should be erected in a rural district with less than four acres of land attached and that no cottage should be occupied by more than one family. This statute, typical of an age when all had elbow-room, stood till 1775, when it was repealed on the ground that it put the industrious poor in a difficult position and tended "very much to lessen population." Even in the reign of Queen Elizabeth London caused particular anxiety, for four years after the last Act mentioned was passed another forbade the erection of new buildings within three miles of London or Westminster or the conversion of one dwelling-house within the same area into more than one. This statute was only repealed by the Statute Law Revision Act of 1888, so that it must have been tacitly ignored for centuries—a parallel perhaps to the silent indifference with which more modern and more practical laws dealing with much the same subject have from time to time been treated.

It is not necessary to endorse all that Mr. Jones writes with regard to the County Council. Accusations not only of fatuity and ineptitude but of dishonesty and criminality, accompanied by comparisons with the methods of Tammany Hall, savour of vulgar abuse rather than of serious criticism, and it is easier to say that the London County Council might have done more than it has done than to define precisely the course which it ought to have pursued. Undeniably, however, the problem presented by overcrowding in London has been before the nation more or less prominently since Lord Ashley, afterwards more widely known as Lord Shaftesbury, drew attention to it in 1851, and very little has been *done* with regard to it, however much may have been suggested, or however much public bodies may have been empowered to deal with it. The County Council contributes its figures. The chairman of its Housing Committee says that Mr. Jones understates them, and taking them at their highest point they only show that the Council has re-housed between 20,000 and 30,000 persons, and as Mr. Charles Booth in his valuable statistical work ("Life and Labour of the People in London"), published in 1892, estimated the numbers of the lowest class of the population at 37,610, of the "very poor" at 316,834, and of the "poor" at 938,293, and as 128,000 families of from four to 12 persons live in single rooms it may be pretty safely assumed that what has been done does not substantially affect the mass of those living in insanitary conditions even if we add to houses and common lodging-houses directly due to the efforts of the Council those wholesome dwellings which have originated in private benevolence and private enterprise. The newly constituted borough councils of the metropolis may avail themselves, each within its own limits, of Part III. of the Housing of the Working Classes Act of 1890—that is to say, they as well as the County Council may acquire land and build houses for the working classes upon it and may possibly in years to come enjoy the privilege of being blamed if overcrowding still continues within their borders.

One thing before all must, however, be remembered by those who criticise the action of county council or borough council in availing itself of the powers given it (the exercise of which is optional) to expend or risk large sums of money in becoming the poor man's landlord. These bodies are representative, and elective, with frequently recurring elections. If county council or borough council declines to incur financial risks that are not compulsory, some part of the blame, if any there be, must fall upon the county or the borough at large. Mr. Jones who so freely censures the County Council might find no difficulty in securing election to it in a district deeply interested in its own insanitary condition, and yet might not be able to secure a majority of councillors elected from other districts of the great county of London to support such a programme of wholesale activity as he might successfully have laid before his own section of the electorate. Even if he secured such a majority he might still fail to gain the assent of the Treasury to the raising of loans on a scale of sufficient magnitude to give effect to his views.

It must be confessed that the outlook is not a bright one. Apart from other questions suggested the work to be done seems too great to be undertaken by the committees of councils which are composed of voluntary unpaid workers of varying degrees of intelligence, information, and zeal. Parliament has for the time shelved the question as far it concerns itself by giving certain powers to other bodies which they may or may not exercise. These bodies will have done something which they have not done yet when they have clearly shown that houses and lodgings for the poor can be provided and maintained under sanitary conditions so as to offer a small but fairly certain dividend upon capital supplied not for purposes of charity but as an investment, and a step will have been taken in the right direction when it has been proved by active enforcement of the law that the letting of houses under insanitary conditions is not only unprofitable but financially disastrous. Investors are satisfied with low rates of interest nowadays if their security be only tolerably good; the prices of scores of ordinary stocks of railways and commercial undertakings liable to grave fluctuations prove this. Where losses are made either by public bodies or private persons the transaction, if it continues at all, becomes one of charity and the housing of the poor of London by charity cannot be regarded as either desirable or practicable, however much charity may assist as a pioneer of the movement.

I am, Sirs, yours faithfully,

March 14th, 1901. INNER TEMPLE.

THE METHODS OF THE ANTI-VIVISECTIONISTS.

To the Editors of THE LANCET.

SIRS,—A few days ago I had the misfortune to lose a favourite cat and with a view to getting him back I inserted an advertisement in the daily press. On the evening of the day upon which the advertisement first appeared I received by post a large envelope addressed, "To the owner of the lost cat." The envelope contained a choice selection of literature which I forward for your inspection and which apparently emanates from the Surrey Branch of the British Union for the Abolition of Vivisection. The first document I looked at was headed, "The Climax of Human Selfishness," and I own I was puzzled, for I could not see that it was selfish either to keep a cat or to lose him. I read on and came to a leaflet entitled "Enteric and Typhoid in South Africa." Still I was unenlightened, but I looked further and came to sundry pamphlets, in which were quoted experiments by Mr. Frederick Treves, Mr. Walter Edmunds, and Dr. Rose Bradford. Then it flashed across me that the B.U.F.T.A.O.V. wished to convey to my mind that some, or all, of these eminent men of science had presumably stolen my cat for the purpose of experiment. I can draw no other inference from the contents of the envelope, and I have sadly come to the conclusion that Mr. Treves is at fault. When he was away in South Africa the cat was safe. On his return the cat disappears. Comment is needless. My argument may not perhaps stand strict examination by the laws of the syllogism, but it is quite as convincing as the following argument which you will find in the leaflet entitled "Enteric and Typhoid in South Africa." Concerning antitoxins the pamphlet says: "To show the absurdity that prevails, diphtheria antitoxin is made by passing it through the horse. *The horse never has diphtheria.*"

I am, Sirs, yours faithfully,

March 15th, 1901. M.B.

PS.—The cat has come back. He has a scratch under his chin and a bald spot on the back of his head. I am waiting to see what fell disease will develop.

"THE ROYAL ORTHOPÆDIC HOSPITAL."

To the Editors of THE LANCET.

SIRS,—The letter published in THE LANCET of March 9th, p. 739, from a governor of the Royal Orthopædic Hospital told a strange tale, but during the week that followed events have taken place which enable me to tell a stranger and more startling story.

On March 14th—I have it on the best authority—a small committee meeting was held at the hospital. Without previous notice an offer of £37,700 was

brought forward. Two members voted in favour of accepting the proposal, two against, when the chairman, Mr. Ernest Flower, M.P., at once gave the casting vote in favour of sale. The sum of £37 700 means the sale of the hospital on a basis of 29 years' purchase at a rental of £1300. At the general meeting on Feb. 18th Mr. Marks stated the value of the hospital was 30 years' purchase at £1500, or a sum of £45 000.

Will it be believed that at the committee meeting on March 14th, when it was decided to sell for £37,700, an offer was actually laid before them to rent the Hanover-square end of the hospital property at £1200 a year on lease? That would leave the more valuable Oxford-street end of the premises free for further letting. For the purpose of argument let us assume the Oxford-street end let on lease also at £1200, though £1500 is nearer its value, that would mean a yearly rental of £2400, or, capitalised at 30 years' purchase, a value of £72,000. This is probably not far off the present value of the property which the committee decided to sell for £37,700. Fortunately the Charity Commissioners have a right to intervene and it is to be hoped they will satisfy themselves of the facts above stated.

What should we think of gentlemen who dealt with their own property in such a way? Mr. Marks turned out the former committee because they wanted to sell the site for £28,000. His committee suddenly reversed that policy and have now determined to sell for £37,000. Mr. Marks ousted the old committee by votes that were by his own admission those of governors created for the purpose. He has largely relied on those votes for obtaining fuller powers at the annual meeting of Feb. 18th last. Surely, he should, under such circumstances, take no steps in the sale without the fullest deliberation and publicity.

It is to be hoped that in the interests not only of an old-established hospital, but also of the whole cause of the medical charities, that publicity will be given to the series of transactions that have been taking place at the Royal Orthopædic Hospital. At the same time one may hope that THE LANCET will insist on an explanation from the Prince of Wales's Fund why they wished to force the Royal Orthopædic Hospital to sell the site. At the time when they urged that course it was actually proposed to accept £28,000 for the property. Did the Fund investigate the facts of the case before they accepted the serious responsibility of urging such a step? Happily, in these days the bar of public opinion is still a force in the land. I trust that THE LANCET may inform the public as to the unbusiness-like and unwise policy now being pursued by Mr. Marks and his friends at the Royal Orthopædic Hospital.

I am, Sirs, yours faithfully,

March 19th, 1901. HOSPITAL GOVERNOR.

THE ORGANISATION OF THE PROFESSION.

To the Editors of THE LANCET.

SIRS,—Perhaps it is not generally known that some of the large colliery sick clubs are endeavouring to impose on their surgeons that they should attend on obstetric cases for a fee of 10*s*., instead of the recognised £1 1*s*., which in all justice is small enough. It is about time that these unreasonable conditions should be erased from all contracts. I am quite sure that all we require is combination and fair discussion with selected committees from each side.

I am, Sirs, yours faithfully,

March 15th, 1901. A GENERAL PRACTITIONER.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

THE one hundred and twenty-first annual meeting of the supporters of this hospital was held on March 20th. The report for 1900 dwells upon the loss by death of Sir John Jaffray who for 30 years was a member of the committee and gave valuable help in the management. Reference is made to the large number of enteric fever cases treated in the hospital; a limit of 36 beds was assigned last year to patients suffering from this disease, but this number is greatly inadequate, the list of those awaiting admission often exceeding 100 and rarely dropping below 50. There is every probability of the health committee aiding in the effort to deal with these cases by the opening of additional hospitals. The report further shows that the number of patients was 5211, an increase of 347 over the previous year. The out-patients were 60,866, or 238 more than in 1899. The number of operations is shown to be steadily increasing; thus in 1897 there were 1020 and in 1900, 1815. The financial record shows an adverse balance of £6291, the average income for the last three years being under £22,000 and the average expenditure over £24,000. An urgent appeal is being made for additional subscriptions to carry out the needs of the hospital and to obviate the curtailing of its beneficent work.

A Singular Case of Manslaughter.

At the recent assizes, held on March 18th, before Mr. Justice Ridley, a man was indicted for manslaughter under exceptional circumstances. Two men quarrelled, both being intoxicated, and the prisoner struck the deceased a blow in his left eye. The following day, his eye being painful, he was taken to the Eye Hospital and detained. It was found that the eyeball had been burst and an operation to remove it was necessary. Chloroform was administered by the resident medical officer at the hospital, but the man died during the operation. The judge remarked that the crime was manslaughter in law and that the cause of death was the blow and not the operation. The prisoner was sentenced to one week's imprisonment, to date from the commencement of the assizes; consequently he was liberated on the following day.

The Consultative Institute.

Dr. Ward Irvine, who resigned his post at the beginning of the present month, severs his connexion with this institute on May 21st. In the meantime there is an opportunity for an amicable understanding and a settlement upon just grounds of the differences at issue. At a recent meeting of delegates from the Hospital Saturday Fund Mr. Arthur Chamberlain remarked that the Consultative Institute had justified its existence and would go on. If it does it must go on under its true colours. It is useless to associate the scheme with philanthropic disguises or to speak of the dignity and self-respect of a certain class of the population. It is generally found that in a large city like this the inhabitants are sufficiently astute to protect their own interests apart from the sentimental considerations of self-elected patrons.

March 19th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Sale of Drink to Children.

THE Prestwich District Council, on the recommendation of the health committee, at their last meeting authorised the affixing of their seal to a memorial to Parliament to prohibit the sale of drink to children under 16 years of age. The Chorlton Guardians likewise have decided to support this memorial and to write to the Members of Parliament for Manchester asking them to support the Bill. The Salford School Board also are sending a petition to the House of Commons in favour of the prohibition of the sale of intoxicants to children under 16 years of age.

Police Ambulance Work.

On March 14th an interesting ceremony took place in the Manchester Town Hall. The Lord Mayor, in the presence of many members of the corporation, presented 267 medallions and certificates gained by members of the police-force for proficiency in ambulance work. Alderman Rawson, the chairman of the watch committee, proposed a vote of thanks to the mayor and pointed out that 828 members of the force held certificates from the St. John Ambulance Association while the force had rendered first aid in a great number of cases "many of which would have proved fatal had it not been for the prompt measures taken by the police. During the last five years 10,570 persons had been taken to the infirmary and other similar institutions or to their homes and 52 lives had been saved." Dr. G. H. Darwin, who has long taken a deep interest in the subject, seconded the vote of thanks and said that "ambulance work was next to godliness, it was a noble work"; and he has certainly acted up to his view and worked nobly for it.

Eating-Wagers.

Wagers of a specially disgusting character have become so common in this part of the country that they may

almost be said to be epidemic. The favourite subject just now is as to the ability to eat a pigeon a day for 14 days. It is popularly supposed that it takes 24 hours to digest one pigeon and that it is too great a trial to the stomach for it to endure 14 pigeons in 14 consecutive days. The imagination of the lower—i.e., of the more animalised—classes, which is much centred on the stomach, has been stimulated to a marvellous degree by these competitions. The "well-known publican," who is also a "familiar figure in football circles," encourages them, of course, because they bring together numbers of people who wish to see the pigeon-devouring hero, and the sight induces a great thirst. One of these men on the Saturday night before he ate his first pigeon devoured "one sheet of a popular football paper," and some three or four years ago this same man and a companion had a paper-eating contest which he won. The political views which he inwardly digested are not stated. He was to eat his last pigeon on Sunday night, March 17th, and was feeling so well that he asked for a brace of them to commemorate the occasion. That this kind of thing should be the pride and ambition of so many does not say much for the refining influence of the education about which such a parade is made, for the competitors in this high-class sport have, no doubt, gone through their "standards" in the regularly prescribed fashion. If so the best result of our system of education seems to be that it does not impair the appetite or enfeeble the digestion. The worst feature of the whole thing, perhaps, is the publicity given to such contests by a certain section of the press which panders too much to vulgar grossness of taste.

Schools for Feeble-minded Children.

In connexion with the School Board system for Manchester there is one matter in which all will agree. As is well known, among the thousands of children to be taught a certain number are more or less feeble-minded and unfit for the ordinary course of school work. It is therefore satisfactory to know that two schools are now being built with special provision for the needs of these children, one for 46 scholars and the other for 80 scholars. They are, like those in London and elsewhere, all on the ground floor, with separate entrances for boys and girls, with bathing accommodation and with everything necessary for the special requirements of these poor children. It is said that there are about 1000 of them in Manchester, so that more provision will have to be made.

March 19th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox at Cardiff.

THREE cases of small-pox were found on March 15th in a seamen's lodging-house in Cardiff. The patients, a sailor, a girl aged 14 years, and a boy aged four years, were removed to the small-pox hospital, where the sailor died on March 18th. The outbreak can be distinctly traced to cases which were removed from two ships at Barry about the middle of February.[1] A sailor from one of the infected vessels went to stay at the Cardiff lodging-house until Feb. 25th, when he left apparently well to join his ship, but as his papers have been returned it is possible that he has been attacked with some form of illness. Within a fortnight from Feb. 25th a sailor who has since died and the two children were attacked. The health committee are displaying commendable energy in their efforts to prevent the spread of the disease, spurred on possibly by the fact that the Royal Agricultural Show is to be held this year at Cardiff. Placards offering free revaccination are distributed and domiciliary visits of the public vaccinators are being made; while the inmates of the infected lodging-house and of the house where the infected girl was in service are both placed under observation. The corporation has not yet provided any house or houses into which persons who have been exposed to infection can be removed until the period of incubation has expired.

Port Sanitary Expenses.

The health committee of the Bristol Corporation have decided to renew their efforts to induce the Government to pay out of the Imperial exchequer the expenses incurred by port sanitary authorities in taking precautions against the introduction of cholera, plague, and yellow fever, on the ground that such expenses are incurred for the protection of the country at large.

Bristol Royal Hospital for Sick Children and Women.

This hospital was established in the year 1857 and has now, in addition to the 100 beds in the Bristol institution, a convalescent branch at Weston-super-Mare with accommodation for 28 patients. At the annual meeting of the supporters of the hospital held on March 16th it was stated that the income for the year (£3875) fell short of the expenditure by about £800. The accumulated deficits of the past few years have now reached £2300, an amount which it is hoped will be realised from a bazaar to be held in May. The number of in-patients treated during the year (631) was rather less than in some previous years, and the number of out-patients (4223) was considerably higher. In the dental department 450 patients were treated.

Bristol General Hospital.

At the annual meeting of the supporters of this institution, held on March 11th, it was announced that the following scholarships had been awarded: Clarke Surgical Scholarship of £15 to C. Corfield, Henry Marshall Prize of £11 to J. E Sparks, Lady Hoberfield Prize of £29 to A. E. Iles, and the Martyn Memorial scholarships, £15 to S. R. Williams and £5 to J. C. Norton.

Monmouthshire County Asylum.

At the meeting of the Monmouthshire County Council, held on March 13th, it was decided to erect a pathological laboratory and make other alterations in the asylum at Abergavenny at an estimated cost of £3000.

March 18th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Glasgow.

THE new cases admitted to hospital during the week ending March 17th numbered 92, and the cases remaining under treatment amounted to 420. In his report to the corporation Dr. A. K. Chalmers discusses the increase in the extent of the epidemic which has developed since Feb. 19th, and concludes that some influence which cannot be precisely determined led to an active dissemination of the disease at the end of the first week of February, and that the operation of this new factor was probably favoured by the seasonal conditions under which it occurred. In view of some efforts which have been made to discount the value of revaccination the medical officer states that no case of the disease has been admitted to hospital or is known to the health department in which revaccination had been performed before the disease was contracted. At the last meeting of the town council an attempt was made by one of the members to controvert this statement, but the Lord Provost insisted on its accuracy and drew attention to its public importance. The health committee has expressed satisfaction with the efforts that are being put forth to deal with the epidemic which still, as the above figures show, continues to give ground for anxiety. The scheme for securing a medical house-to-house visitation is being energetically prosecuted, more than 200 practitioners having responded to the invitation of the corporation to assist in securing effective revaccination for all citizens. A circular has also been issued to employers of labour throughout the city requesting them to use their personal influence with their workmen to promote revaccination. Some of the critics continue to call for a detailed report on the vaccination condition of all patients treated during the epidemic, but the pressure on the health officials renders this impossible, and an official statement has been made that such a report cannot be issued until the epidemic is thoroughly under control.

Glasgow University.

The meeting of the University Court on March 14th was occupied by a long and important discussion on the subject of clinical teaching and examinations Dr. D. C. M'Vail, seconded by Sir John Cuthbertson, proposed that the court should invite the physicians and surgeons of the Royal Western and Victoria infirmaries to become examiners in the University. The avowed object of this proposal was to induce

[1] THE LANCET, Feb. 16th, 1901, p. 514.

the University students to take at least part of their clinical work in the Royal and Victoria infirmaries. Dr. M'Vail argued that the clinical classes of the university professors are much overcrowded whilst other clinical teachers are to a large extent neglected. This state of matters, he contended, is due to the fact that the professors have a predominating influence in the degree examinations. The various physicians and surgeons are already recognised as teachers whose classes qualify for graduation, and in order to promote a more equal distribution of students and to make clinical teaching more practical and effective he proposed that all these gentlemen should take part in the professional examinations for degrees. The Senate, who had been asked to report on the proposal, advised against it and an amendment adopting the view of the Senate was moved by Professor Adamson who expressed his sympathy with the desire to secure the clinical facilities of the several hospitals for the benefit of the students. He, however, refused to believe that the large attendance in certain classes was to be explained by the mere fact that the teachers were also examiners. He opposed Dr. M'Vail's proposal on the ground that its adoption meant the transference of the appointment of examiners from the University authorities to the governing boards of the hospitals. Whilst willing to consider any reasonable plan for restricting the size of clinical classes he could not assent to a scheme which would remove the control of the University from examinations which admitted to a university degree. On being put the amendment was carried by 5 votes to 4.—The Senate have resolved, at the graduation ceremony in April, to confer the honorary degree of LL.D. on Mr. Andrew Cecil Bradley, M.A., formerly Professor of English Literature in the University; Mr. Charles Scott Dickson, K.C., M.P., Solicitor-General for Scotland; and Dr. Arthur William Rücker, F.R.S., secretary of the Royal Society. From some statistics recently collected it appears that since women were admitted to graduation in the University 49 have taken the degree of M.A., 15 with honours, four have graduated in the science faculty, and 52 have taken the degrees of Bachelor of Medicine and Bachelor of Surgery. The special organisation and facilities provided at Queen Margaret College are evidently appreciated, as Glasgow can claim more medical women graduates than can any other Scottish University.

Meat Inspection in Glasgow.

A special committee of the town council has reported that in addition to the detective system of meat inspection at present in operation in the city it is necessary for the security of the public health to make further regulations for the examination of meat which is to be offered for public consumption. The committee advises the provision of suitable and convenient premises for such inspection and favours the proposal to provide some form of marking or stamp for meat which has been approved, so that firms using meat in large quantities may have a ready guarantee that no diseased meat passes into their premises. The need for some effective supervision is emphasised by a recent case in which the owner of a condemned carcass actually produced a certificate from a local veterinary surgeon stating the meat to be fit for human food, though on cross-examination he admitted that he was aware that the animal was diseased.

The late Dr. James Dunlop.

By the death of Dr. James Dunlop, a well-known figure has been removed from the medical world of Glasgow. Dr. Dunlop had reached the age of 67 years and had been engaged in active practice since he graduated at the University of Glasgow in 1857. His earliest experience was gained as house surgeon to Lord Lister in the Royal Infirmary, and almost from the outset he devoted his chief attention to surgical practice. At an early age he became Professor of Surgery in Anderson's College Medical School, a position which he held for more than 20 years. Until he retired a few years ago he also held the position of senior surgeon to the Royal Infirmary. For many years he displayed a keen and enthusiastic interest in the medical branch of the volunteer service; his first commission was dated November, 1860, and in 1890 he became Brigade-Surgeon-Lieutenant-Colonel to the Glasgow Brigade. Advancing age hardly checked his devotion to this work, and in January of last year he went out to South Africa, where he was appointed one of the surgeons to the Wynberg Base Hospital. His return in August was celebrated by a banquet, at which he gave a lively and incisive account of his experiences. In addition to his connexion with the Royal Infirmary, Dr. Dunlop was surgeon to the Lock Hospital and a governor of the Samaritan and Victoria infirmaries; in the promotion of the last-mentioned institution he took a prominent part. He was also for many years medico-legal adviser to the Crown, and in this capacity his name has been associated with many of the great criminal trials of the last generation. His other professional positions were largely connected with the Faculty of Physicians and Surgeons, in which he held at different times various offices, including those of examiner and visitor. To many Dr. Dunlop was known as an ardent sportsman and naturalist, and his letters descriptive of his fishing holidays on the Scottish coast contain many valuable observations on natural history and have a full measure of the saving salt of humour. Possibly Dr. Dunlop was concerned in too many directions to obtain great excellence in any, but his force of character secured wide recognition and his genial and kindly disposition made for him a wide circle of appreciative friends. Dr. Dunlop is survived by his widow, six sons, and one daughter; one of the sons is at present serving as a civil surgeon with the army in South Africa.

March 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Health of Dublin.

THE above title is almost paradoxical. The exceptionally high death-rate which has recently been notified in Dublin has caused much comment in the public journals and many letters and suggestions from the citizens. The wretched and overcrowded state of the tenement houses has long been looked upon as a foremost factor in the spread of disease. The matter is dealt with in a letter from Sir Charles Cameron in the *Irish Times* of March 19th, which contains some interesting statements and figures. The evil of overcrowding, he says, does not now largely exist, for the census which has just been taken in reference to the dwellings of 15,000 families occupying the lowest-class houses shows that the number of persons in those houses is in the ratio of 2·5 per room. This is a great improvement on the state of things disclosed by a similar census in 1881 when it appeared that 32,000 families occupied 48,000 rooms, or one family per one and a half rooms.

The Irish Workhouse Association.

The annual meeting of the Irish Workhouse Association took place in the Mansion House on March 8th and was to a large extent a medical function. The Right Hon. Lord Monteagle, K.P., the President, occupied the chair, and resolutions were proposed by Dr. T. Myles, President of the Royal College of Surgeons in Ireland, Sir William Thomson, Sir Philip C. Smyly, and Colonel Everard, D.L. Public attention was called to the fact that although the association has been but a comparatively short time in existence it has been the means by which a great deal of good has been effected. One of the speakers remarked that if the association had done nothing beyond inducing the Government to pay half the salaries of the trained nurses in workhouse hospitals it would have fully justified its existence. Sir William Thomson said that he was delighted to notice in the report that the Government had consented to a reform, and that the first step had been taken in the appointment of a medical inspector whose duty it would be not alone to look after the buildings, but also to see that the infirm and sick were taken the best possible care of.

The Royal College of Surgeons in Ireland.

At a meeting of the Fellows of the Royal College of Surgeons in Ireland on March 19th, Sir William Thomson and Mr. Robert H. Woods were elected members of the council to fill two vacancies.

The Royal University of Ireland.

A deputation from the Royal University of Ireland waited upon Earl Cadogan, the Lord Lieutenant of Ireland, on March 9th, for the purpose of requesting the appointment of a Royal Commission to inquire into the working of the Royal University as an examining and teaching body in relation to the educational needs of the country at large. After several members of the deputation had spoken his Excellency made a very conciliatory reply and stated that he had brought the matter before the Cabinet and that a Royal Commission would be appointed. Of course, a great deal will now depend

on those who may be appointed on this body, but as the Commission is a Royal one it is expected that there will be members from other parts of the United Kingdom than Ireland; indeed, many think it would be wiser to appoint no one from Ireland on it as sectarian and political bias is so rampant in this country at present, even in educational matters.

Ulster Medical Society.

The fifth meeting of the session of the Ulster Medical Society was held in the Physiological Laboratory, Queen's College, Belfast, on March 15th, the President, Professor W. H. Thompson, being in the chair. The President showed a convenient form of Kjeldahl apparatus for estimating the total amount of nitrogen and a new apparatus for making standard alkaline solutions. Dr. Robert Allen gave a demonstration of Microscopic Sections of Granular Cells in Tumours. Professor J. Symington gave a lantern demonstration of the Pre-natal and Post-natal Development of the Cerebral Hemispheres. Dr. R. J. Johnstone gave a demonstration of a series of pathological specimens mounted dry with glycerine in the lower part of the jars, which were hermetically sealed. Professor J. Symington and Dr. J. A. Craig showed (1) a specimen of Hypertrophy of the Nasal Turbinals (with lantern slides); (2) specimens of Cæca and Vermiform Appendices; (3) a Skull with Defective Tegmentum Tympani; and (4) an Impacted Fracture of the Neck of the Femur. Professor J. Symington and Dr. J. Tennant exhibited a Section of a Female Pelvis containing a Tumour. Dr. J. Lorrain Smith and Mr. Robert Campbell showed (1) a Congenital Cystic Sarcoma removed from a child three weeks old, and (2) a Sarcoma of the Upper Third of the Femur of a Child. Dr. Thomas Houston read a paper on Anæmia in a Case of Typhoid Fever. He first pointed out that enteric fever was one of the few septic conditions of the blood in which the number of leucocytes per cubic millimetre were decreased; that this decrease was due to an "apparent" decrease of the polymorphonuclear elements. The differential counts made in this case showed a high percentage of lymphocytes and large mononuclear leucocytes. The usual explanation of this disease as given by Ehrlich and others is that the toxins of the typhoid bacilli repel the polymorphonuclear elements (negative chemotaxis). The reader went on to adduce evidence from the determinations made in this case that this theory of negative chemotaxis was not applicable to typhoid fever. He showed that there were many reasons for believing that in typhoid fever there was a tendency to dilution of the blood and that this tendency would fully account for the peculiarities of the blood as illustrated by the differential counts given. He quoted a case of typical chlorosis which had apparently been set up by typhoid fever, and he pointed out that this disease was also one in which there was a marked dilution of the blood, as shown by the work of Dr. Lorrain Smith on Anæmia. The blood determinations illustrating the paper were those of patients in the Royal Victoria Hospital, Belfast. An interesting discussion followed in which the President, Dr. Lorrain Smith, Professor J. A. Lindsay, Dr. W. Calwell, and Colonel J. Moorhead took part.

Agmondisham B. Vesey, M.R.C.P. Irel., J.P.

I regret to announce the death of Mr. A. B. Vesey of Magherafelt, co. Derry, a practitioner who was much respected in the north of Ireland. On the evening of March 12th, while proceeding on his way home from the dispensary situated a short distance from his residence, he fell suddenly in an anginous attack and expired. During the past 12 months Mr. Vesey has been in declining health and in August, 1900, he was compelled to relinquish his duties as medical officer of the dispensary and workhouse for six months, and this leave of absence was further extended at the last meeting of the board of guardians. Mr. Vesey studied in Dublin, at the Richmond Hospital. He qualified in 1873 and was a Member of the Royal College of Physicians of Ireland and a Licentiate of the Royal College of Surgeons in Ireland. Returning to his native place, Magherafelt, where his grandfather was rector, he succeeded his father as medical officer of the workhouse and dispensary, and as physician to the fever hospital. Mr. Vesey was greatly respected by both rich and poor, who had the utmost confidence in his professional skill, and his sudden death is universally deplored. He was a J.P. for the county of Derry. He was buried on March 15, a large concourse of patients and friends following his remains to their last resting-place.

Samuel Doake, M.A., M.D. R.U.I.

I regret also to chronicle the death of a distinguished former student of Belfast, Dr. S. Doake, which occurred at his residence, The Hill, Dromara, co. Down, on March 14th. A very able student during his Queen's College course, Dr. Doake graduated M.D. of the Old Queen's University in 1862. He then entered the army, but residence in India so broke down his constitution, which was never a robust one, that he was obliged to retire on half-pay. Coming home he was appointed medical officer of the Dromara Dispensary, but this office he had to relinquish owing to ill-health. Since then he has lived in retirement with his children at The Hill, the house in which he was born. A great personal favourite, and a man of thorough ability, Dr. Doake was always handicapped by a weak physique. He was buried on March 16th.

March, 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Legal Action on Account of X-Ray Burns.

THE Civil Tribunal of Paris has just given judgment in a case which lasted for some time and which raised an interesting point as to the responsibility of a medical man. A lady named M—— prosecuted a medical radiographer for having, as she alleged, committed an error in having injured her by burns produced by the x rays. Madame M—— had suffered for some years from acute sciatica and on the advice of her family medical attendant she had consented to have her leg radiographed by Dr. B——, who gave her three sittings. The first lasted 40 minutes, the second 45 minutes, and the third one and a quarter hours. Before this last sitting the skin of Madame M——'s thigh was noticed to be somewhat red and inflamed from the preceding sittings. But although Madame M—— mentioned this Dr. B—— made light of it and went on with the third sitting of one and a quarter hours, at the end of which time Madame M—— had a burn of the third degree which confined her for four months to her bed. On this account she claimed 5000 francs damages from Dr. B——. Dr. Brouardel and M. Ogier, who had been nominated as expert witnesses by the tribunal, sent in a very remarkable report according to which Dr. B—— was not responsible for the damage. In their views the method of application in radiography is not yet formulated and no one knows the conditions which give rise to the fact that some patients are burned while others with even longer exposures are unhurt. In the same way it is impossible to foresee out of a body of men marching in the sun who will be affected by sunstroke. It was, however, to be regretted that Dr. B—— did not pay attention before the commencement of the long third sitting to the inflammation which had appeared after the second sitting. Despite this definite report the court gave Madame M—— the full damages asked for—namely, 5000 francs—declaring that Dr. B—— had acted imprudently, more like a workman than a medical man, and that his apparatus was defective. This judgment, however, is subject to appeal.

Subcutaneous Injections of Chaulmoogra Oil in Leprosy.

M. Hallopeau and M. du Castel have made known to the Academy of Medicine some results, founded on some researches of Tourtoulis Bey, which they had obtained in cases of leprosy by the use of chaulmoogra oil given by subcutaneous injection. If given by the mouth the drug was often badly borne and so its use had to be given up too soon, for it is a remedy which has to be employed for a long time to do any good. M. Hallopeau remarked that from the composition of the oil not being exactly known it was often supplied in an adulterated condition whence the variable results and often-times the ill success obtained in the hospitals by this treatment. When the subcutaneous injections were well borne they gave in certain cases excellent results and even brought about apparent cure, but it must be remembered that cases of leprosy often underwent unexpected and spontaneous amelioration and that the injections were sometimes very badly borne. M. du Castel said that he had obtained good results in the tubercular form but practically no result in the nervous form. In his opinion the treatment should be reserved for the grave cases, for it was painful and like all oily injections was wont to produce, despite every precaution, painful abscesses or pulmonary embolism.

Alterations in a Water Service by a Landlord.

M. Bechmann, the Director of the Municipal Water-supply, has just brought before the Council of Hygiene the case of a landlord who had two concessions—the one for the supply of spring water for his kitchens and water-closets on the various floors of a tenement house and the other of river water to supply the public standpipe in the yard. From motives of economy he inverted his supply, so that the kitchens were supplied with river water and the tenants were compelled to go down to the yard to get drinking water. In the existing state of the law the administration is powerless to compel the landlord to reconvert his supply and the only thing to be done is for the tenant to bring an action in the civil court. M. Bechmann demands that the law which presents such glaring deficiencies should be altered.

Small-pox Inoculation in Algeria.

M. Hervieux recently drew before the Academy of Medicine a very sombre picture of the danger to which small-pox inoculation is giving rise in Algeria. According to a report by M. Trolard this abominable practice is making headway more and more among the natives. They refuse vaccination, despite all the efforts of the medical men, and prefer direct small-pox inoculation performed by native practitioners who inoculate with a lancet charged with variolous pus. Owing to this deplorable habit, which the French authorities try in vain to combat, small-pox is increasing rapidly among the Arabs and the mortality is going up, to say nothing of the numbers of maimed and blind who have to be looked after by the State, while as a final result the commercial relations of the colony are beginning to be imperilled. M. Hervieux argued that energetic measures must be taken and proposed that the Academy should lay down a rule that inoculation should be made a penal offence punishable by a fine in every French colony. A discussion, however, took place, M. Chauvel saying that the Academy could not formulate penal laws without going outside its proper rôle, which was advisory and scientific. M. Gautier considered that a fine was an insufficient punishment and suggested that compulsory isolation of small-pox patients, which being at once a kind of imprisonment and a valuable method of prophylaxis, would have greater weight in the eyes of the natives. Finally, the Academy left the choice of the punishment to the Minister concerned but insisted that small-pox inoculation ought to be sternly suppressed in French colonies.

The Title of Doctor of Pharmacy.

When some three years ago the responsible Minister created the new title of "Doctor of Pharmaceutical Science" there were not wanting many medical men who expressed a fear that this new diploma, which was intended to encourage higher education and study of pharmacy with a view to the student seeking a professorship or the post of expert, would also encourage the illegal practice of medicine already so largely indulged in by pharmacists, for the public, which considers that the term "doctor" means doctor of medicine, would be confused. At the time that the title was proposed the council of the University of Lyons reported very unfavourably upon the idea, but nevertheless the title was created. However, it was expressly laid down that the holder of the new title should not call himself simply "doctor" but always "doctor of pharmacy." All the same, that which had been foreseen happened and the new doctors constantly forgot to add the words, "of pharmacy." The President of the Association of Medical Men of the Seine made a formal representation to the syndical Chamber of Pharmacists in order to bring about the cessation of the abuse, but the pharmacists evaded the question, declaring that their Chamber had nothing to do with such matters. The President of the Association of Medical Men then applied to the responsible Minister and received the answer that in future the new doctors would be definitely instructed to use the precise terms of their diploma so that, in showing its purely academic character, all confusion with the title borne by practising physicians would be avoided.

March 19th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Death of Dr. G. M. Dawson.

DR GEORGE MERCER DAWSON, C.M.G., LL.D., A.R.S.M., F.R.S., &c., who for many years had been director of the Geological Survey of Canada, died in Ottawa on the afternoon of March 2nd from acute bronchitis and *la grippe*. He was born at Pictou, Nova Scotia, on August 2nd, 1849, and was a son of the late Sir William Dawson, F.R.S., who for many years was the principal of McGill University. Dr. Dawson's work was mainly carried on in the North-West Territories of the Dominion of Canada and in British Columbia, where he investigated more particularly the relations of the cretaceous and the Laramic formations. He further contributed largely to our knowledge of the glacial phenomena which in Canada are so strikingly developed. In 1891 he was appointed one of Her Majesty's Behring Sea Commissioners and for his services in this connexion received the title "C.M.G." He was President of the Royal Society of Canada in 1894, and in 1897 he received a gold medal from the Royal Geographical Society, a well-deserved honour.

The Latest News from the Yukon.

During the months of January and February the residents of Dawson experienced some very severe weather. The lowest temperature recorded was that on Jan. 15th, when the thermometer descended as low as 68·5° F. below zero. For nine days the average minimum temperature was 60° below. With the onset of the intense cold that peculiar white mist which always accompanies it settled slowly down upon the city and valley until an object could scarcely be distinguished 50 yards away. To add to the discomfiture of the inhabitants an epidemic of rabies seized upon the dogs of the town, which became so widespread and alarming that they all had to be impounded for the protection of society. Then what might be called an epidemic of "typho-pneumonia" broke out and carried off many prominent and popular citizens. The pneumonia appeared first and developed after the usual fashion. Then as the crisis approached abdominal complications set in, resulting eventually in a fatal collapse. During the months of December, January, and February the death-rate from "typho-pneumonia" was extremely high.

Report on Leprosy in Canada.

In the annual report of the Minister of Agriculture appears the regular report of the officer having the medical supervision of the lepers at the Lazaretto, Tracadie, New Brunswick, Dr. A. C. Smith. From this it appears that there are to-day in that institution 20 inmates—13 males and seven females—whose ages range from 19 to 64 years. Seven of the inmates are classified as being in the first stage of the disease, 12 in the second, and one in the final stage of the malady. During the official year there were four deaths, and three new cases were admitted from the surrounding districts. Dr. Smith was successful in inducing several of the less advanced cases to make a trial of chaulmoogra oil and creolin in treatment, and reports encouraging results. Whilst the Director-General of Public Health, Dr. Frederick Montizambert, was in British Columbia during the past summer he visited Darcy Island unofficially, where are confined five more lepers, all Chinese males. One of these is maintained by the province of British Columbia, and one each by the municipalities of Vancouver, Victoria, Kamloops, and Nanaime. This comprises the extent of leprosy in Canada at the present time.

Path logical Studies at William Head Quarantine Station.

During the past summer Mr. Charles H. Higgins, B.S., D.V.S, late official pathologist at William Head Quarantine Station, made an interesting study of the bacillus pestis bubonica. His morphological description of the plague bacillus is as follows. It is a short, thick, straight rod, with rounded ends. In length it varies from 0·7 to 1·2 millimetres and is half as broad. The bacilli sometimes occur in chains and have been observed in some cases to have a capsule. In fresh broth cultures they are often seen in chains resembling streptococci. In old cul ures they sometimes completely lose their elongated shape and appear as cocci. The germ takes the polar staining, leaving an unstained central portion. In unstained preparations and in the hanging drop this polar arrangement of the protoplasm is noticed. The form of the bacillus varies greatly according to the media upon which it is grown and also upon its age. Descriptions of cultural characteristics and observations on the inoculation disease in guinea-pigs, with symptoms and pathological lesions, also appear in the report.

Report of the Lunatic Asylums of the Province of Quebec.

The last official report on the asylum population shows

that there were 2981 of these unfortunates in the province, and the cost of maintenance is put down at $314,157·48 per annum, both figures showing an increase of those over the previous year. The report goes to show that the material and hygienic conditions of the three principal asylums of the province—Quebec, Verdun, and Longue Pointe—are in a very satisfactory state at the present time. The percentage of cures on the admissions of the past year has been somewhat less in each of the asylums of the province than it was last year. In 1898 Longue Pointe showed a percentage of 27·35 and in 1899 25·8; Quebec, 41·62 in 1898 and 31·75 in 1899; and Verdun, 43·63 in 1898 and 33 33 in 1899.

Canadian Association for the Prevention of Tuberculosis.

The conference summoned by His Excellency the Governor-General, Lord Minto, met in Ottawa on Feb. 14th and organised the above association, with the Governor-General as honorary president and Sir James Grant (Ottawa) president. Prominent medical men were present as delegates from each of the provinces. Amongst other questions discussed was that of Government aid to sanatoria, the tuberculin test as affecting the cattle-breeding business of the country, and the prevention of tuberculosis on the Indian reserves in Canada. The question of tuberculosis in immigrants was also taken up. Along these lines resolutions were adopted, and an organised effort may now be expected to be put forth in Canada for the prevention of tuberculosis in all its widespread ramifications. The association appointed a committee to confer with the Dominion Government as to the advisability of creating a department of public health.

News Items.

For the first time in the history of the Newfoundland sealing fleet physicians will accompany it. The fleet numbers about 6000 sailors and leaves St. John's on March 9th. Dr. Roddick, M.P., made the arrangements and the following are the names of the physicians from Toronto and vicinity who volunteered for the service: Dr. McWillie Martindale, Dr. W. F. Adams, Dr. McKinnon, and Dr. E. H. Stafford. No Montreal men were available.

While working in the laboratory of Professor Ruttan of McGill last week a first-year medical student from Prince Edward Island had the misfortune to have one of his eyes destroyed. In the test tube was some sulphuric acid and alcohol which frothed up in his face when presented to him for inspection by a neighbouring student.

The province of Ontario is on the verge of a small-pox epidemic. The disease is now located in some 15 centres and something like 100 cases have been reported, with two deaths. In the neighbourhood of Montreal there are six cases and the health authorities of that city are making strenuous efforts to keep the malady outside the city limits. The health officer of Montreal is prosecuting a vaccination crusade.

The Toronto Dental Society held its first annual clinic on Feb. 25th and 26th. Two features of the meeting were the "X Ray in Dentistry," by Dr. Price of Cleveland, U.S.A., and the "Surgical Treatment of Cleft Palates," by Dr. Truman W. Brophy of Chicago. Dr. Brophy described and demonstrated his operation at the Hospital for Sick Children before the leading dental and general surgeons of the city. He has operated on over 200 patients under five months of age with complete success.

Dr. Campbell Davidson, son of the Hon. Mr. Justice Davidson, has been appointed medical officer of the ss. *Montfort*, which left Liverpool on March 1st for Halifax to transport the Canadian contingent of General Baden Powell's police-force to South Africa.

March 6th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

An American Physician made a Major-General

DR. LEONARD WOOD, who commanded the Rough Riders in the Cuban campaign of the Spanish-American war, and who is at the present time Military Governor-General of Cuba, has been appointed by the President a major-general in the United States army. General Wood up to the time of the war with Spain had seen no active service as a soldier, although he had fought in the West in frontier warfare against the Indians. His promotion is said to have given rise to much heart burning in army circles, as it is considered unfair that a man who is virtually not a trained soldier should be thus put over the heads of men who have been in the army the greater part of their lives. Of course, such a procedure would be impossible in any other country than the United States, but notwithstanding its novel nature it may prove a wise step after all. General Wood has shown himself able and capable in whatever position he has been placed. He was an excellent physician, and probably had he elected to continue in practice he would have risen to a prominent rank in the profession. In the Cuban war, as colonel of the Rough Riders, he by no means disgraced himself, and as military governor of Cuba he has gained golden opinions on all sides. It has been mainly owing to his well-directed efforts that the large towns of that island are becoming metamorphosed from sinks of filth into fairly sanitary places of residence. It may be said, too, that the Cuban war, and to a still greater extent the South African war, have demonstrated the fact that to be a successful leader or soldier it is not always necessary to be a trained military man. In South Africa the colonials have fully held their own with the regular troops, and the same thing may be said as regards the volunteers in the Philippine Islands. It would, however, be somewhat curious if a man who was a physician until he was 40 should become the officer of highest rank in the United States army.

The Coming Exposition at Buffalo.

It is anticipated that the Pan-American Exposition, which will open at Buffalo on May 1st, will be a great success. A better situation for a large exhibition could hardly have been chosen. There are few more beautiful or picturesque cities in America than Buffalo both in itself and its surroundings. Niagara is within easy distance (about 20 miles) and can be reached by rail, electric cars, or by boat. Another strong point in favour of Buffalo is that it is only nine or 10 hours' ride by rail from New York and is connected with that city by no less than six lines, among these being the Grand Central and Lehigh Valley. Thus visitors from Europe will not be put to the inconvenience of a long and tiresome railway journey. The accommodation, both in the hotel and boarding-house lines, is probably better in Buffalo than in any town of its size in the United States. It is estimated that with the hotel buildings now in existence and those in course of construction the hotel accommodation of Buffalo is about 20,000. This, it is said, will be added to by 10,000 before May. The Statler Hotel, adjoining the Exposition grounds on the south, is now being built. It will be a temporary structure and will afford accommodation for 5000 people. The Esenwein, another temporary hotel near the Exposition site, is designed to accommodate 3500 guests. The Iroquois and Mansion House, which are permanent hotels in the business district of Buffalo, will accommodate 1500 each. The Lift House, also in the business portion, will house 1000, and the Genesee and Broezel 800 each. In addition to the hotels there are numerous boarding-houses, and many private houses will take in guests during the time that the Exposition is running. The exhibition buildings and grounds are well advanced towards completion and when May comes it is expected that all will be ready. A feature of the Exposition will be the portion devoted to science and medicine. Buffalo contains much of interest to medical men; it has an excellent medical university attached to the city hospital, besides another large and flourishing medical school and several hospitals, including one of the large State hospitals for the insane.

Sing-Sing Prison.

This institution for criminals of New York city, the buildings of which were erected in the year 1834, has long borne an evil reputation for unhealthiness. Latterly the prevalence of typhoid fever on a large scale among the prisoners has brought the question of the unhygienic state of Sing-Sing prominently before the public. The attention of the State Board of Health of New York has been called to the matter, and it seems, as a result of an investigation undertaken by the board, that the old prison is doomed to be either destroyed or put to some other use. Mr. Charles F. Wingate, consulting engineer to the State Board of Health, made an exhaustive examination of the sanitary conditions in Sing-Sing generally and of the sewage system in particular. The state of affairs that he discovered can only be characterised as appalling He found that the prison cells were but four feet above tide-water (Sing-Sing is situated on a bank of the Hudson about 30 miles from New York city) and that the sewage emptied into the Hudson at low tide backs up under the prison buildings. He also condemned the whole of the

plumbing system. Typhoid fever has been rife among the prisoners, there being more than 40 cases at one time, with two or three deaths, within the past three months. Acting upon the report of Mr. Wingate, the Prison Association has recommended in a special report to the Legislature that the prison buildings should be entirely removed and that a completely new penal establishment should be erected elsewhere. The report of the committee of the Prison Association states that the insanitary condition of Sing-Sing consisted in excessive dampness, the absence of sunlight, insufficient ventilation, and bad drainage.

The Pan-American Medical Congress: The Etiology of Yellow Fever.

At the Pan-American Medical Congress recently held in Havana the paper which received the most attention was that of Dr. Walter Reed, surgeon in the United States Army, on Yellow Fever and its Probable Propagation by Mosquitoes. The theory that the mosquito plays a leading part in the dissemination of yellow fever, although by no means new, has, it appears, received striking confirmation from the investigations of Dr. Reed and his colleagues, Dr. Carroll and Dr. Agromonte. When Dr. Reed first brought forward the proposition that the mosquito, as in malaria, acted as the intermediary host for the transfer of yellow fever from one patient to another, and that furthermore the bite of the mosquito was probably the only cause of infection, the announcement was treated with a certain amount of scepticism by many in the profession. However, later researches would seem to have clinched the argument in favour of this theory, and it is more than likely that experiments will result in conclusive proofs. The discovery that mosquitoes are chiefly instrumental in spreading both malaria and yellow fever would be of inestimable importance and would almost mark a new epoch in medicine.—Another paper of great value read at the Havana Congress was that by Dr. Walter Wyman, Surgeon-General United States Marine Hospital Service, upon Sanitation and Progress. Dr. Wyman takes the common-sense view that sanitation in many countries has not kept pace with scientific knowledge and declares that the problem of how to improve the sanitary condition of the poor quarters, to prevent the increase of foul, damp, dark, and overcrowded dwellings, and thus lessen the burden of the community without still further pauperising the people and attracting to the place other vagrants and criminals, is one of the most serious that confronts modern civilisation and municipal government. Dr. Wyman is of the opinion that a class of men to whom we should look for aid in advancing hygienic measures are the men of extreme wealth and believes that their attention should be directed to the vast amount of good to be done by the employment of their capital in backing up sanitary improvements "The methods by which such men may assist in public sanitation may not be so obvious or numerous as other methods of advancing the public welfare. Yet the influence of a man of great wealth could be distinctly felt in the advancement of sanitary legislation and in the perfection of sanitary administration. Moreover, the use of large capital in the improvement of the dwellings of the poor appears to be as noble and sensible a method of the employment of capital as can be found." The housing of the New York poor is as bad as anywhere in the world and is undoubtedly a potent cause of sickness. Dr. S. A. Knopf speaks on the situation as follows: "The present condition of the tenement houses in New York is so serious that the evils arising therefrom are a distinct menace to the welfare of the community. There are at present over 44,000 tenement houses in the old city of New York and new tenement houses are being erected at the rate of about 2000 a year. These are in many respects worse than the old buildings erected 30 years ago. They are badly constructed and so planned that many rooms depend for their light entirely upon long, narrow, dark air-shafts, which instead of giving light and air are merely stagnant wells emitting foul odours and diseases." The tendency of modern medicine is rather towards prevention than cure. The very first steps towards prevention must be to enable all to live under satisfactory health conditions. While the poor in most large cities are housed as at present it is impossible to prevent disease. The fact must also be borne in mind that an insanitary area in a town is a source of contagion and a menace to the rich as well as the poor. Thus it is false economy on the part of the wealthy to ignore the unfortunate position of the indigent; it would be wiser policy on their part to expend some of their money in making it possible for every individual to live under good sanitary conditions.

March 14th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Medical Society of Victoria: Presidential Address.

DR J. W. BARRETT, the retiring President of the Medical Society of Victoria, departed somewhat from the stereotyped form in his valedictory address. After referring to the continued progress of the society and the interest evinced in its proceedings he remarked on the absurdity of some of the customs of Victorians. Notwithstanding a beautiful, temperate, yet sunny climate, tubercle was too much in evidence. The people lived in villas, sleeping among the more numerous tubercle bacilli in the damper air near the ground and carefully excluded the sunlight by overhanging verandahs and window-hangings. Promiscuous spitting was also very common and should be prohibited by law. Another absurdity was the holiday custom. The maximum temperature in Victoria was reached about Jan. 20th. The State schools broke up about Dec. 20th and resumed about Jan. 20th. February was the most trying month, not because it was the hottest but because the resistance of the individual had been lowered by the previous heat. Why not have the holidays in February? Again, why make Easter fall on a variable date, sometimes in April rains, sometimes in March? Why not fix it for the second week in March and let people enjoy a respite after the heat? The bulk of Dr. Barrett's address dealt with the population problem. He showed that nowhere in the world was found the sudden and great drop in the birth-rate which had occurred in Australasia in the last 15 years. He attributed it to the extensive and deliberate adoption of means for restricting families, and he considered that the so-called "emancipation of woman" was largely responsible for this state of affairs. Practically all careers had now been thrown open to women, while previously marriage was the only one; and ambitious women preferred the business to the old-fashioned career. They might even marry and pursue their profession or business by avoiding maternity. But such a choice on a large scale meant that women were doing that which men could do and leaving undone that which men could not do. No woman now, in bearing a child, thought of the State or of doing it a service, like the old Roman matrons. Medical men should understand the question in all its many-sided aspects and be in a position to give advice, and that advice might be that it was not possible to cheat the Almighty without paying a very heavy penalty—personally and racially. The personal penalty was an old age cramped mentally and morally with attendant neuroses, and in which the individual could not look back to a life fully spent and in which he or she had graduated in all the faculties of human relationships.

Typhoid Fever in Sydney.

The medical adviser to the Sydney Water and Sewerage Board, Mr. T. Mailler Kendall, has presented a report dealing with the incidence of typhoid fever in Sydney during last year. Altogether, he stated, the epidemic had been very severe and the mortality great. The greatest incidence occurred during the first quarter of the year, especially during March, and the least in the third quarter. The largest number of cases—241, or 25 5 per 10,000 of population—occurred in the city itself. Mr. Kendall attributed the prevalence of the disease to deficient sanitary control, both as regards drainage and the removal of refuse.

Sanatorium for Zymotic Diseases at Melbourne.

The new hospital or sanatorium for zymotic disease at Melbourne has just been completed. It is situated at Wode island on the river Yarra, and was commenced during the plague outbreak. The buildings are of the most modern type. Two wards are provided, each with nine beds, isolated from each other and separated also from the quarters of the staff and administrative offices. The floors are of Trinidad asphalte and the whole of the interior of the wards has been so constructed as to admit of thorough cleansing and disinfection. There is also ample provision in the way of disinfecting appliances, bathrooms, and lavatories, and a pathological and bacteriological laboratory has been added. The drainage

will pass into a large tank, from which it will be pumped and thoroughly disinfected before being discharged into the river.

Inebriates Act of New South Wales.

Last session Mr. Creed, M.L.C., succeeded, after repeated attempts, in placing upon the statute-book of New South Wales an Inebriates Act, providing for the establishment of suitable homes for inebriates under proper supervision. Quite a volume of regulations under the Act has just been gazetted. These regulations provide that applications for licences under the Act must be endorsed by any two duly qualified medical practitioners, clergymen, or justices of the peace who have known the applicant intimately for not less than two years. Another provision is that no licence shall be issued for any persons to establish an institution for inebriates until its locality has been declared suitable and the buildings, grounds, and appliances necessary for efficiently carrying on such an institution shall have been inspected and approved by a Government visiting committee and the inspector-general of insane and declared by them in writing to the principal under-secretary to be fully suitable and sufficient for such a purpose. The 42nd regulation is as follows and has been adversely criticised as possibly giving opportunity for maladministration:—

> In the event of an inquest being held upon any patient who shall have died at a licensed institution the proceedings thereof shall not be published, nor shall any information with regard to them be furnished to the press for publication by any person unless, in the opinion of the coroner or the patient's next friend or executor, it is necessary for such information to be made public in the interests of justice and then it shall be supplied by the coroner only in any form and to any person he may think fit.

Newcastle Hospital, New South Wales.

The annual report of the Newcastle Hospital showed that satisfactory progress was being made with the erection of the additional buildings forming a nurses' home and operating wing. In the out-patient department the number of attendances had increased from 3718 to 4214. The committee think that "there is greater imposition practised by out-patients than can be detected by the present means of inquiry." The income for the past year was £3808, and the expenditure was £3039. The average cost per in-patient per annum was £54 17*s.* 3*d.*; the average death-rate was 8·19.

Illegal Use of Medical Titles.

At Broken Hill, New South Wales, recently, Mahomed Fandledeen, a native of India, was charged under the new Medical Act (New South Wales) with illegally using the title of "Doctor," and was fined £50, with costs. Two other cases against a man who styled himself "Professor" and a "Chinese doctor," were dismissed. At Collingwood, R. V. Danne was charged with representing himself to be a doctor of medicine while not registered in Victoria. The defendant said that he was prepared to plead guilty and to consent to a fine of £5 and £5 5*s.* costs. The prosecution agreed and a verdict was given accordingly without calling evidence. The defendant gave a remarkable death-certificate recently in a case where an inquest was held—viz., that the deceased was "still-born," and under the heading, "Duration of life," put "a few hours."

Death of Dr. L. E. F. Neill.

The somewhat sudden death of Dr. Leo E. F. Neill from pneumonia came as a great shock to the profession in Sydney, of which he was a most gifted member. He had a brilliant career at the Sydney University, where he graduated in arts before studying medicine and carried off several scholarships and gold medals, chiefly in classics. In his medical course he was equally successful, graduating with honours in 1890. After two years' residentship at the Prince Alfred Hospital he visited America and made himself familiar with the methods obtaining in the leading hospitals there. He then settled in practice and soon earned an enviable reputation for so young a man. He was assistant surgeon at the Prince Alfred Hospital and surgical tutor and assistant surgeon at the Women's Hospital. He was also a great footballer and played in leading matches against the other colonies.

Feb. 8th.

THE annual distribution of prizes to the Volunteer Medical Staff Corps (London Companies) will take place this evening (Saturday) at 8 P.M. Mrs. J. Edward Squire will distribute the prizes.

Obituary.

SIR EDWIN SAUNDERS, F.R.C.S. ENG., F.G.S.

THE death took place at his residence, Fairlawn, Wimbledon Common, on March 15th, of Sir Edwin Saunders at the advanced age of 87 years. It was at his house that the first steps were taken in 1857 to unite together those practising dental surgery by the formation of the Odontological Society. He was the first treasurer of the society and subsequently filled the office of councillor, vice president, and president in 1864 and 1879. He was until quite recently one of the trustees and on his resigning that office he was unanimously elected an honorary member. Sir Edwin Saunders was amongst the earliest to memorialise the Royal College of Surgeons of England with a view to obtaining recognition by examination and diploma for dental surgeons. He, with others, in 1857 established the Dental Hospital of London and Medical School in Soho-square and retained for many years a keen interest in that institution. It was owing to his self-sacrifice and liberality that the building in Leicester-square was equipped and handed over free from debt. He took an active part in the management until it was decided to build an entirely new hospital. With this movement he did not agree and accordingly dissociated himself with the hospital. At the meeting of the International Congress in London in 1886 he occupied the chair of the dental section. He took an active part in the British Dental Association in the early years of its existence and at the meeting in 1886 was the president. For over 50 years Sir Edwin Saunders held the appointment of dental surgeon to the late Queen, and in 1883 received the honour of knighthood. Sir Edwin Saunders was married to Marion, daughter of Mr. E. Burgess, and on the occasion of their golden wedding, as a fitting memorial to his long professional career, his friends presented him with an illuminated address and Lady Saunders with a diamond brooch.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a congregation on March 14th the following were admitted to medical and surgical degrees.

M.D.—J. Gutch, M.A., and W. M. Sing, M.A., Christ's.
M.S.—R. H. Urwick, M.A., Trinity; A. H. Style, B.A., Emmanuel.
M.B. and B.C.—E. H. Coleman, B.A., St. John's.

—Applications for the John Lucas Walker Studentship in Pathology, value £200 for three years, are to be sent to Professor Woodhead by April 16th. Candidates who are not members of the University are eligible.—Several important modifications in the regulations for the M.B. degree are proposed by the Medical Board in a report dated March 11th which has just been published.—Tenders for the erection of the new Botany Schools, amounting to nearly £23,000, have been accepted by the Senate. The building operations will begin forthwith.

NAVAL AND MILITARY EXHIBITION.—With the approval and under the patronage of Earl Roberts, the Commander-in-Chief of the army, the directors of the Crystal Palace Company will commemorate the jubilee anniversary of the Great Exhibition of 1851 by holding in the building which was originally erected by Sir Joseph Paxton in Hyde Park and subsequently transferred to Sydenham a Naval and Military Exhibition in the coming summer. Here will be illustrated the important innovations of the past 50 years in all branches of naval and military warfare. There will also be a series of special displays, comprising tournaments, historical tableaux, and miniature battles. The council of advice is composed of about 300 officers of both services. While affording instruction and amusement to the general public the exhibition should prove a means of helping the families of soldiers dependent upon the various naval and military charitable funds. These institutions have availed themselves of the gift by the Crystal Palace Company of 50,000 guinea season tickets, the entire proceeds of the sale of which will be credited to the particular societies disposing

of them. The tickets are now ready for issue and will be available until April 1st of next year. The proceeds of special concerts and other entertainments will also be devoted to these charities. The date of opening has been fixed for May 2nd and the exhibition will remain open for a period of five months.

AN IN MEMORIAM GIFT.—Miss H. Beatrice Kekwick of Bramcote Lodge, Scarborough, has given £1000 to the Scarborough Hospital and Dispensary, in memory of her father, the late Mr. John Kekwick of Cairnforth, Rotherham.

HEALTH OF BATH RURAL DISTRICT.—At the meeting of the Bath Rural District Council held on March 9th the medical officer of health (Mr. C. Harper) presented his annual report for 1900. This showed that the population of the district was estimated at 28 285, the area being 27,266 acres. The deaths in the 19 parishes were equal to a rate of 11·84 per 1000. The birth-rate corresponded to a rate of 24·35 per 1000.

ROYAL STATISTICAL SOCIETY.—A meeting of this society was held at its rooms, 9, Adelphi-terrace, Strand, W.C., on March 19th, the President, Lord Avebury, F.R.S., being in the chair. A paper, being the essay which was successful in the Howard medal competition of the session 1899–1900, was read by Dr. J. F. J. Sykes on "The Results of State, Municipal, and Organised Private Enterprise on the Housing of the Working-classes in London and other Large Cities in the United Kingdom."

APPOINTMENT OF A MEDICAL OFFICER OF HEALTH.—At the meeting of the Axminster Rural District Council held on March 14th it was reported that there were five applicants for the post of medical officer of health. Each candidate had been required to fix his own remuneration and the gentleman who mentioned the lowest was elected. Mr. G. Evans of Seaton, who had been medical officer of health for 13 years, complained that he had not received any notice of the termination of his engagement, but the explanation was given that the appointment, being a yearly one, expired at the end of the year.

MEDICAL FEES.—At the Truro County Court, held on March 15th, Mr. A. L. Salmon, M.R.C.S. Eng., L.S.A., sued a patient for £11 for professional attendance and medicine. Mr. Salmon had attended defendant from September, 1900, to January, 1901, and had called in Dr. R. H. Clay of Plymouth in consultation. The solicitor for the defence said that he would submit to judgment except in regard to two items—viz., 10*s.* for medicine on Jan. 6th, and 2*s.* for a visit on Jan. 22nd. The defendant also contended that on three different occasions the medicines were inaccurately dispensed. Judge Granger said that the evidence did not satisfy him that the wrong medicine was sent, and he did not think that a court had ever been asked to take away the character of a professional man on such flimsy evidence. He gave judgment for £11 and costs.

ROYAL INFIRMARY, HULL. In proposing the adoption of the 118th annual report of the committee of the Hull Royal Infirmary at a meeting held in the infirmary buildings on March 14th, Sir James Reckitt, Bart., the chairman, said that for some years past hundreds of patients had been turned away from the institution who ought to have been admitted for treatment if there had been room. In one week 25 patients were sent out of the institution insufficiently cured, but there were other cases of more importance waiting, and they would probably have died if room had not been made for them. It was therefore inevitable that the institution should be increased as soon as possible. A meeting would soon be called for the purpose of making the infirmary a rallying point for some memorial to the life of Queen Victoria the Good. Sir Robert M. Craven seconded the adoption of the report and said that at the present time the hospital was totally inadequate for its purposes. He referred to the difficulty in getting surgeons and said that he did not think that they would succeed unless they increased their salaries. He hoped that the institution would never have a female doctor. He suggested that the whole of the staff should be on the standing committee. He also remarked that what used to be a down-trodden profession was asserting itself and, like the skilled workman, the surgeon demanded payment for his skill and they would have to pay it. The report was adopted.

UNIVERSITY COLLEGE OF SOUTH WALES.—Mr. Alfred Thomas, M.P., has been elected President of the University College of South Wales in succession to Lord Tredegar who has held the office during the last five years and who is debarred by statute from re-election.

BRISTOL UNIVERSITY COLLEGE COLSTON SOCIETY.—At a committee meeting held on March 7th it was stated that during 1900 the subscriptions of this society amounted to £405. In the present year the amount contributed is £422. The committee resolved to grant £400 to University College.

EXETER LUNATIC ASYLUM.—At the meeting of the Exeter City Council held on March 13th it was stated that the cost of maintenance for the Exeter patients in the asylum had been reduced from 12*s.* 10*d.* to 10*s.* 6*d* weekly, and thereby £900 had been saved, and that a corresponding reduction would be made in the poor-rate.

APPOINTMENT OF A COLLIERY SURGEON.—Dr. Llewelyn Roberts of Newtown, Montgomeryshire, has been elected surgeon to the Great Western Colliery, Pontypridd, in succession to the late Mr. J. L. Leckie who held the position for many years. The number of men employed in the colliery is over 2000 and they contribute 3*d.* in the pound of their earnings towards the salary of the surgeon. There were 35 applications for the appointment. A committee of the men selected two of the candidates and on March 11th and 12th a general ballot of all the colliers employed took place with the result indicated.

LEEDS GENERAL INFIRMARY.—The report for the past year shows a deficiency of over £8000. The cost of each bed occupied was £68 2*s.* 0¾*d.*, as against £64 12*s.* 2*d.* in 1899. The average cost of the in patients had been increased partly by their having each stayed one day longer, but the chief reason had been the increase in the cost of living. The coal bill showed more than £700 extra and drugs and surgical dressings £522 extra. The number of out-patients had also increased. The alterations of the old casualty department and the building of the new sitting- and bedrooms for the resident staff had cost £4172. Mr. Charles Lupton made an earnest appeal for funds.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, MARCH 14TH.

Civil Surgeons and Nursing Sisters in South Africa.

Sir ANDREW AGNEW asked the Financial Secretary to the War Office whether the civil surgeons and nursing sisters employed in tending the sick and wounded in South Africa would be entitled to the same war gratuity as those connected with the army.—Lord STANLEY: Civil surgeons, civil veterinary surgeons, and nursing sisters are employed under a definite contract as to pay and are not entitled to any war gratuity.

Medical Attendance for Soldiers' Families.

Mr. ARCHDALE asked the Financial Secretary to the War Office whether the wives and families of soldiers, embodied militia, or reservists serving with their corps, were only entitled to free medical attendance when residing within reach of an officer of army medical corps or of a civil practitioner engaged at military contract rates; and, if so, would he say who was to pay for medical attendance for those who lived outside that distance and were too poor to pay for themselves.—Lord STANLEY: It has been explained to the House before that it is not possible to provide medical attendance for those residing at a distance from military headquarters.

Enteric Fever Infection.

Sir WALTER FOSTER asked the Financial Secretary to the War Office whether he was aware that clothes of men dying in South Africa from enteric fever were returned to this country in a dirty state; and whether, in consequence of the danger of infection now increased by the prevalence of plague in Cape Colony, he would order that the kits of soldiers dying from disease should be thoroughly disinfected before being returned to this country or destroyed and proper compensation made to their relatives.—Lord STANLEY: No clothing of men dying in South Africa is returned to the Clothing Department at home, and nothing is known of any having been sent home privately. In accordance with the Regimental Debts Act the personal effects, except special articles left by will belonging to a soldier dying on active service, are sold by auction on the spot. Special cautionary instructions as to the spread of infection have been sent out.

FRIDAY, MARCH 15TH.

The Vaccination Question.

Mr. LEVY asked the President of the Local Government Board whether, having regard to the declaration of his predecessor in that House on July 20th, 1898, that the administration of a compulsory vaccination law would be neither necessary nor desirable, and the tacit

promise of the same Minister on the same date that the Local Government Board would not do anything to interfere with the relations between vaccination officers and the guardians who employed and paid them, he would withdraw the circular issued by the Local Government Board.—Mr. CHAPLIN: As the question of the hon. Member contains two distinct statements affecting myself, perhaps before it is answered I may be allowed to make a very brief personal explanation. As to the first statement the hon. Member, who is new to the House, is probably not aware that I have repeatedly explained that it referred solely to the concession which was made by the Government on the previous evening. With regard to the second statement I have repeatedly shown that the statement and the inferences which are drawn from it are both of them equally erroneous.—Mr. WALTER LONG: My right hon. friend has dealt with the allegations in the question and it only remains for me to say that I decline to withdraw the circular.

Hospital Provision in the Scottish Highlands.

Mr. WEIR asked the Lord Advocate whether in view of the difficulty experienced in securing suitable hospital accommodation in the poorer districts of the Highlands and Islands of Scotland he would consider the expediency of introducing legislation such as would provide for the establishment and maintenance of hospitals in congested areas.—The LORD ADVOCATE: The Secretary for Scotland would not be disinclined should a favourable opportunity present itself to amend the Congested Districts (Scotland) Act, 1897, in one or two respects and in this event he will consider whether the point mentioned in the hon. Member's question can be provided for.

Civil Surgeons in the Army.

Mr. RANDLES asked the Secretary of State for War, having regard to the fact that the civilian veterinary surgeons at home stations during the war emergency were drawing pay at the rate of £250 per annum and allowances, which brought their pay to over £30 per month, and received a gratuity of two months' pay after 12 months' employment and an extra month's salary for each additional six months' service, (1) could he state what increase of salary and gratuity the Government proposed to pay those civilian medical practitioners who had been engaged at home stations for the last 12 months and upwards at a salary of only £270 per annum; and (2) could he explain why the gratuity of £100 for the first year of service with troops at home and £50 for the succeeding years awarded to civilian medical practitioners holding commissions as medical officers to volunteer corps and militia regiments had been refused to the civilian medical practitioners who offered their services during the war, seeing that the rate of pay to the civil surgeons proceeding to South Africa had been increased from one guinea to one and a half guineas per diem with same allowances and gratuity.—Lord STANLEY, replying on behalf of the Secretary of State, said: In regard to the first paragraph of the question the civilian surgeons and veterinary surgeons employed at home stations are paid at army rates and there is no intention of making any alteration in their pay. In regard to the second paragraph medical officers belonging to the militia and volunteers are treated as officers under army rules, while private medical practitioners are treated according to the terms on which they engage.

Pneumonia on H.M.S. "Britannia."

Mr. EUGENE WASON asked the Civil Lord of the Admiralty whether he was aware that an outbreak of influenza followed by pneumonia occurred on board H.M.S. *St. Vincent* at Portsmouth last year owing to the contamination of the site of her moorings, and that since the moorings had been dredged there had not been any similar outbreak on board the *St. Vincent*; could he state how long she was away from her moorings; and would he cause the *Britannia* to be removed to other moorings, and not to be again moored in the same position until the site had been thoroughly dredged and the accumulation of filth for years removed.—Mr. PRETYMAN: There was an outbreak of influenza accompanied by lung and other affections on board the *St. Vincent* in 1899. The ship was specially inspected at the time by the Medical Director-General; the whole question of her sanitary condition was inquired into and the ship was thoroughly overhauled. There was no evidence that the outbreak was due to contamination at the site of the moorings, but the moorings were in fact dredged because it was found that the ship touched the bottom at low water. There has been no outbreak of any importance since the date named. The *St. Vincent* left her moorings on July 6th, 1900, and returned to them on Oct. 29th. A committee, composed of Sir Henry Norbury (Medical Director-General), Professor Caulfield, Inspector-General Fisher, and Fleet Surgeon May, has been engaged during the last two days in examining H.M.S. *Britannia* and making inquiry into all the circumstances likely to effect the health of the cadets. The committee has now terminated its inquiry and its report is expected immediately. Until that report is received I should prefer to postpone answering the last part of the hon. Member's question, but I may say there is no reason to believe that there is any accumulation of filth under the *Britannia*.

TUESDAY, MARCH 19TH.

Medical Provision at Shoeburyness.

Mr. BARTLEY asked the Secretary of State for War whether he was aware that no provision existed in cases of illness among officers at Shoeburyness, there being no hospital, no arrangement for nurses, and not even a single member of the Army Medical Corps; whether he was aware that this week a young officer who had served in South Africa was taken ill with double pleurisy which resulted in double pneumonia; that he was left in his own quarters where he died, and had it not been for his parents would have had no nursing or medical appliances; that recently, in consequence of an officer developing scarlet fever, the whole batch of officers in that officer's quarters had to be put under tents; and whether immediate steps would be taken to provide a suitable hospital, nurses, and appliances at Shoeburyness for officers when taken ill there.—Mr. BRODRICK. It has not been found possible to provide accommodation for hospital wards for officers at home stations except at Netley and Woolwich and in special cases at Aldershot. Officers, except when suffering from wounds or illness from active service, are only admitted to these hospitals on the recommendation of a medical board. At Shoeburyness there are two medical officers. For the case of pneumonia one day and one night nurse were engaged from the beginning by the medical officer and remained to the last. As regards the case of scarlet fever some young officers residing in the same corridor were very properly removed; it does not appear a hardship that they were placed under canvas.—Mr. BARTLEY: Will the right hon. gentleman undertake that some provision will be made for these severe cases that occur sometimes?—Mr. BRODRICK: This officer was duly attended by the proper medical officer and had a day nurse and a night nurse from beginning to end. I do not in the least admit that in an officer's quarters proper attention cannot be given.

The South African Hospital Commission.

Mr. DALZIEL asked the First Lord of the Treasury whether he could state the amount of salary paid respectively to members of the South African Hospital Commission in addition to the amount allowed for personal expenses.—Mr. BALFOUR replied that a sum of £1250 was paid to each member of the Commission except the chairman.

Mr. DALZIEL asked whether he was to understand that the chairman was not paid.—Mr. BALFOUR replied that the chairman was not paid.

WEDNESDAY, MARCH 20TH.

The South African Hospitals Commission and its Report.

In the early hours of the morning—indeed, shortly after midnight—there was a long debate on the South African Hospitals Commission and its report. The debate arose upon a supplementary vote in Committee of Supply for the expenses of temporary commissions. Mr. BURDETT-COUTTS opened the debate. He laid down these propositions: that the inquiry of the Commission had been partial and imperfect, that its conclusions were lame and impotent, and that its recommendations for reform were framed altogether on wrong lines. The subject, he said had been investigated in a manner which had thrown a cloak over the true extent and nature of the defects of the Army Medical Department and had concealed the causes of those defects and the responsibility for them. While they had condemned a general for inaction in the field they were content with an inquiry which did not point out the connexion between cause and effect and which failed to push home the responsibility in any quarter. The hon. Member then went on to blame the Commission for not securing powers to take evidence on oath, for accepting the guidance in all its movements of the organisation of the Army Medical Department, and for refusing certain evidence offered it. He condemned the examination of patients in batches while they were still in hospital under the care of officers of the department. In South Africa, he said, nine-tenths of the patients were so examined. In his original complaint he had made a great point of the bad feeding of the convoys by train, but while this was so out of 154 patients examined only seven were asked any questions as to their feeding while in train convoys and four of these said what he had always maintained—that they hardly ever had anything but bully beef and biscuits. As for the reform of the medical provision of the army, he appealed to the Secretary of State to go outside this report in framing his scheme. If there was an era in which not so much new legislation was necessary as that we should set our house in order, and if for that purpose a full, relentless, and searching examination of its defects were necessary, then the worst model they could take for such an investigation and the weakest and rottenest basis of reform was this farce of an inquiry for which Parliament was now asked to pay.—Mr. DALZIEL quoted from the report and argued that the Army Medical Department had proved inadequate for the work of the campaign.—Sir WALTER FOSTER submitted that the report was tantamount to an admission of the case made out before the appointment of the Commission. If they analysed the figures in the report and examined the other material they would find a very grave condemnation of the medical arrangements. The only recommendation of the Commission was that there should be appointed a Committee to do the work the Commission had not done. The object of the Commission was not to prepare a defence of the Army Medical Department but to inquire into the care and treatment of sick and wounded. The Royal Army Medical Corps had not been attacked in this House. Members had fully recognised that the Corps had done as well as it could do in the circumstances, and probably it had done as well as any other department of the army, but the Royal Army Medical Corps was unequal to the demands made upon it. Civil surgeons had to be relied upon largely, and the number of these civil surgeons employed gave some measure of the deficiency which would have to be made good in the Royal Army Medical Corps.—Mr. BRODRICK said that the question before the House was simply the question of how the Commission had performed its duties. There was no doubt that the Member for Westminster (Mr. Burdett-Coutts) had made a most vehement attack upon the character of the inquiry and the principles brought to bear upon it by the Commissioners. In the few words which he (Mr. Brodrick) proposed to say he would like to ask the House as a matter of common sense, upon what grounds were these sinister motives imputed to this Commission. Supposing, as the hon. Member had suggested, there had been a determination to shield the Royal Army Medical Corps, to burke the intended inquiry and to report something which might be favourable to the authorities, what could be the motive of these independent gentlemen, not one of whom had anything whatever, so far as he knew, to gain from the Government in the matter, who were absolutely independent of all Government influence, and who were themselves gentlemen of high character—what could be the motive which would induce them to act in the manner which the hon. Member believed they had acted throughout this inquiry? He held no brief for the Commission. They were a body of high-minded gentlemen who had given an immense amount of hard work without any remuneration of any sort or kind. They had travelled many thousands of miles, and they had simply taken up this business for a public purpose and with the honest intention of reporting on the state of things they found. If their report was not altogether satisfactory to his hon. friend and other Members of the House he could only say that so far as he was concerned he was not bound by the four corners of the report. In the nature of things it could not be an exhaustive report. It was not an accurate statement to say that the Commission had recommended the appointment of a Committee to do the work which they themselves were appointed to do. The Commissioners were appointed to consider and report upon the care and treatment of the sick and wounded in the campaign. They might or might not have carried out that charge to the satisfaction of hon. Members, but he thought they were fully justified in their recommendation that a Committee should be appointed to inquire and report upon the steps necessary to put the Royal Army Medical Corps upon a proper footing. He thought that the Members who had spoken had pressed the matter against the Commission in

some respects a great deal too far. But at this hour he was not going to weary the House by trying to discuss the points in detail. As a matter of fact, he had been so busy with other work recently that he had not been able to go into the subject of this report very deeply. He did not wish to make any gulf between himself and those Members who did not think this report the best medium for the commencement of a reform of the army medical service. He would remind the House, however, that the shortage of the Royal Army Medical Corps lay as much at the door of Parliament as of any other body. He did not think they ought, looking at this matter quite impartially, to cast an unmerited slur upon men who had tried to do their duty properly according to their light. Nor did he think it ought to be supposed for a moment that a Commission appointed to discuss the care and treatment of the sick and wounded during the campaign could cover the whole ground or be their only guide as regarded the future of the army medical service. He would also ask the House to believe that he was not looking in the reorganisation of this service for salvation either to this Commission alone or to the *personnel* of the Royal Army Medical Corps alone. He was perfectly aware that the past of the Royal Army Medical Corps had been unsatisfactory in two respects. First of all they had had far too small a choice of men to bring into the corps, and until they could remedy that defect they should not get an efficient service, and in the second place they had had far too little elasticity in the service. He assured the House that he approached the subject with a perfectly open mind. He did not feel at all certain that they could build altogether upon the existing foundation They would not limit themselves to any official sources for inspiration in the reorganisation of the corps and he was not in the least without hope that before very long the steps that they were about to take would enable them to bring before the House a scheme which would give them, what they were determined to have, a really effective Royal Army Medical Corps.—Several Irish Nationalist Members continued the debate, among the number Dr. THOMPSON, who bore testimony to the devotion to duty and hard work of the members of the Royal Army Medical Corps and insisted that if there were any blame in the matter it was to be attributed, not to the members of the corps, but to the system under which they had to work.

ROYAL COMMISSION ON ARSENICAL POISONING.

WEDNESDAY, MARCH 13TH.

THE Royal Commission on Arsenical Poisoning met on March 13th, in the Westminster Palace Hotel, London, and proceeded with the examination of witnesses. Lord KELVIN occupied the chair and the other Commissioners present were Sir William S. Church, Sir William Hart Dyke, M.P., Professor Thorpe, and Dr. B. A. Whitelegge, with Dr. G. S. Buchanan, secretary.

Evidence of Dr. George Reid.

Dr. GEORGE REID, medical officer of health of the county of Stafford, was the first witness examined, and in reply to the Chairman he said that the administrative county of Stafford was divided into 57 sanitary districts, of which 38 with a population of 677,968 were urban districts, and 19 with a population of 229,148 were rural districts. There were 50 medical officers of health in the administrative county, seven of whom acted for joint districts formed in each case by the union of two authorities. As it seemed desirable, so far as clinical evidence was concerned, to cover the geographical county, he appealed to medical officers of health of the county boroughs as well as to those of districts within the administrative county for information and in every case he obtained very full information. As time was of importance, it was not found practicable to communicate direct with every medical practitioner in the county, but he suggested that this should be done locally by the different medical officers of health, and in most cases he believed his suggestion was acted upon. He thought it desirable, however, to make an exception in the case of members of medical staffs of the general hospitals in the county, of which there were 14. In this way he obtained information about a large number of cases—altogether 667 from the county. Samples of beer were taken and as the results of the analyses were reported the clerk of the county council communicated with the implicated beer-sellers, intimating that they would incur a serious responsibility unless they discontinued the sale of arsenical beer, and witness visited the implicated breweries in order to ascertain what steps the brewers proposed to take to put a stop to the sale of the arsenical beer and to obtain what information he could as to the source of the arsenic. In the case of two breweries, one in Manchester and the other in Liverpool, he communicated with the medical officer of health of those cities, but he included among his visits four breweries in Shropshire adjoining the Staffordshire boundary. Without exception the brewers afforded him every information, and each brewer was either actually engaged in calling in the contaminated beer or had already done so. He believed this was thoroughly done in most cases, either voluntarily or in consequence of his visit, though in many cases large quantities of arsenical beer were retained in the hope of obtaining a return of the duty. This involved some amount of risk, and in one instance at least which led to a prosecution the beer after being interdicted by the brewer was sold by the tenant of a tied public-house. He thought it was unfortunate that the Inland Revenue Department did not at once intimate whether or not the duty paid would be refunded. Altogether, 140 samples of beer were analysed in the first stage of the inquiry, and of these 15 were found to be decidedly arsenical and seven very slightly so. 11 samples of glucose and brewing and other sugars were analysed, and two of the first-mentioned, both obtained from the same manufacturer (Bostock), were found to be arsenical. The amount of arsenious oxide in the contaminated beers varied from a trace (well under one-twentieth of a grain per gallon) to just over half a grain per gallon. The 140 samples of beers analysed were collected in 28 different sanitary districts from 140 distinct sources, and they represented the beers of 90 brewers, including 26 which were home brewed. He might mention that only in one instance did they fail to trace the contamination of the beer to the use of Bostock's glucose. The exception was a brewery in Shropshire and in that case they did not succeed in tracing the source of the contamination, the brewer assuring witness that he had not used Bostock's glucose within the last 12 months. Of the 667 cases tabulated by witness 290 occurred in Lichfield (rural), 91 in Lichfield (urban), 88 in Darlaston (urban), 69 in Stone (urban), 31 in Brownhills (urban), 14 in Cannock (urban), 13 in Tipton (urban), five in the County Borough of Hanley, four in the County Borough of Walsall, and four in Stafford (urban). He had no official knowledge of any fatal cases, but from what he could ascertain one, if not two, deaths might have occurred. One remarkable and, from a clinical point of view, instructive fact had been demonstrated by the inquiry in Staffordshire—namely, that whereas at least 67 per cent. of the cases were attributable to one implicated brewery, another and larger implicated brewery, supplying a much larger population, did not give rise to recognisable cases of illness calling for medical treatment. In the first case the quantity of arsenic per gallon of beer was found to be a little over half a grain, while in the latter case only one-tenth of a grain was found. In both cases it so happened that the quantity of glucose used to malt was 20 per cent. and the amount per gallon 5·1 and 5·6 ounces respectively; but whereas in the former case one glucose only (Bostock's) was used, in the latter the brewer used a mixture of equal parts of three different glucoses, only one of which was Bostock's. Thus, while the actual quantity of glucose used was very much the same in both cases, the relative proportion of arsenical glucose per gallon of beer was 5·1 and 1·8 ounces respectively, a proportion which was consistent with the quantity of arsenic found in the two beers. As it would appear, then, that thousands of persons for an unknown period had been drinking beer containing one-tenth of a grain of arsenic per gallon without suffering any effects sufficient to call for medical attendance, the question arose, Was this the first occasion on which arsenical beer had been brewed, and might not some illness have previously occurred which, in view of what we now know, might have been attributable to arsenical poisoning? After an interval of about four weeks—about the end of the third week in January—a systematic collection of samples was again undertaken, attention being specially directed to the public-houses supplied by the previously implicated brewers. As the outcome of this second collection 43 samples of beer, 10 of confectionery, and five of golden syrup were analysed, and all were found to be free from arsenic. Circulars had also been addressed to most of the medical practitioners who had previously reported cases, and from the replies received it would appear that 60 of the original patients were still suffering from the symptoms. A few fresh cases were also reported by two medical practitioners, but from subsequent inquiry he was by no means satisfied that the cases were of recent origin. He doubted whether one-fiftieth of a grain of arsenic taken every day in food would produce symptoms, but in his opinion it would be very undesirable to have one-fiftieth of a grain in a gallon of beer. Questioned on the subject of future preventive measures Dr. Reid made the following statement, viz.:—In the first place, as the use of wholesome glucose in brewing is not injurious from a health point of view, and if it be a fact that, in this country at any rate, its use facilitates the brewing of light beers, it would seem to be a mistake either to prevent its being used or to impose any conditions which might, in view of the ignorance of the public regarding the question, lead to beers of a heavier quality being consumed. At the same time, effective steps should be taken to guard against any such unfortunate calamity as has recently been experienced, and I would suggest:—

(*a*) That no glucose or invert sugar shall be manufactured with sulphuric acid unless the acid has been made from sulphur and is arsenic free, and that the brewer shall obtain a guarantee to that effect from the sugar manufacturer with each consignment.

(*b*) That the Inland Revenue Department shall be called upon to exercise control over the quality of brewing materials from a health point of view by its being made part of the routine duty of excise officers to see that the above guarantee has been obtained and to periodically collect samples of such materials for analysis by the Somerset House officials.

(*c*) That such precautionary measures, combined with the exercise of the powers already possessed by sanitary authorities under the Food and Drugs Act, combined with additional powers enabling such authorities to seize and destroy contaminated beer, should suffice to prevent the possibility of a similar occurrence in the future and afford a satisfactory guarantee to the public that their interests were being looked after.

By Sir WILLIAM S. CHURCH: He understood that sulphuric acid made from sulphur was not likely to contain arsenic and that was the reason for his first suggestion.

By Professor THORPE: He thought that the public were entitled to have an assurance that every precaution would be taken in the future and they would not have that assurance if they realised that a substance was being used which, previously to its use, required a process of purification. His opinion in this connexion would not be altered if it were shown that by far the larger number of glucoses and inverts were made from pyrites, purified from arsenic and that these substances were free from arsenic.

Dr. Thomas Stevenson Examined.

Dr. THOMAS STEVENSON, Vice-President of the Chemical Society and of the Institute of Chemistry, lecturer on forensic medicine at Guy's Hospital and scientific analyst to the Home Office, was next examined. In the course of his evidence he stated that he went to Manchester early in the epidemic. On Nov. 28th he inspected the dead bodies of two women in the Crumpsall mortuary, saw and examined a considerable number of men and women in the Crumpsall Infirmary, and arrived at the conclusion that the patients were suffering from chronic arsenical poisoning and that probably the two women who were there dead had died from arsenical poisoning. He obtained viscera from the bodies of the two women referred to and from three other women and submitted them to analysis for arsenic and other mineral poisons. He ascertained that the five women had all been drinkers and four of them had drunk beer largely. The histories of the two women, their symptoms, and the post-mortem appearances externally, such as pigmentation rashes and the excessive accumulation of epithelial scales, all pointed to arsenic. In four of the five bodies arsenic was found in the viscera; in one

case only in notable quantity; in three cases in minimal amounts. Alice Booker died six days after ceasing to drink beer; 13½ ounces of her viscera yielded 0·011 (one-ninetieth) grain of arsenic calculated as arsenious oxide—or 0·0002 per cent. This was an appreciable proportion. Mrs. Thompson died 32 days after ceasing to drink beer. Her viscera yielded arsenic in detectable but unweighable amount. In the case of Alice Riley, who died 14 days after ceasing to drink beer, and in the case of Margaret McCabe, who died 52 days after ceasing to drink beer, similar traces of arsenic were detected. In the case of Mary Jane Dyer, who died 23 days after ceasing to drink beer, no arsenic could be detected, though the symptoms during life were those of arsenic. She was obviously a heavy drinker and the organs showed the effects of advanced alcoholism, more especially in the liver and kidneys. Dr. Dixon Mann obtained comparable results on analysing other portions of the viscera of the five women. The analyses were conducted separately, but before the inquest he and Dr. Dixon Mann compared their results and found them substantially the same. It was interesting to note for what lengthened periods arsenic remained in the body. Ordinarily arsenic might be detected in the urine of persons to whom arsenic was administered very soon after it was taken, and for from one to three weeks after it had ceased to be taken. Exceptionally it might be found in the urine after longer periods. Obviously, as arsenic was largely excreted by the skin as well as by the urine, the fact that arsenic could no longer be detected in the urine was not proof that there was none present in the body. One remarkable symptom of those suffering from beer-poisoning which he observed was the pigmentation of the skin, which was pretty generally observed among the patients. When arsenical neuritis followed acute arsenical poisoning such pigmentation was by no means general. It had been asserted, denied, and re-asserted that arsenic lingered for lengthened periods in the bones of those to whom it had been administered. Others asserted that it remained longer in other organs than in the bones. Nothing definite could be asserted as to this beyond the fact that it lingered longest in the extravascular parts, such as the epidermis. It was even asserted that arsenic was a normal constituent of the human body, notably of the thymus and thyroid glands, and the skin. That arsenic was occasionally found in minimal amounts in the human body he knew from his own analyses, but he was of opinion that its presence was adventitious. It was not easy to ascertain that a person had never taken arsenic medicinally, and when one considered the innumerable avenues—food, drink, water, and the atmosphere—by which arsenic might be ingested it was not necessary in order to account for its presence to assume arsenic to be a normal constituent of the body. He could assert that in the majority of cases where he had tested various organs of the body for arsenic he had found none. Among the cases submitted to him by the Home Office and the Treasury he had occasionally found a little arsenic, but it was exceptional. He could not say that he had found it in the viscera of a healthy person. In consultation he saw a girl in Somerset who had been poisoned by arsenic. She had marked neuritis, could not walk, but he could discover no pigmentation in her skin. In another case a lady had had several doses of arsenic administered, and though she was very ill and her life was in danger she had no pigmentation. In the Hyères epidemic, where wine-drinkers were affected, pigmentation was a marked feature and, of course, pigmentation was known in connexion with arsenic given medicinally.

By Sir WILLIAM S. CHURCH: Arsenic was a poison which had engaged his attention very frequently clinically, pathologically, and analytically. Very frequently the symptoms that indicated arsenical poisoning were connected with the stomach and the intestines. The absence of gastric symptoms was calculated to make medical men slow in recognising that the case was likely to be one of arsenical poisoning. As to pigmentation there could be no doubt that when attention was called to this many patients were stripped and pigmentation was found in cases where it had not been expected. Except that it was very pronounced the neuritis did not appear to him to differ very much from what they had been acquainted with under the name of alcoholic neuritis. The general appearance of the patients was almost indistinguishable from what they would call alcoholic neuritis. The only patient whom he saw in a dying condition was in Crumpsall Infirmary and the patient was dying apparently from paralysis of the diaphragm. This year he had had to deal with a case of arsenical poisoning in which five out of seven or eight in one family were affected, and in that case he found extensive fatty degeneration without very great enlargement of the organ involved. The enlargement that had been so common in these cases in Manchester and Liverpool pointed to the probability of their being alcoholic as well as arsenical.

By Dr. WHITELEGGE: Do you regard alcohol as being a predisposing cause to arsenical poisoning?—I have had no opportunity previously to this epidemic of observing that.

In further examination Dr. STEVENSON said that exceptionally perhaps many articles of food might contain arsenic. The use of manures in the preparation of which arsenical sulphuric acid was employed must increase the chances of the admixture of arsenic with vegetables. Arsenic was said to have been found in cruciferous plants, such as turnips and cabbages, and even in potatoes. Many chalybeate waters were arsenical and the ferruginous deposits from waters that were good for drinking purposes often contained arsenic, even when the water itself was practically arsenic-free. Rivers from which drinking-water was obtained might contain arsenic, which frequently was cast into rivers from tanneries. Again, the application of arsenical substances to such things as apples and wines to destroy blight must result in the occasional ingestion of arsenic into the human body. The common use of arsenical sheep dips brought in the risk of introducing arsenic into our food supplies. Arsenic was given off during the burning of coal and coke containing arsenic. Soot was decidedly arsenical, and the soot-laden air of our cities was not destitute of arsenic, nor were smoked articles of food, such as ham, kippers, &c., chops, and grills. The method of preserving food by the use of borates introduced arsenic into food. He had met with no borax of commerce or boric acid quite free from arsenic. As these substances were used in the preservation of milk, cream, fish (fresh, salted, and dried), game, and even fresh meat, they had here another source of arsenic in the human body. He mentioned these sources of the introduction of arsenic into the body, not that he thought significant quantities of arsenic were thereby ingested, but to point out that some allowance must be made and some agreement come to as to the quantity of arsenic which was permissible in articles of food, drink, and drugs. There was a very varying susceptibility to arsenic among individuals. By far the larger number of adults could bear eight-minim doses of liquor arsenicalis three times a day for several weeks without the supervention of toxic symptoms—i.e., a dose of 0·22 grain arsenious oxide per diem. A few people could tolerate only a fraction of that amount without the appearance of distressing symptoms. But the same idiosyncracy was met with as to many drugs—chloral, opium, mercury, potassium iodide, &c., and even with respect to articles of food—onions, ginger, bananas, shell-fish, pork, and so on. In laying down restriction as to arsenic in food the idiosyncracy of persons with respect to it could not be fully met. He believed that 0·05 (1-20th) grain per diem was in the great majority of cases a safe quantity. As to the accumulative action of arsenic he wished to remark that the term cumulative, or accumulative poison, was a relative one. All poisons were, in a sense, cumulative. Even the rapidly excreted alkaloids, such as strychnine, showed a cumulative action when small safe doses were given at too brief intervals—i.e., before the major portion of the previous dose had been excreted. Arsenic was no more cumulative than other poisons which, like it, were rapidly excreted. When it was given in repeated small doses either tolerance was established—apparently a very rare occurrence—or input and output of the drug were balanced before a fatal dose accumulated in the body, or a toxic amount was retained in the body before input and output were balanced. If the daily dose were 0·22 grain—the ordinary full dosage—and one-fifth of the amount absorbed in the body were excreted per diem, when there was 0·9 grain in the body the input and output per diem would be balanced; and this condition would be arrived at in a fortnight. If, on the other hand, the daily excretion of arsenic were only one-tenth, input and output would be balanced when the body contained two grains; and this condition would be reached in about three weeks. But two grains might be a fatal dose. Certainly in the majority of cases in which arsenic was administered the daily excretion exceeded one-tenth of the arsenic taken. Dr. Stevenson, in conclusion, dealt with the detection of arsenic in beer and its quantitative determination. He gave the reasons which induced the Brewers' Commission to recommend the use of Reinsch's test. This test, he said, caused the rejection of beers containing more than one part of arsenic per 2,000,000 of beer, about one-thirteenth grain per gallon, and in skilled hands, he added, its delicacy was even greater than that. Using this test he found that by far the larger proportion of beers sold in London to the southern counties were arsenic-free, but that beers sold in several parts of the kingdom contained small quantities of arsenic—generally proportions which would not as he believed prove injurious to health.

The Commission then adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ABBOTT, C. E., M.R.C.S., L.R.C.P., and L.M. Irel., has been appointed Medical Officer to the No. 1 District of the Cheltenham Union, vice Beavan, deceased. Also Civil Medical Officer for Examining Army Recruits for Cheltenham.

ADAMS, JOSEPH DIXON, M.D. St. Andrew's, M.R.C.S., L.S.A., has been re-appointed District Medical Officer by the Langport (Somerset) Board of Guardians.

AHERN, JOHN M., L.R.C.P. Irel., L.R.C.S. Irel., L.M., has been appointed Assistant Medical Officer to the Warneford Asylum, Oxford.

BERRY, FREDERICK CHARLES, B.A., M.D., B.Ch. Trinity College, Dublin, has been re-appointed Medical Officer of Health for Burnham, Somerset.

COWAN, J. J., M.B., C.M. Edin., has been appointed District Medical Officer, Upton-upon-Severn Union.

ELLIOTT, C. N., M.B., M.Ch. Dubl., has been re-appointed Medical Officer of Health for the Thrapstone Rural District.

FAIRHALL, G. V. HAMLYN, M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Royal Alexandra Hospital for Sick Children, Dyke-road, Brighton.

FLETCHER, JAMES, M.B., C.M., D.P.H. Aberd., has been appointed Medical Superintendent to the Bristol City (Fever) Hospital.

FOX, T. C., M.B. Lond., F.R.C.P., M.R.C.S., has been appointed Dermatologist to the Bridge School, Witham, Metropolitan Asylum District.

HARPER, CHARLES, L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer of Health by the Bath Rural District Council.

HUTCHINSON, J. A., M.D. Durh., M.R.C.S., has been re-appointed Medical Officer of Health by the Northallerton Rural District Council.

INGLE, CHARLES D., L.R.C.P. Lond., M.R.C.S., has been re-appointed District Medical Officer by the Langport (Somerset) Board of Guardians.

KENNISH, T. L., M.D. Edin., has been re-appointed Medical Officer of Health, Winslow, Bucks.

KINGSFORD, B. H., M.B. Lond., M.R.C.S., L.R.C.P., has been appointed Certifying Factory Surgeon for the Woking District of Surrey.

LANGRAN, WILLIAM, L.R.C.P. & S. Edin., L.A.H. Dubl., has been appointed Medical Officer of Health by the Axminster Rural District Council.

LAWTON, F. C., M.R.C.S., has been appointed District Medical Officer, Malmesbury Union, vice W. R. Tolerton, resigned.

LINDSAY, F. W., L.R.C.P., L.R.C.S. Edin., has been re-appointed Honorary Surgeon, Victoria Eye and Ear Hospital, Hereford.

MAHOOD, ALLAN E., M.B. Irel., F.R.C.S. Eng., has been appointed Surgeon to the Bideford Infirmary.

MCLACHLAN, A. R., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Superintendent of the Infirmary, Brentford Union, and Assistant Medical Officer of the Schools, vice J. H. Reynolds, resigned.

MENZIES, J. M., M.B., C.M. Edin., has been appointed Medical Officer of Health, Long Sutton Urban District, vice R. Parkhurst, resigned.

MUDGE, ZACHARY BELLING, L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Phillack (Cornwall) Urban District Council.

NANCE, H. C., F.R.C.S. Eng., has been appointed Surgeon to the Jenny Lind Infirmary for Sick Children, Norwich.

PITTS-TUCKER, F. A., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer, Ely Union, vice M. J. Tulk, resigned.

RENSHAW, I., L.D.S. Irel., has been appointed Dentist to the Cottage Homes, Rochdale Union.

RICHARDS, S. H., M.B., C.M. Edin., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer, Middlesborough Union, vice W. Knott, resigned.

ROBERTS LLEWELYN, M.D. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer to the Great Western Collieries, Pontypridd, vice J. L. Leckie.

SANDOE, JOHN WORDEN, M.D., B.S. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Broadclyst District of the St. Thomas's (Exeter) Union, vice James Somer, resigned.

SCARR, JOHN, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer to the Cottage Homes, Rochdale Union.

SMALLWOOD, M. E., L.R.C.P. Lond., M.R.C.S., has been appointed Second Assistant Medical Officer to the Infirmary, parish of St. Leonard, Shoreditch, London.

SPRAKELING, R. J., M.R.C.S., has been re-appointed Medical Officer of Health for the Borough of Bootle.

STANSFIELD, F. W., M.D., Ch.B. Vict., D.P.H. Camb., has been appointed Public Vaccinator to the Reading Union, vice O. Lowsley, deceased.

SUTCLIFFE, WM., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer, South-East District, West Bromwich Union, vice H. Sutcliffe, resigned.

THOMAS, DAVID JONES, L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Merthyr Tydvil District Council.

THOMPSON, WALTER, L.R.C.P. Lond., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Leeds Public Dispensary.

TINLEY, E. F., M.D. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Whitby Urban District Council.

WALKER, J. F., L.R.C.P. Lond., M.R.C.S., has been appointed First Assistant Medical Officer to the Infirmary, Whitechapel Union, vice H. G. Ellery, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ASYLUM FOR IMBECILES, Leavesden, Kings Langley, Herts.—Senior Assistant Medical Officer, unmarried. Salary £250 per annum, with rations, lodging attendance, and washing.

BRISLINGTON HOUSE PRIVATE ASYLUM, N. Bristol. Second Resident Medical Officer, unmarried. Salary £150, board, lodgings, and washing.

BRISTOL GENERAL HOSPITAL.—Assistant House Surgeon and a Casualty House Surgeon. Salary £50 per annum, with board, residence, &c.

CARDIFF INFIRMARY.—Assistant House Physician for six months, renewable. Salary at the rate of £75 per annum, with board, washing, and apartments.

CATERHAM ASYLUM FOR IMBECILES, Caterham, Surrey.—Medical Superintendent. Salary £600 per annum, rising £50 annually to £800, with unfurnished house, coals, gas, washing, milk, and vegetables.

CHELSEA, BROMPTON, and BELGRAVE DISPENSARY, 41, Sloane-square, S.W.—Honorary Physician.

CHELSEA INFIRMARY, Cale-street.—Temporary Second Assistant Medical Officer, age not to exceed thirty years. Salary at the rate of £70 a year, with furnished apartments, rations, washing, coals, and gas, and £3 10s. a year in lieu of beer.

CORPORATION OF MANCHESTER.—Junior Assistant to the Medical Officer of Health. Salary £200 per annum.

DOVER HOSPITAL.—House Surgeon, unmarried. Salary £100 a year, increasing after 12 months' service, with board, lodging, and washing.

EASTERN DISPENSARY OF BATH.—Resident Medical Practitioner. Salary £130 per annum, with furnished apartments, coals, gas, and domestic attendance.

EAST SUFFOLK AND IPSWICH HOSPITAL.—Two House Surgeons, unmarried. Salaries £110 for Senior and £80 for Second House Surgeon, with board, lodging, and washing.

ECCLESALL BIERLOW UNION.—Resident Medical Officer. Salary £130 per annum, with board, lodging, and attendance.

FRENCH HOSPITAL AND DISPENSARY, 172, Shaftesbury-avenue, W.C.—Resident Medical Officer, speaking French, unmarried. Salary £80 a year, with full board.

GENERAL INFIRMARY, Leeds.—Resident Ophthalmic Officer. Salary £50 a year, with board and lodging.

GLAMORGAN COUNTY ASYLUM.—Junior Medical Officer, unmarried, not over thirty. Salary £150, with board, lodging, washing, and attendance.

GOVAN DISTRICT ASYLUM, Crookston, near Paisley, N.B.—Senior Assistant Medical Officer. Salary to begin at £150 a year, with rooms, board, laundry, and attendance.

GUEST HOSPITAL, Dudley.—Senior Resident Medical Officer. Salary £100 per annum, increasing to £120, with board, residence, attendance, and washing.

HAMPSTEAD HOSPITAL.—Resident Medical Officer for six months, eligible for re-election. Salary at the rate of £120 per annum, with rooms, coals, and gas.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians for six months, with honorarium of £25.

HOSPITAL FOR WOMEN, Soho-square.—House Physician for six months. Salary £30

HULL ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £60, with board and lodging.

JESSOP HOSPITAL FOR WOMEN, Sheffield.—House Surgeon, unmarried. Salary £50 per annum, with board, lodging, and washing.

LONDON COUNTY ASYLUM, Hanwell, W.—Dispenser. Salary £110 per annum, rising by £10 a year to £150, with dinner.

LONDON OPEN-AIR SANATORIUM, Pinewood, near Bracknell, Berkshire.—Resident Physician, unmarried. Salary £200, with furnished apartments, board, attendance, and washing.

MANCHESTER PORT SANITARY AUTHORITY.—Port Medical Officer. Salary £350 per annum.

MANCHESTER ROYAL INFIRMARY.—Resident Surgical Officer, unmarried. Salary £150 per annum, with board and residence. Also Assistant Director in the Clinical Laboratory. Salary £50 per annum.

NORFOLK AND NORWICH HOSPITAL.—House Physician for two years. Salary £80 per annum, with board, residence, &c.

NORTHAMPTON GENERAL INFIRMARY.—Physician, not under twenty-five years of age.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Dental Surgeon.

PATHOLOGICAL DEPARTMENT, YORKSHIRE COLLEGE, Leeds.—Junior Demonstrator. Salary £120.

ROTHERHAM HOSPITAL.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ROYAL ALBERT HOSPITAL, Devonport.—Resident Medical Officer, unmarried. Salary £110 per annum, with board and lodging.

ROYAL SEA BATHING HOSPITAL, Margate.—Assistant Resident Surgeon. Salary £60 per annum, with board and residence.

ROYAL SOUTHERN HOSPITAL, Liverpool.—House Surgeon. Salary 60 guineas per annum, with board and residence.

ROYAL SURREY COUNTY HOSPITAL, Guildford.—Resident House Surgeon. Salary £80, board, residence, and laundry.

SCARBOROUGH HOSPITAL.—Assistant House Surgeon for three months. Salary £75, with residence, board, and washing; if approved, to be Senior for twelve months. Salary £90, with residence, board, and washing.

ST. MARY'S HOSPITAL, Paddington, W.—Ophthalmic Surgeon.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary at rate of £24 per annum, with board, washing, and residence.

SUFFOLK GENERAL HOSPITAL.—House Surgeon. Salary £100 a year, with board, lodging, and washing.

TOTTENHAM HOSPITAL.—Honorary Surgeon. Also Assistant Honorary Physician.

TUNBRIDGE WELLS GENERAL HOSPITAL.—Resident House Surgeon, unmarried. Salary £100 per annum, with board, furnished apartments, gas, firing, and attendance.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W., and the VICTORIA CONVALESCENT HOME, Broadstairs.—House Physician for six months. Honorarium of £25, and board and lodging in the Hospital.

VICTORIA HOSPITAL, Folkestone.—House Surgeon. Salary £100 per annum with board, residence, and laundry.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon. Salary £75 per annum, with board, residence, &c.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Assistant House Surgeon for two months, to be followed by six months as House Surgeon.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Assistant House Physician for six months. Honorarium at rate of £75 per annum, with board, lodging, and washing.

WREXHAM INFIRMARY.—House Surgeon. Salary £100 per annum, with board and washing.

Births, Marriages, and Deaths.

BIRTHS.

ALLEN.—On March 17th, at Gipsy-lane, Forest-gate, E., the wife of R. Hugh Allen, M.B., of a daughter.

DUDFIELD.—On March 17th, at Blomfield-road, Maida-vale, W., the wife of Reginald Dudfield, M.A., M.B., of a son.

HUMPHERY.—On March 11th, at Wellgarth House, Armley, Leeds, the wife of Geoffrey Percy Humphery, M.B., C.M., of a daughter.

OWEN.—On March 18th, at St. Alban's-place, Blackburn, the wife of O. Trafford Owen, M.B. Edin., of a son.

SHACKEL.—On March 17th, at Brand House, Ludlow, the wife of G. A. Shackel, L.R.C.P., M.R.C.S., of a son.

MARRIAGES.

HASSALL—LORAINE.—On the 14th instant, at St. John's Church, Chester, by the Rev. Canon Scott, assisted by the Rev. C. Packer, John M. Hassall, M.D., of Northwich, to Sophia Jane, widow of the late George S. Loraine, of Estancia Sta. Maria, Queguay Uruguay.

JAMIESON—MILNES.—On 20th March, at St. Andrew's Cathedral, Singapore, by Rev. D. Holland Stubbs, T. Hill Jamieson, M.B., C.M. Edin., of Penang, to Mary, eldest daughter of J. Milnes, Esq., Huddersfield, Yorkshire.

DEATHS.

ROGERS.—On March 14th, at Upper Baker-street, N.W., William Richard Rogers, M.D., M.R.C.P. Lond., and M.R.C.S., aged 84 years.

SAUNDERS.—On March 15th, at Fairlawn, Wimbledon-common, Sir Edwin Saunders, F.R.C.S., aged 87 years.

WEDMORE.—On the 13th March, at Chapmanslade, Wilts, Charles Ernest Wedmore, M.A., M.B. Cantab., M.R.C.S. Eng., third son of the late Thomas Wedmore, Esq., J.P., of Druids' Stoke, Bristol, aged 50 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PECULIAR PEOPLE AGAIN.

AN inquest held recently at Canning Town on the body of a child, 10 months old, who had died from pneumonia, brought to light most of the circumstances which usually attend the deaths of children whose parents belong to the sect known as the Peculiar People. The child became ill, and so an elderly woman was called in to give advice. The elderly woman was apparently one of the Peculiar People accustomed to nurse members of her sect, while her opinion was valued on account of her age, and she made suggestions as to the child's diet. The child grew obviously worse, and the elder of the Church, who does not appear to have been a witness before the coroner, was summoned, and he, according to the usage of his sect, laid hands upon the child and prayed. So the child died without medical aid, which might have saved the child's life, and as the medical man who made the post-mortem examination very properly declined to say positively and on oath with regard to an infant whom he had never seen alive that if called in he could have saved the infant's life, the jury returned a verdict of "Death from natural causes," at the same time censuring the parents for their neglect. In the course of the inquiry the coroner, Mr. G. E. Hilleary, and one or two jurors tried to rouse in the child's parents a sense of the melancholy absurdity of their conduct, but in vain. For example, to a suggestion that the Bible says, "Those that are sick need a physician," the witness replied, "I beg your pardon, it says, 'They that are whole need not a physician,'" an answer which shows that others besides the enemy of mankind can dislocate and misquote Scripture to suit their own purposes and to support their perversity. We agree with a juror who ejaculated "It's all bosh," but at the same time it is very dangerous bosh and very difficult to deal with. We called attention recently to the law in an American State which forbids persons, who are not scientifically qualified, to pretend to heal disease. It would probably be difficult to deal with the elders of the Peculiar People without importing the element of religious persecution, but it would be much more just that they should suffer than the parents whom they instruct in their views and whose children they pretend to heal. The parents are now held responsible, if anyone is, when a child dies or suffers unnecessarily; when a grown-up person does so neither the elder nor anyone else suffers more than the ineffectual censure of a coroner's jury.

A HARD CASE.

To the Editors of THE LANCET.

SIRS,—I should like your opinion on the following case:—My practice being for sale, a gentleman came to see me, and after going fully into matters agreed to purchase the lease of the house and the practice. The purchaser's father, being a solicitor, prepared all the papers and arranged a day for settlement. Meanwhile a house became vacant almost next door to mine, when the purchaser's father, thinking it a suitable house, threw me over on the day arranged for settlement and took the other house. My solicitor says that I have no redress, having no signed papers, although all was prepared for signature. I believe it will be the opinion of the profession that such action should merit disapproval. I am, Sirs, yours faithfully,

M.R.C.S. ENG.

*** If our correspondent states his exact experience he has been treated very shabbily.—ED. L.

TENBY COTTAGE HOSPITAL AND ITS OUT-PATIENT SYSTEM.

AT the annual meeting of the governors of the above institution which was held on Jan. 25th a discussion arose as to the arrangements for seeing out-patients. They seem somewhat haphazard, or, as Mr. B. Harries, a member of the committee, put it, "There was not much red-tape about the hospital." So far as we understand the report, if an out-patient should come at a day and an hour when one of the medical staff happens to be in the hospital he is seen by the medical man in question. If, however, the patient should come when a medical man is not there he is attended to by the matron. Dr. D. A. Reid, who is a member of the medical staff, said that the medical staff ought to do the work and to attend regularly. The mayor thought that in that case everyone who was sick would go to the hospital and that the practitioners in the town would suffer. Dr. Reid, however, did not agree with this suggestion and proposed that the secretary should communicate with the practitioners in the town and ask them if they would fall in with the scheme. It was agreed that this should be done. In a letter from Dr Reid, which appears in the *Tenby and County News* of March 6th, it is stated that the three members of the staff who were not present at the annual meeting all declined to support Dr. Reid's ideas. We can only say that to our minds the position is a most unfortunate one. We do not doubt the matron's ability to dress a cut finger or a cut head, but one of these days a cut finger will develop tetanus or a patient with apparently only a cut head will turn out to have a fractured skull from which he will very possibly die. The members of the staff who agree in allowing the patients of an institution of which they are in medical charge to be treated by an unqualified person without their supervision are sailing perilously near the reef of "covering." There is one passage in Dr. Reid's letter to which we are quite unable to agree. He says: "If the subscribers were provided with out-patient tickets as at other hospitals and dispensaries, all fear of the charity being abused would be removed." If this is really the case the hospital subscribers of Tenby must be of a very different nature from those of other towns, for in our experience the average hospital subscriber is only too ready to give a letter to anyone who asks, without any inquiry as to the fitness of the recipient for charitable relief.

RAMPANT QUACKERY.

WE have received from a correspondent the following documents bearing upon a quack business which is carried on apparently in a way by no means creditable to its proprietors: two pages from the *Sydney Bulletin* of Dec. 15th, 1900, and Jan. 12th, 1901, a letter in answer to a correspondent containing a Diagnosis Form, and a little two-leaved circular containing qualifications and testimonials. The documents emanate from a firm of quacks calling themselves "Drs. Freeman and Wallace, Authors, Lecturers, and Scientific Analysts, the World-famed Specialists, Specialties, Nervous and Private Complaints, Blood and Skin Diseases." "Dr." Freeman describes himself as Director of the Freeman and Wallace Electro, Medical, and Surgical Institute, and as of Dr. Harmon's College, Cor. Cal., U.S.A.; while "Dr." Wallace sets forth that he is chief consulting staff, L.R.C.P.E., L.P.S.G., L.M.R.C.E., M.D. Cal. Now with Freeman we have nothing to do, but it is obvious that if Wallace is really what he purports to be the licensing bodies whose diplomas he abuses should take steps to remove him from their roll. The diagnosis form contains the usual mis-statements and 52 questions in all, dealing mainly with sexual hypochondriasis. Question 52 is possibly the most important—namely, "Have you inclosed our fee of £1?" The letter to the patient is, we must say, a very cunningly-worded document. Take the following passage. It commences by saying: "We are forwarding to you by this post a copy of our new pamphlet on Nervous and Private Complaints. ..... If you are in perfect health we trust the work will prove sufficiently interesting to warrant a careful perusal. If, on the other hand, you are in doubt as to whether you require medical advice you should carefully examine your morning's urine; if after remaining stationary for two days and nights it be clear, it is most probable your organs are in a healthy condition, but if not clear you should answer the questions and we will forward our opinion by return of post." We also learn from the advertisement in the *Bulletin* of Jan. 12th, 1901, that "The Freeman and Wallace Electro, Medical, and Surgical Institute consulting staff rise superior to the false code of ethics which tyrannically bind (*sic*) the medical profession ....." Wallace, we may add, claims to have a testimonial from Sir J. Dominic Corrigan. Freeman and Wallace are evidently quacks of the worst type, but there are always fools who will continue to go to such. We have called the letter to the patient a cunningly-worded document; it is worse, it is a lying document, for it implies that the urine becoming cloudy after two days' standing is a sign of disease. Now we have no hesitation in stating that if the urine of 1000 healthy persons were taken and allowed to stand for two days in practically every case it would become cloudy either from alkaline decomposition and deposit of phosphates, or from deposition of mucus or of urates.

LEGITIMATE OR ILLEGITIMATE COMPETITION.

To the Editors of THE LANCET.

SIRS,—In a small country town A sells his practice to B. Immediately on B taking over the practice, A having cleared out, C, a neighbouring practitioner, takes in a partner D and places D in the small town where B lives. I may add that C resides three miles away from D. Kindly give your opinion as to whether C and D have acted strictly in accordance with the usual professional etiquette towards their brother practitioner B.—I am, Sirs, yours faithfully,

March, 1901. JUSTICE.

*** There can be no doubt that C's action, taken immediately upon the departure of A, was directed to obtaining some of the practice recently transferred by A to B; but it is difficult to say that such action is necessarily unprofessional. Medical men are certainly, to some extent, in competition with each other, and we must make allowances for individual views on what is and what is not correct conduct towards a fellow practitioner. Many men would not have liked to do what C and D have done, but as many would consider their course one of legitimate enterprise. In matters where there can be no hard-and-fast law every man must be a rule to himself.—ED. L.

THE PROGRESSIVE MEDICAL ALLIANCE.

To the Editors of THE LANCET.

SIRS,—I inclose a circular which was handed to me in Oxford-street one day last week. It is unnecessary to comment on this from a point of view of professional morality—it speaks for itself, but it is at least a matter for wonder that associations like the Medical Defence Union and others of a kindred character allow such grave abuses to remain without apparently any effort to remove them. In more than one of the London weeklies there are to be seen advertisements of "hospitals" and "dispensaries" managed by "highly and fully qualified medical men," and such advertisements have appeared regularly for some considerable time. Surely something can be done to put a stop to practices

which are a disgrace to the profession and do so much to degrade it in the eyes of the public. Either the statements contained in these circulars are true or they are not. If they are true and the men in charge of these places are really qualified and registered medical men, then no time should be lost in bringing the matter before the General Medical Council with a view to having the names of men who have so far dishonoured their profession struck off its rolls; if they are not, surely it is the business of societies formed for the protection of the profession and the public to expose the falsehood.—I am, Sirs, yours faithfully,

March 15th, 1901 FAIR PLAY.

*** "Fair Play" has come across our old friend the Progressive Medical Alliance. We refer him and others of our readers who may be interested in this institution to THE LANCET of Sept. 29th, 1900, p. 981, and of Jan. 19th, 1901, p. 224. Unless some such steps as we, and "Fair Play" (in the above letter), suggest are taken it is of little use to say anything in these columns about such quack establishments, with a view that is of keeping people away from them. For the class of person who wastes his time and money at the Progressive Medical Alliance does not read THE LANCET.—ED. L.

HOW INFECTION IS SPREAD.

THE gross carelessness and disregard of duty towards one's neighbour which exists among certain members of the community was well exemplified by a case which occurred at Birmingham recently. A woman brought a child for treatment to the General Hospital at Birmingham and the child was at once recognised to be suffering from scarlet fever. The woman, it is reported, was told to stand on one side until the health authorities had been communicated with and the child could be removed to the fever hospital. On the arrival of the ambulance, however, both mother and child had disappeared. She was accordingly sought under the name and at the address which she had given at the hospital, but the address was found to be false, and no one in the street knew anything of either mother or child. However, Mr. Parker, the superintendent of the health department, took up the matter and after diligent search the woman was found and the child was removed to the fever hospital. The room which she occupied was a small attic in a house containing a number of other children. Ignorance is, of course, no excuse in the eye of the law, and we presume that the woman was told at the hospital what was the matter with the child. She is presumably poor, being a hospital patient, but we hope that the sanitary authorities will, as well as taking steps for the disinfection of the house in which she lived, summon her before the magistrate for exposing her child, when, even if on account of her poverty she be not punished, she will learn that no one has a right to expose his or her neighbour to the risk of contracting so severe an infectious disease as scarlet fever.

MALE PROBATIONER NURSES FOR MENTAL CASES.

To the Editors of THE LANCET.

SIRS,—Can you or any of your readers inform me of any hospital or institution where male probationers are taken to train as mental nurses. I am, Sirs, yours faithfully,

March 15th, 1901. H. B.

"MEMORIAL TO THE LATE DR. ARCHIBALD HAMILTON JACOB."

Cheques and postal orders are to be made payable to the honorary treasurers (Sir Charles A. Cameron, C.B., 51, Pembroke-road, Dublin, and Mr. L. H. Ormsby, Vice-President of the Royal College of Surgeons in Ireland, 92, Merrion-square, Dublin), and crossed "Ulster Bank." The honorary secretary is Mr. George F. Blake, J.P., Registrar of the Royal College of Surgeons, Dublin.

THE FRIENDLY SOCIETIES' ANNUAL CONFERENCE.

THE annual conference of delegates from the 33 friendly societies in the United Kingdom was held at Birmingham on March 14th. Mr. J. J. Stockall was in the chair and the vice-chairman was the Rev. Frome Wilkinson. The Lord Mayor of Birmingham attended the opening of the proceedings and welcomed the delegates in the name of the city. Reports were presented by Mr. J. L. Stead and Mr. Cleveland, the conference secretary, who had been appointed to act as arbitrators to meet representatives of the General Medical Council at a meeting which was held in London on March 13th. (We are quoting from the report in the *Birmingham Gazette* of March 15th, but we fancy that the meeting referred to was a conference with the British Medical Association and not with the General Medical Council.) Be this as it may, Mr. Stead is reported as saying that "the doctors' representatives denied that the question of a 'wage-limit' had been settled, so that they were practically in the same position as they were three years ago." After the shorthand report of the reply of the medical men had been read Mr. Sandford (Foresters) moved a proposal urging the meeting to make a firm stand against the wage-limit. Mr. Hulse (Foresters) said that in some parts of the country he regretted that friendly societies did not pay their doctors a reasonable sum. The President said that they had admitted this to the medical men and he hoped that the mention of this fact would induce those societies which underpaid their medical men to do differently. This remark was greeted with "Hear, hear." Finally, Mr. Sandford withdrew his motion, but one was adopted to the effect that the conference could not under any circumstances agree to a wage-limit, while the arbitrators were to be re-appointed to continue the conferences with the medical men.

Despite the resolution about the wage-limit we must say that the meeting showed more hope of some satisfactory decision being arrived at in the future than former meetings have done. It is no light thing for a conference of friendly societies to allow that medical men can be underpaid. But as regards the wage-limit we seem to have arrived at an *impasse*, and we can only hope that the next conference between the societies and the profession will be productive of some good result. If a wage-limit is to be barred why should not a graduated scale of payments be adopted? There is no reason why a working man with 20*s.* a week should pay the same as one who earns 60*s.* If the former is to pay 1½*d.* per week the latter might well be asked to pay at least 4*d.* per week.

A DEPARTURE IN ANNUAL REPORTS.

WE have received a copy of the twenty-first annual report of the Evesham Cottage Hospital, from which it appears that the hospital is doing good and increasing work. But our attention has been caught by an innovation in hospital reports which merits distinct disapproval. Under the epitome of cases it is stated that 38 successful operations were performed, 18 major and 20 minor. The 38 are then further subdivided by being allocated to four members of the staff, so that the public may learn that Mr. A and Mr. B had two successful operations each, while Mr. C had four and Mr. D the remaining 30. Such publicity must be unpleasant for Mr. D, for laymen can hardly fail to consider that he is 15 times as good a surgeon as Mr. A or Mr. B, and seven and a half times as good as Mr. C. Evesham Cottage Hospital is a small place and the harm done by publishing such a table may be proportionately small, but if hospital statistics of this sort are going to be made public in annual reports great harm and great injustice may follow. In this case we are sorry for Mr. D, who has been advertised at the expense of his colleagues.

Inquirer.—Dr. James Barry, Inspector-General of Army Hospitals, is always described as M.D. She was certainly educated in Edinburgh and was probably an M.D. of that university. The evidence points in this direction though we believe the source of Dr. Barry's degree has not been definitely settled. The Act which brought the Medical Register into existence had not been passed when Dr. Barry joined the Army.

Justicia.—In our opinion the fees should belong to A from the time that the purchase-money is paid. The matter is one for mutual arrangement.

THURSDAY (28th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (30th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (25th).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish quare, W.).—8.30 P.M. Mr. T. H. Kellock: Two Cases of Abdominal Injury with Rupture of Viscera.—Mr. H. F. Waterhouse: A Case of Lateral Sinus Pyæmia and Cerebellar Abscess with Development of Cheyne-Stokes Breathing and Cessation of Respiration under Anæsthesia, Recovery after Two Operations.

TUESDAY (26th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—Paper:—Dr. W. Hunter: A Case of Pernicious Anæmia, with Observations regarding Mode of Onset, Clinical Features, Infective Nature, Prognosis, and Antiseptic and Serum Treatment of the Disease.

WEDNESDAY (27th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 P.M. Paper:—Dr. W. H. Kelson.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—4.30 P.M. Informal Exhibition of Cases. 5 P.M. Meeting.

THURSDAY (28th).—CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret-street, W.).—8 P.M. Dr. F. Warner: Observations of Children after the Methods of Natural History.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (25th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C. Stewart: The Protection and Nourishment of the Young of the Vertebrata, and some New Additions to the Museum.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. A. Whitfield: Consultation. (Skin.)

TUESDAY (26th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. J. F. Payne: On Cancer, especially of the Internal Organs. (Lumleian Lectures.)

THE BROWN ANIMAL SANATORY INSTITUTION (University of London, South Kensington, S.W.).—5 P.M. Dr. J. Rose Bradford (Professor-Superintendent): The Protozoa in their Relation to Disease, with especial reference to the so-called Tsetse-Fly Disease of South Africa.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—5.30 P.M. Annual General Meeting.

WEDNESDAY (27th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C. Stewart: The Protection and Nourishment of the Young of the Vertebrata, and some New Additions to the Museum.

LONDON THROAT HOSPITAL (204, Great Portland-street, W.).—5 P.M. Mr. C. Woakes: Selected Cases. (Post-Graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Acland: Bronchiectasis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Smith: Consultation. (Surgical.)

THURSDAY (28th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. J. F. Payne: On Cancer, especially of the Internal Organs. (Lumleian Lectures.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Hutchison: A Lantern Demonstration.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Consultation. (Surgical.)

THE HOSPITAL FOR DISEASES OF THE SKIN (Stamford-street, Blackfriars).—3 P.M. Clinical Demonstration: Dr. P. S. Abraham.

FRIDAY (29th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C. Stewart: The Protection and Nourishment of the Young of the Vertebrata, and some New Additions to the Museum.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. H. Tilley: Consultation. (Throat.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières Paris.

The Hunterian Lectures
ON
THE TOPOGRAPHICAL ANATOMY OF THE ABDOMINAL VISCERA IN MAN.

Delivered before the Royal College of Surgeons of England on March 4th, 6th, and 8th, 1901,

BY CHRISTOPHER ADDISON, M.D. LOND., F.R.C.S. ENG.,
PROFESSOR OF ANATOMY AT THE UNIVERSITY COLLEGE, SHEFFIELD.

LECTURE II.[1]

Delivered on March 6th.

MR. PRESIDENT AND GENTLEMEN,—At the conclusion of the last lecture we noticed: (1) that when the stomach is high in the abdomen the liver also is found high up and placed well under cover of the ribs, and in these cases also the transverse colon is generally high in the abdomen and mostly distended, and, in many cases, it passes upwards in front of the stomach into the vault of the diaphragm; (2) that the stomach may be distended without coming much lower in the abdomen, but that in the cases in which a distended stomach (usually of a cylindrical shape) extends low down in the abdomen, with the liver maintaining its normal level, the pylorus will not be displaced downwards to any material extent; and (3) that when the liver is enlarged and extends low down in the abdomen, the pylorus will be found low down, as well as, usually, the main part of the body of the stomach. These conclusions are further reinforced by considering the

LATERAL DISPLACEMENTS OF THE PYLORUS.

By means of the strong right part of the lesser omentum and the structures contained within it the first part of the duodenum with the pylorus is firmly held up to the under surface of the liver, and the position and obliquity of the pylorus by that means largely determined. In 34 cases the pylorus was on the middle line or to the right of it and in six cases to the left of it. The first group of 34 cases contains 14 cases in which the pylorus was on the middle line or not more than two centimetres to the right of it; in a further 14 cases it varied from two to four centimetres to the right; and in six extreme cases it was more than four centimetres—up to six centimetres—to the right of the middle line. The six cases in which the pylorus was to the left of the middle line varied up to 3·5 centimetres to the left. So that in 45 per cent. of the cases the upper border of the pylorus was not more than two centimetres from the middle line to one side or the other, and in 22·5 per cent. it was on the middle line or to the left of it. (The measurements relate in all cases to the upper border of the pylorus.) The direction of the pylorus was practically vertical in 60 per cent. of the cases, oblique in 25 per cent., and transverse in 15 per cent.

Displacements to the left.—In all but one of the cases in which the pylorus was on the middle line or to the left of it the liver extended low down and far over to the left at a low level and in the remaining case had a very massive omental tuberosity fitting into the lesser curvature of the stomach, although the lower border of the liver did not extend to the left of the middle line in the plane of the upper border of the pylorus. These cases almost warrant us in saying *that when the liver is enlarged and spreads downwards across the abdomen at a low level we may expect to find the pylorus on the middle line or to the left thereof.* An examination of these cases does not lead to the conclusion that a pylorus to the left of its normal situation is particularly associated with an empty condition of the stomach, but if we look at those cases in which the pylorus was situated more than 3·5 centimetres to the right of the mid-line we find that they are specially associated with a well-filled or distended condition of the stomach.

Displacements to the right.—Professor J. Symington[2] pointed out that the left overhanging part of the liver is tilted upwards and to the right on its long left lateral ligament by the filling stomach. If this ligament be long and membranous the distended stomach can the more readily tilt the liver upwards and to the right and insinuate itself further to the right beneath the liver. The strong portion of the lesser omentum attaching the pylorus to the under surface of the liver has an obliquity downwards and to the left and would not resist a considerable movement in a right direction. A fair guide to the degree of lateral movement the liver has undergone may be obtained by noticing the situation and direction of the attachment of the falciform ligament to its anterior surface. On the diagrams of the liver, with the exception of a few of the early cases in which the point was unfortunately omitted, the attachment of the falciform ligament is indicated by interrupted lines. Those cases in which the pylorus was situated further to the right than usual are so uniform in the conditions they present of a well-filled or distended stomach (especially one that did not come much lower than usual in the abdomen), with the liver tilted upwards and to the right, so as to lie more or less completely under the right costal arch, that they may be sufficiently represented in tabular form.

Table showing the Conditions when the Pylorus is Displaced to the Right.

Case. No.	Distance to right of middle line of the upper border of the pylorus.		Remarks.
2	3·5	centimetres.	Stomach distended and low. Liver* a little tilted, low, and somewhat enlarged. Colon, no special feature.
14		,,	Stomach full. Liver tilted. Colon very distended, pressing up the stomach.
21		,,	All points the same as No. 14.
26		,,	Stomach full, thrown into folds. Liver not much tilted. Transverse colon normal.
27		,,	Stomach moderately filled. Stomach and liver both pushed down by intra-thoracic growth. Liver not tilted. Colon very tortuous and distended.
11	4	,,	Stomach full. Liver tilted.
28		,,	Stomach distended. Liver tilted and much pushed over to the right. Colon distended.
29		,,	Ditto in all respects.
5	4·5	,,	Stomach full. Liver and stomach pushed up and to the right by distended colon and intestines.
10		,,	Stomach very distended. Liver pushed almost entirely to the right of the middle line.
32		,,	Stomach very distended. Liver much tilted. Transverse colon prolapsed.
28		,,	Stomach very distended. Liver tilted.
35	5	,,	Stomach partly filled, thrown into folds. Liver and stomach both pushed upwards and to the right by an enormously distended colon. Liver almost entirely to the right of the middle line.
4	6	,,	Stomach distended. Liver large, not much tilted to the right. Colon low and tortuous.

* The tilting of the liver is of the left lobe to the right and upwards.

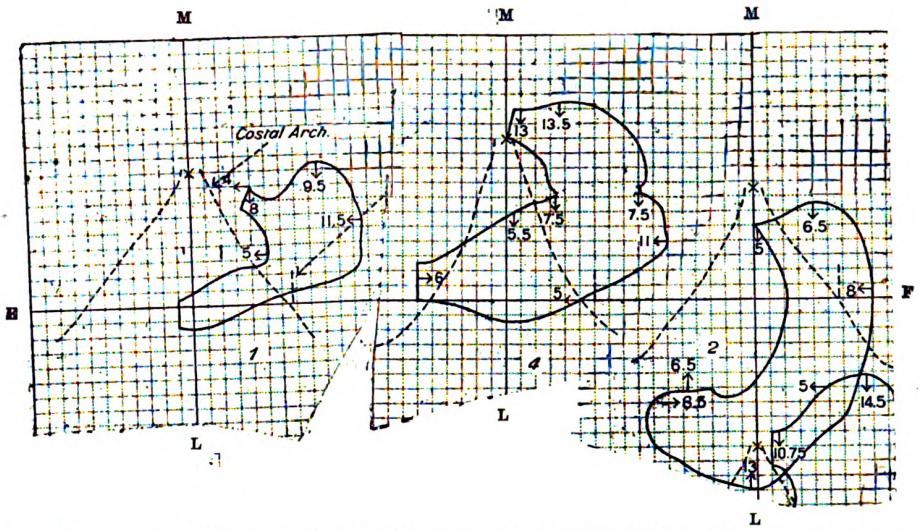
These cases, however, by no means include all those in which the stomach was distended.

MOVEMENTS OF THE STOMACH.

Although there were so many cases in which the stomach was well filled or distended there was only one example of the condition, figured by Symington as that of the normal distended stomach, in which the pylorus is situated behind a portion of the body of the stomach which extends further to the right than the pylorus on an anterior plane. It is doubtful if the pylorus moves more than two centimetres to the right in the course of filling of the stomach if it moves at all. In filling of the stomach the large hollow to the left behind is apparently first occupied, then the greater curvature in front, to the left of and below the liver, comes to the anterior abdominal wall, at the same time tilting upwards and to the right in some measure the left lobe of the liver, and directing the lesser curvature more to the right and backwards; then, if necessary, the stomach extends somewhat to the right, downwards and forwards, pressing down

[1] Lecture I. was published in THE LANCET of March 16th, 1901, p. 759.
[2] On Certain Variations in the Shape, &c., of the Liver, Edinburgh Medical Journal, 1888.

FIG. 4.



The stomachs for Cases 1, 4, and 2 shown on the reduced scale about the middle line (M, L) and the upper transverse abdominal line (E, F). Case 1 is an example of the type of stomach with a cylindrical portion towards the pyloric end. Case 4 is a good example of the constriction which is commonly found along the left border. Case 2 shows the cylindrical stomach of chronic distension displaced downwards by an enlarged liver. The figures indicate the distance in centimetres from the surface lines.

FIG. 5A.

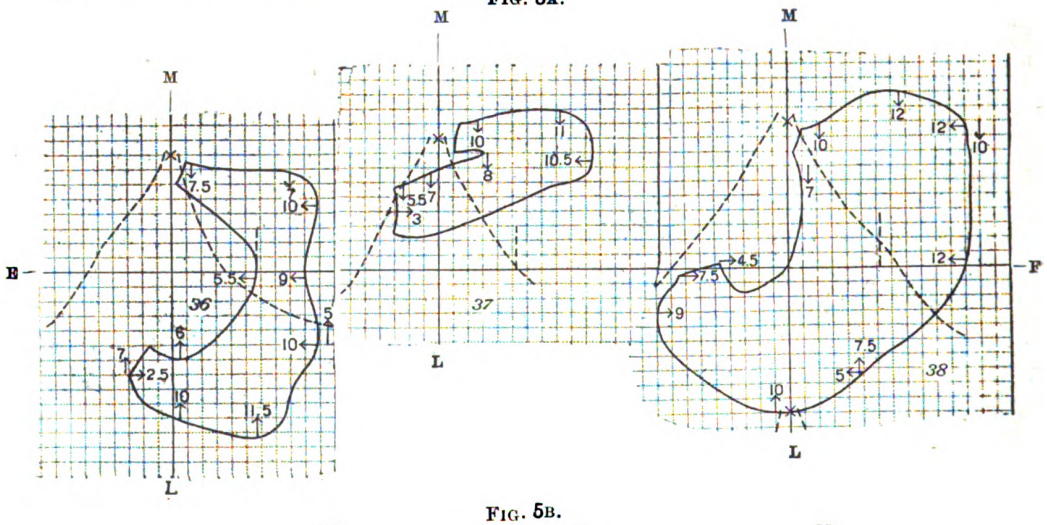


FIG. 5B.

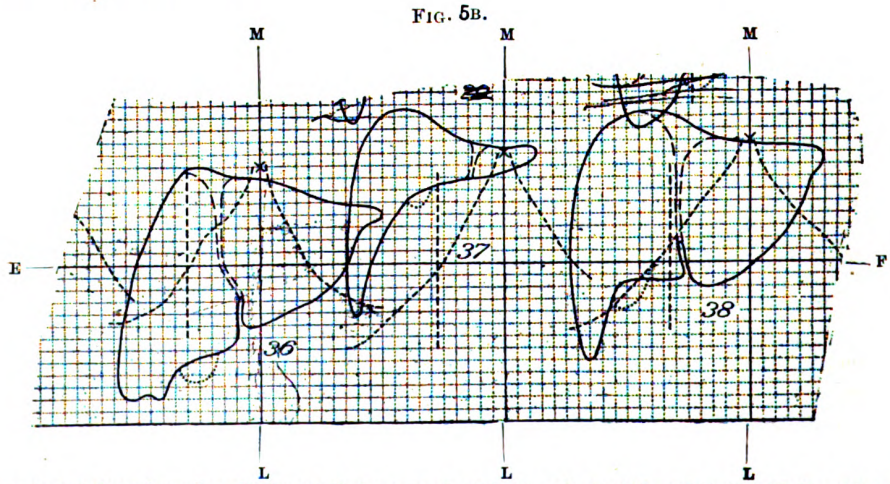


The stomachs and livers from Cases 36, 37, and 38 shown on the reduced scale about the middle line (M, L) and the upper transverse abdominal line (E, F). Case 36 shows the displacement of the pylorus when the liver is low down. Case 37 shows the position of the parts when they are raised up by distended intestines below. Case 38 shows how the pylorus is not displaced downwards to any material extent when the stomach alone is low down. The scale represents centimetres.

before it the projecting anterior border of the pancreas and the transverse meso-colon.

THE INFLUENCE OF THE STOMACH UPON THE SHAPE AND POSITION OF THE PARTS BEHIND IT.[3]

The parts behind the stomach in the hardened specimen or in a good fresh subject present a well-marked and regular concavity for the reception of the cardiac portion of the stomach which Birmingham[4] aptly described as the stomach-bed. When the stomach is removed the convexity of the central part of the diaphragm downwards, produced by the heart, is seen. Passing to the left, this convexity passes into the concavity which lodges the summit of the stomach and which projects, as a rule, one centimetre higher than the highest point of the spleen. This concavity, continued either from above downwards or from the left inwards, passes into the hollow of the gastric surface of the spleen which forms the completion of the outer wall and a part of the floor of a deep concavity which projects backwards to a plane up to six centimetres posterior to the front of the aorta and the pancreas in the middle line. The floor of this concavity, traced inwards, is completed below the innermost part of the spleen by a portion of the anterior surface of the left kidney at its upper part, then by a varying part of the left suprarenal body with the adjoining left semilunar ganglion, and finally by the left crus of the diaphragm as it overlies the vertebral bodies. Traced downwards, the floor of the concavity passes on to the gastric surface of the pancreas, which, sloping more or less forwards, completes the support of the stomach behind and leads on to the transverse meso-colon, which, passing from the anterior border of the pancreas and being itself supported inferiorly by the small intestines, completes, with the projecting portion of the pancreas behind and the splenic flexure of the colon at the left, the support of the stomach below. The extent of the gastric surface of the left suprarenal capsule is determined partly by the position of the convolutions of the splenic artery, which often quite overlap it, partly by the size of the spleen and pancreas, and partly by the position of the pancreas. When the pancreas is pushed upwards by the intestines below, or downwards by the stomach above, it sometimes carries the suprarenal body with it to a certain extent. Moreover, when the upper part of the spleen is enlarged it may spread downwards over the gastric surface of the left suprarenal, as well as over that of the adjoining kidney, and shut them out from direct relation with the stomach. That which we have called the anterior border of the pancreas becomes, when it is traced inwards to the middle line, the lower border of the body of the gland and overhangs the emergence of the mesenteric vessels. It represents at this place the conjoined anterior and posterior borders, the inferior surface having ceased. However, even in the middle line it will be convenient still to speak of this border as the anterior.

We have just said that the stomach, resting on its bed, is supported at its lower part on the gastric surface of the pancreas which, sloping downwards and forwards to its anterior border, forms in varying degrees a supporting shelf for the stomach. When the stomach is lowly situated it tends to press down the anterior border of the pancreas, to increase the vertical depth of its gastric surface and to diminish the depth antero-posteriorly of its inferior surface; that is, to flatten out the pancreas. This process is accompanied by a pushing down of the pancreas over the face of the left kidney; thus giving the kidney an increased gastric surface. In its descent the pancreas occasionally drags down the left suprarenal body with it to some extent. Finally, the descent of the stomach is not accompanied by a descent of the left kidney. The reverse of these processes takes place when the stomach is raised up by distended intestines; the depth on a vertical plane of the gastric surface of the pancreas is diminished, whilst that of its inferior surface is increased antero-posteriorly, its anterior border becomes more prominent, and the gland, being pushed upwards, tends to obliterate the gastric surface of the left kidney. Fig. 6 is designed to illustrate these points; but a detailed comparison of the outlines of the whole series, which are before you, on the reduced scale of the stomach with those of the duodenum and adjoining viscera brings out the points more fully.

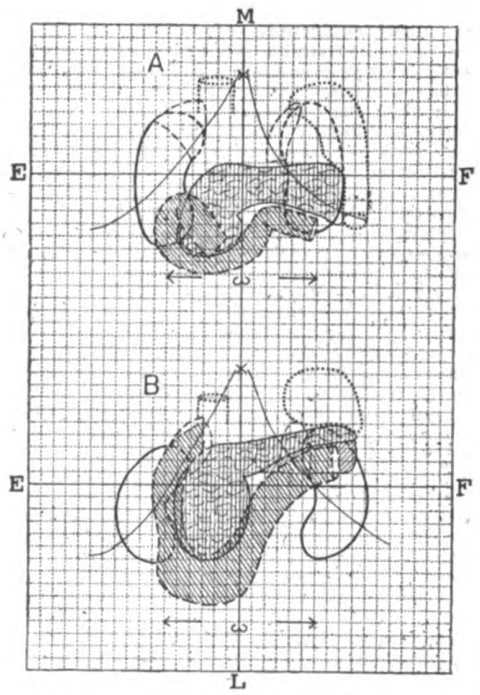
[3] Compare the stomach and liver outlines from Cases 36 and 37 on Figs. 5A and 5B with the outlines of the deeper viscera from the same cases on Fig 6.

[4] The Topographical Anatomy of the Spleen, &c., Journal of Anatomy and Physiology, vol. xxxi., 1896.

Take two adjoining contrast cases—viz., Cases 36 and 37. In Case 36, as Fig. 5A shows, there was a low stomach. Fig. 6 therefore shows a flat pancreas—that is, one having a large gastric and a small inferior surface—and, moreover, this flat pancreas is seen to be low down on the left kidney, leaving a large gastric surface of the kidney exposed above it. In Case 37, on the contrary, the illustrations show the conditions to be reversed: a high stomach, a pancreas with a large inferior and a small gastric surface—pushed up, that is, from below so much that the kidney has no gastric surface at all.

The ridge presented by the pancreas over the front of the vertebral column was, when present, usually found to the left of the middle line, having a direction downwards and

FIG. 6.



Outline A shows the position of the parts behind the stomach from Case 36 as an example of the displacements when the liver and stomach are low down. Outline B shows the same parts when the stomach and liver are high up (from Case 37, see text). The scale represents centimetres. M, L, The middle line. inwards and corresponding to the groove often present on the overlying part of the stomach. The pancreas projected in the average 0·5 centimetre above the lesser curvature in the middle line.

Professor J. Symington,[5] speaking of the omental tuberosity which the pancreas sometimes presents as it projects above the lesser curvature of the stomach, says: "As a rule I believe it will be found much more distinct when the stomach is distended than when it is empty." In these cases it was very distinct either as a ridge or tubercle in seven instances. In all of these the stomach was described either as well filled or distended and in all cases except one it was low down. When the stomach was fairly high in the abdomen, although distended, the omental tuberosity was noted either as very small or practically absent. Apparently a large omental tuberosity of the pancreas occurs when the stomach is low down and distended, as distinguished from those cases in which, whilst distended, it maintains its normal level.

THE DUODENUM.

The general surface marking of the duodenum has already been given. The first three parts of the duodenum are moulded around the head of the pancreas and the second part

[5] On the Topographical Anatomy of the Pancreas, Transactions of the Royal Academy of Medicine of Ireland, vol. xiii., 1896.

especially lies in a deep groove along its right border. In none of the cases in this series were the lips of the groove sufficiently voluminous to encircle this part of the duodenum, although in most cases the posterior lip of the groove extended sufficiently behind the duodenum to prevent its coming into immediate relation with the inferior vena cava. In the average the bend between the first and second parts the duodenum overlies the lower angle of the right suprarenal body. 13 of the cases, or 32·5 per cent., illustrate the fact that the duodenum often passes to a considerable extent on a sagittal plane, so that when the highest point of the first part of the duodenum is described as being only two centimetres further outwards than the pylorus it does not necessarily indicate that the first part of the duodenum is only two centimetres long, for, as in these cases, it may have passed almost directly backwards. The lower border of the liver usually overlaps the highest part of the duodenum for three and a half centimetres. In the average the *gall-bladder* projected on to the front lies in the right lateral line with its tip directly in front of, and nearly half way down, the second part of the duodenum. The lower part of the gall-bladder is usually lifted off the duodenum by the transverse colon, but in the average it directly overlies the duodenum at the intersection of the upper transverse abdominal line (E, F)[6] and the right lateral line. The nearness of the lowest part of the duodenum to the highest part of the iliac crest has been already pointed out, and when that bone can conveniently be felt it constitutes a useful guide to that part of the bowel.

Variations in the position of the duodenum.—The highest point of the duodenum (usually where the first part bends down to become the second part) averaged 1·8 centimetres above E, F (Fig. 3, Lecture I.). There were 30 cases in which it did not vary more than two centimetres from the average one way or the other, calling the average two centimetres above E, F. There were five cases more than four centimetres up to 6·5 centimetres above E, F, which we will call those of high level; and five cases lower than E, F, up to 4·5 centimetres below, and these we will call those of low level.

1. *High level.*—All these cases were amongst those that have been already noticed, in which the stomach and the lower border of the liver were at a high level and were, for the most part, pushed up by distended intestines, specially by the transverse colon.

2. *Low level.*—All these were cases in which the stomach was distended and with the liver reached low down in the abdomen.

3. There is a third group of cases in which the stomach was low down and distended but in which the liver maintained its normal level. In these cases we find the duodenum was at its normal level, being held up, as we have previously described, with the pylorus to the under surface of the liver by the strong right part of the lesser omentum.

It becomes evident, on comparing these three groups of cases, that lowering, or increase in size downwards, of the liver is the chief determining agent in depressing the first part of the duodenum, as it is that of the pylorus; and that distension of the stomach alone is not sufficient to produce this effect. Further, it appears that the causes that push up the liver and stomach also push up the first part of the duodenum.

Cysto-colic fold.—Sometimes the peritoneum is prolonged further to the right than the usual position of the right border of the lesser omentum and extends from the transverse fissure of the liver along the under surface of the gall-bladder superiorly, and along the upper border of the duodenum inferiorly, on to the hepatic flexure of the colon, and forms at this place a fold stretching from the gall-bladder to the colon presenting a free border directed more or less to the right. This cysto-colic fold, representing a prolongation of the lesser omentum to the right, was present in 12 cases, or 30 per cent.

The duodenum and the right kidney.—Professor D. J. Cunningham in his "Practical Anatomy,"[7] speaking of the relative levels of the duodenum and the right kidney, says: "The duodenum, moulded as it is on the vertebral column and around the head of the pancreas, is not subject to much variation in position. The differences seen in the figure are probably due to variations in the positions of the kidney." The cases in this series do not support this statement. The duodenum is subject to considerable movements in position in regard to the vertebral column. For instance, between Cases 5 and 7 of this series the difference in level of the upper border of the first part of the duodenum compared with the disc between the first and second lumbar vertebræ was 9·5 centimetres, or nearly four inches—viz., from 5·5 centimetres above in Case 5 to four centimetres below in Case 7. The upper border of the right kidney fell in the same cases only 4·5 centimetres—viz., from 6·5 centimetres above in Case 5 to two centimetres above in Case 7. On Fig. 7 these variations are set out in detail on the two curves; in the upper one A the positions of the highest point of the duodenum and of the upper pole of the right kidney are shown about the line E, F, and in the lower curve B about the first lumbar inter-vertebral disc. It is quite evident from these that the duodenum is quite as variable in its level in relation to the vertebral column as the upper pole of the right kidney is, if anything, more so.

We are not concerned in this place with the causes which produce alterations in the level of the right kidney; but it can be said that as far as the cases go they do not enable us to say in any one case, when the relative levels of the duodenum and right kidney are unusual, that the difference is produced by an alteration in the position of the kidney, or even chiefly so. *If the liver be enlarged and lower than usual it is most likely to be the duodenum that is displaced downwards;* and if the liver and stomach be raised up by distended intestines it is very likely that the duodenum also will be pushed up to some extent.

I need not detain you to analyse the lateral variations of the duodenum. In five cases the highest point of the duodenum was either on the middle line or as little as one centimetre to the right of it. An examination of the cases shows that the conditions associated with these displacements run practically parallel with those already described in considering the lateral displacements of the pylorus. In 40 per cent. of the cases the lowest part of the duodenum was at or below the highest point of the iliac crest and in 60 per cent. above it. The duodenum over the middle line is subject in some measure to the various displacing forces that have already been considered. Its lower border averaged 2·3 centimetres above the umbilicus. In 29 cases (72·5 per cent.) it was from one to five centimetres above, inclusive, but in the rest of the cases it varied from 6·5 centimetres above to four centimetres below.

The duodeno-jejunal flexure.—The duodeno-jejunal flexure is held up beneath the inferior surface of the pancreas by the fibrous tissue surrounding the mesenteric vessels and coming down from the diaphragm on to and over the flexure. The overlapping part of the pancreas, situated on the vertebral column just to the left of the middle line, is the least moveable part of the gland, the tail at the left being more freely moved by a distended stomach and the head of the pancreas at the right, along with the duodenum, being more directly exposed to the displacing force of an enlarged liver, as we have seen. Mr. C. B. Lockwood[8] takes the upper border of the duodeno-jejunal flexure to represent the upper border of the mesentery There were 30 cases, or 75 per cent., of this series in which the upper border of the duodeno-jejunal flexure was not situated more than two centimetres away from E, F, one way or the other. There were three cases more than two up to four centimetres above E, F, and in all of these the stomach was highly situated, being mostly pushed up by distended intestines. There were four cases three centimetres or more up to six centimetres below E, F, and in all of these the stomach was distended and, together with the liver, occupied a low position. There were, however, three other cases in which, whilst the stomach was low down and more or less distended, the duodeno-jejunal flexure was not lower than usual. The plates of these cases show that the liver, though low down, did not directly press on the flexure.

If we contrast these variations with those of the other parts of the duodenum we may fairly say that *the duodeno-jejunal flexure is the most stable part of the duodenum and that a distended stomach, in the absence of an enlarged or downwardly displaced liver, is not sufficient to cause its material downward displacement.*

Shape of the duodenum.—The first and fourth parts of the duodenum are those most subject to variation in shape:

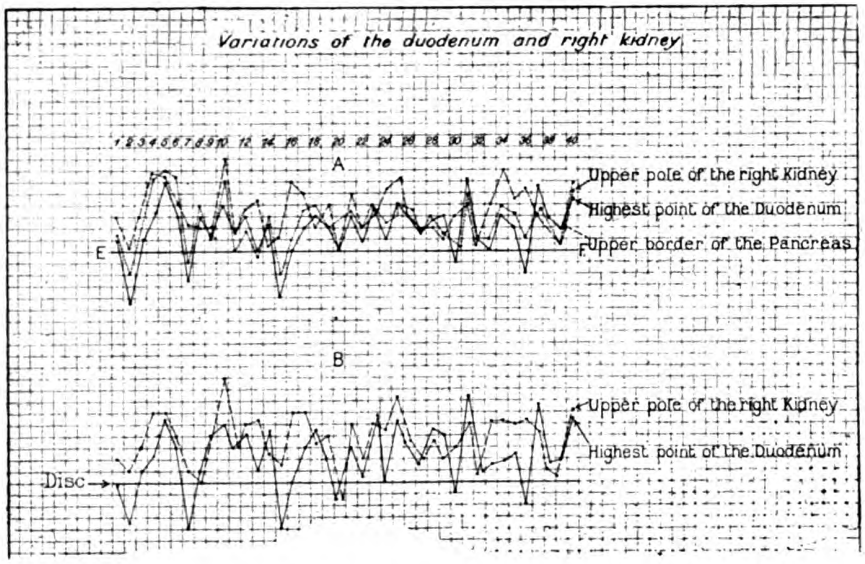
[6] Readers are reminded that this line which, for convenience, is called E, F, is drawn transversely across the abdomen through a point half-way from the upper border of the pubes to the supra-sternal notch.

[7] Vol. i., p. 492.

[8] Lectures on Hernia, London, 1889.

the first from displacements; the fourth from abnormalities, chiefly connected with its special position in regard to the peritoneal folds in its neighbourhood. Time does not permit more than to draw your attention to the special cases. In Case 7 the duodenum (which will be illustrated in the next lecture) was pushed downwards and to the left by the liver; the lower left portion of the head of the pancreas, which is sometimes spoken of as the lesser pancreas, extended across the fourth part of the duodenum into the root of the mesentery. The mesenteric vessels passed in front of this lesser pancreas into the root of the mesentery as usual and the fourth or ascending part of the duodenum was situated to the right of the middle line. The condition can hardly be accounted for by the displacement, and it most likely represents a duodenum with a simple bend like that of the bonnet monkey (Treves[9]). Four cases presented an abnormality in which, after the usual position of the duodeno-jejunal flexure was reached, there was an additional bend towards or across the middle line. In all these cases, as far as the point represented in the illustrations, this

FIG. 7.



A, shows the variations in the position of the upper pole of the right kidney, the highest point of the duodenum, and the upper border of the pancreas in regard to the upper transverse abdominal line E, F. B, shows the variations in the position of the upper pole of the right kidney and the highest point of the duodenum in regard to the disc between the first and second lumbar vertebræ. The scale represents centimetres.

additional part of the duodenum was firmly bound down by the peritoneum.

THE SMALL INTESTINES.

It would seem, according to the recent researches of Mall,[10] that the intestines, even after disturbance, shaking or even manipulation, do in a general way fall back again into their previous position and seem to preserve in an individual a certain uniformity in the plan of their arrangement. The investigation of the general or relative position of the various coils of the small intestine is, and must remain a matter of much difficulty. Although it may not be difficult in the infant, in a good proportion of cases, to point to some general plan in their arrangement, yet, with the changes in diet, the increase in length of the intestines, and the manifold displacing influences to which they are exposed in the adult, it is not easy to consider that the arrangement in the infant, even if shown to be fairly regular, establishes anything but a low probability as to the nature of the arrangement likely to be met with in the adult. The intestines move most freely in the upper left lateral and the central regions of the abdomen. Taking the general direction of the mesentery from above downwards, from left to right, the coils in the left upper region are mostly jejunum and those in the right lower region chiefly ileum. The left upon the mesentery, and the upper end or direction of the root of the portion of mesentery with its attached bowel is found, either the part near the thumb or towards the little finger, as the case may be.

THE PERITONEUM.

Prolapse of the mesentery.—The upper border of the duodeno-jejunal flexure represents the upper border of the root of the mesentery, so that what we have said of displacements of the former applies equally to the latter. Mr. Lockwood[15] in his work gives the upper border of the mesentery as from three to four inches above a base line drawn across the highest parts of the iliac crests. The average obtained from these cases of 9·5 centimetres above the iliac crest agrees very well with Mr. Lockwood's measurements in adults up to 40 years of age. He considers that when the distance is less than three inches (say, seven centimetres or less) the mesentery may be termed prolapsed. He associates prolapse of the mesentery especially with prolapse of the splenic flexure of the colon. We have seen that a low position of the liver and stomach are specially associated with a low position of the duodeno-jejuna[l]

[15] Op. cit.

flexure, and we should not expect that an enlarged or downwardly displaced liver would operate, in the absence of special laxity of the peritoneal bands or of the abdominal muscles, in so direct a manner on the splenic flexure of the colon. In six cases of this series the mesentery was prolapsed according to Mr. Lockwood's definition. In all of them there was a large or low liver with a distended stomach. In four of them the splenic flexure of the colon was prolapsed, whilst in the remaining two it was not. On the other hand, there were eight cases presenting prolapse of the splenic flexure of the colon, in four of which the mesentery was prolapsed, and in two others it was only just above the line of prolapse. In all of these cases the low position of the liver and stomach was noted, and in the remaining two cases the splenic flexure was prolapsed without the other conditions. In those cases in which the mesentery was prolapsed without the splenic flexure of the colon the costo-colic ligament was found strong and held up the colon in spite of the low liver and stomach. In those cases in which the splenic flexure of the colon was prolapsed, without the prolapsed mesentery and the accompanying conditions, the costo-colic ligament was very thin or badly marked. *We may say, therefore,* that whilst, as Mr. Lockwood remarks, prolapse of the splenic flexure of the colon and of the mesentery are commonly associated, the latter is chiefly related to the position of the liver and stomach; the former, in addition to these circumstances, possesses as a separate determining factor the strength of the costo-colic ligament.

The ages of the patients presenting one or both of these conditions were over 40 years in all but three instances and in two of these the ages were 36 and 39 years respectively. In the other case, that of a lad, aged 13 years, the whole of the viscera in the upper part of the abdomen were displaced downwards by an enormous intra-thoracic growth. The root of the mesentery crossed the middle line low down in eight cases, ranging from 10 to 14·5 centimetres below E, F, and allowed the intestines in the left abdominal quarter a freer range of movement. In all but two of them there was a low transverse colon; in all but three of them the stomach was low down; but only in three of them, however, was the root of the mesentery anything prolapsed at its upper end. In all but two cases the patients were more than 45 years of age. In one of the cases there was a left inguinal hernia consisting only of a portion of the sigmoid flexure of the colon.

The attachment of the *lower end* of the mesentery in these cases was 8·5 centimetres directly above Poupart's ligament. This agrees very well with Mr. Lockwood's figures when it is remembered that in these measurements Poupart's ligament is considered as stretching in a straight line from the anterior superior iliac spine to the spine of the pubes. Mr. Lockwood speaks of the lower end of the mesentery as prolapsed or dragged down when it is less than two and a half inches, or 6·25 centimetres, above Poupart's ligament. The four cases in which this condition existed in this series presented nothing in common except a low position of the hepatic loop downwards of the transverse colon.

THE LOWER END OF THE ILEUM.

The lower end of the ileum occupies a fairly constant position over the right psoas muscle a little below where it comes to form the right pelvic brim. It is nearly always directed upwards and outwards, and the mesentery, where the ileum overlies the psoas, usually shortens somewhat abruptly, allowing the terminal part of the bowel only a limited range of movement. The attachment of the lower end of the ileum is often made firmer by a prominent peritoneal fold—the plica vascularis—which passes downwards from beneath the ileum as it overlies the inner border of the psoas to the middle of Poupart's ligament. Sometimes this part of the bowel is firmly bound down to the iliac fossa, whilst in other cases it lies in the pelvic cavity with a prolapsed cæcum. These positions and mobilities of the lower end of the ileum from the 40 cases may be thus summarised. In eight cases, or 20 per cent., it was firmly fixed in the iliac fossa. In 12 cases, or 30 per cent., it had a limited range of mobility. In 20 cases, or 50 per cent., it was freely moveable in various positions. In four of the freely moveable cases the lower end of the ileum was wholly within the pelvic cavity with a prolapsed cæcum.

A Lecture
ON
SOME RECENT DEVELOPMENTS IN THE ADMINISTRATION OF ANÆSTHETICS.

BY FREDERIC W. HEWITT, M.A., M.D. CANTAB.,
ANÆSTHETIST AND INSTRUCTOR IN ANÆSTHETICS AT THE LONDON HOSPITAL; ANÆSTHETIST AT THE DENTAL HOSPITAL OF LONDON.

GENTLEMEN,—In every department of practical medicine progress is, as you are aware, constantly taking place; and although it cannot be said that the latter half of the century which has just drawn to a close has been conspicuous for any great discoveries in the branch of therapeutics to which I would now direct your attention, it cannot, I think, be denied that very important developments have during that time been effected in the various methods of inducing and maintaining anæsthesia. With most of these improvements you are doubtless familiar, but there are some which, by reason of their comparatively recent introduction into practice, may not have attracted your attention.

Of all the known systems of inducing anæsthesia there can be no doubt that that introduced many years ago by Clover is the best. I refer to the system of administering nitrous oxide and ether in succession. The advantages of this plan are that the initial sensations experienced by the patient are not unpleasant, that consciousness is rapidly destroyed, and that the stage of struggling and excitement is in the vast majority of cases wholly eliminated. The system is, moreover, a remarkably safe one, provided that the anæsthetist has had some little experience in its application. It is a mistake, however, to suppose that any system of inducing anæsthesia can be made perfectly safe, and it thus happens that even with this nitrous oxide-ether sequence cases occasionally present themselves in which alarming or possibly fatal symptoms arise.

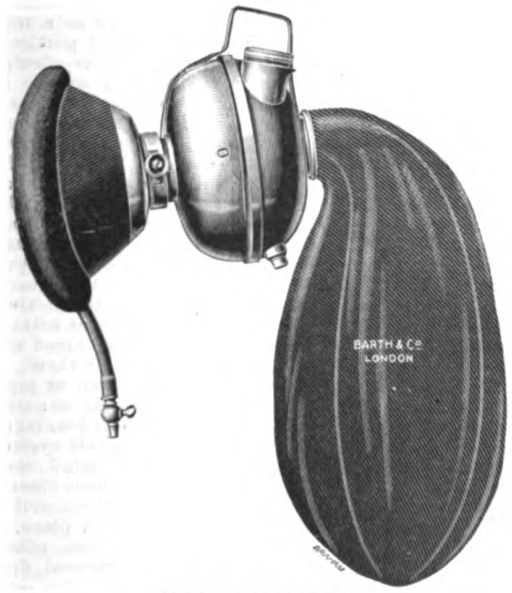
Clover's system of inducing anæsthesia by means of nitrous oxide and ether may be applied in a variety of ways which may be appropriately spoken of as methods, but time will not allow of my describing these methods to you in detail. I have given them one and all a thorough trial, and although I cannot on the present occasion pause to give you my reasons I may tell you that in one respect or another each of the recognised methods of administering nitrous oxide and ether in succession has failed to satisfy me. In some of them there is a sudden transition from the one anæsthetic to the other, with the result that, in certain subjects, asphyxial difficulties arise and very quickly and seriously complicate the administration. In others, although the anæsthetics are gradually mixed, the channels of the inhaler through which the patient breathes are so circuitous and narrow that an unpleasant and undesirable stress is thrown upon respiration. In others, again, delay is caused by measuring out doses of ether, the patient is distressed by the rushing noise of the nitrous oxide, whilst the too familiar odour of the other anæsthetic is not wholly prevented. Or, finally, the apparatus employed cannot be thoroughly cleansed after each administration.

I have accordingly been endeavouring during the past few years to devise a method of administering "gas and ether" which would be free from the objections to which I have alluded. But before I describe this in detail I must ask your attention to a few interesting considerations in regard to the asphyxial factor in the administration of ether by means of so-called close inhalers. Perhaps the most important of the lessons taught us by Clover was that by permitting a certain degree of re-breathing during etherisation it is possible to produce a very powerful effect—an effect, indeed, which serves to render ether almost as potent and as manageable as chloroform. Re-breathing a limited supply of air has, as you are aware, a double result: it leads to a diminished ingress of oxygen—i.e., to anoxæmia—and to a retardation in the elimination of carbonic acid. Now, this result contributes very considerably to the anæsthesia. There are, in fact, by

Clover's system of etherisation, two factors brought into play which may for purposes of description be termed the ether factor and the asphyxial factor. Each is complementary to the other. The more the ether factor is used the less need will there be for the asphyxial; the more the asphyxial element is employed the less need will there be for the ether element. Now, Clover, as you may be aware, utilised the asphyxial factor very largely, as is obvious from the directions which he gave for the use of his inhalers. He paid but little attention to the patient's colour; he kept up a semi-asphyxial state; he used comparatively little ether. His inhalers, moreover, were constructed with remarkably narrow channels, but whether such a plan of construction was by accident or design I cannot say. It is highly probable that Clover, who was conspicuous for his ingenuity, was aware of the influence which these narrow bores themselves exerted upon the respiratory system of the patient and upon the phenomena of anæsthesia. So far as I am aware, however, there is no record of his views on these points. We only know that his "gas and ether" inhaler and his ether inhaler are remarkably powerful in their effects, and that, as I shall now indicate to you, these effects are to no small extent dependent upon the narrow channels through which the patient breathes.

In order to satisfy myself as to the precise influences exerted by the calibre or bore of an ether inhaler I had constructed for me by Messrs. Barth and Co. (to whom I am greatly indebted) several inhalers of different bores.[1] The inhaler I now show you (Fig. 1) has, as you see, a very wide

FIG. 1.



Large-bore ether inhaler.

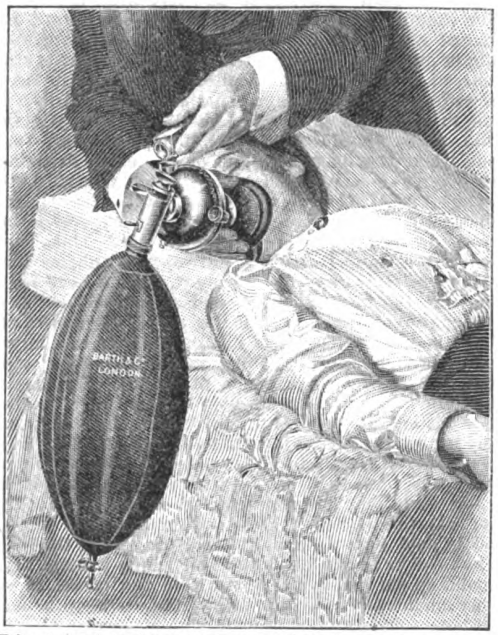
bore, but it is in its other main features similar to Clover's regulating ether inhaler. Its face-piece is, however, differently fixed; it is screwed into the ether reservoir so that it cannot become unexpectedly detached; and the air-current is admitted to the ether reservoir not by rotating the latter but by moving a regulating handle. The face-piece can be fixed to the ether reservoir at any desired angle (by means of a little screw) so that the filling tube of the reservoir remains with its mouth uppermost for re-filling. Now, when this inhaler is used for administering nitrous oxide and ether in succession—for which succession it is specially intended—there is, by reason of its wide bore, a distinct alteration in the usual phenomena of a "gas and ether" administration. The principal difference is that stertor and cyanosis are lessened and that the patient passes smoothly, with little or no respiratory derangement, from the anæsthesia of nitrous oxide to that of ether. The interesting question naturally arises, How is it that this enlargement of bore eliminates to such an extent the usual stertor and cyanosis of the succession of anæsthetics now under consideration? One can understand constricted channels causing distress at the very outset of an administration and a state of hyperpnœa throughout the administration. But why the stertor and cyanosis? If we can explain the former we can, of course, readily understand the latter, for any tendency towards occlusion of the air-tract, such as that which stertor always indicates, would necessarily limit the ingress of oxygen and so cause duskiness of the features. Now, there appear to me to be two possible explanations of the stertor caused by narrow-bore inhalers, but both are, I fear, somewhat hypothetical. Little is definitely known as to the physiology of stertor, but, so far as it arises under anæsthetics, it seems to me that it may become established in one of three distinct ways. It may either be (1) vascular, (2) spasmodic, or (3) paralytic in its nature. In vascular stertor certain parts of the air-passages become swollen by reason of vascular turgescence and so narrow the air-way—as, for example, when the tongue becomes engorged in the course of asphyxia. In spasmodic stertor certain muscles within or about the upper air-tract are thrown into a state of spasm, so that the normal calibre of the tract becomes narrowed—as, for example, when the tongue is drawn backwards to meet the pharyngéal wall. In paralytic stertor certain parts of the air-way fall together—as, for example, when the flaccid tongue of a deeply anæsthetised patient lying in the dorsal posture gravitates towards the pharyngeal wall. Now, it is quite conceivable that the stertor produced by narrow-bore ether inhalers may be either of the vascular or of the spasmodic variety. Thus, when a patient is breathing through a narrow-bore inhaler there is during each *inspiration* a tendency towards a negative pressure within the upper air-tract, and as a result of this more or less continuous tendency, an increased vascularity of the soft parts—the tongue, soft palate, pharynx, and laryngeal folds—is brought about, leading to a swelling and approximation of these parts and hence to stertor. You may often observe the tongue greatly swollen during "close" etherisation or during any administration, indeed, in which the air-supply is accidentally or intentionally restricted at the nasal or oral orifices. But I also have notes of cases in which the stertor has seemed to be of the spasmodic rather than of the vascular variety. The sequence of events has apparently been: (1) diminished ingress of oxygen and egress of carbonic acid by reason of the narrow bore of the inhaler; (2) an asphyxial state of the blood; (3) general or local muscular spasm (asphyxial spasm); in the course of which (4) spasmodic stertor arises. Now, the stertor produced by small-bore inhalers may become very inconvenient, if not dangerous, in persons of certain types. For example, it would be wrong practice to anæsthetise by means of a Clover's inhaler a patient suffering from angina Ludovici. In actual practice you will find that spasmodic stertor may in certain subjects become associated with, or replaced by, vascular stertor, and *vice versâ*. One of the most anxious cases I ever had to anæsthetise taught me this fact. The patient's naturally narrow air-passages favoured the occurrence of spasmodic stertor, and after the latter had existed for a few moments all parts of the throat became so engorged by venous blood that it was impossible to pass even the tip of one's finger beyond the enormously swelled fauces. Fortunately laryngotomy and forced inflation of the lungs saved the patient. Now, these facts, although they have only an indirect bearing upon the point immediately under discussion—the narrow bores of inhalers—will show you how important it is to avoid all asphyxial methods in certain subjects and to look with suspicion upon deep and obstructive stertor whenever it may arise.

In addition to the large-bore inhaler which I now have the pleasure of introducing to your notice preventing respiratory embarrassment during the induction of gas and ether anæsthesia, it obviates the other main objection which seems to me to be attached to the plan of adapting a gas-bag to a Clover's ether inhaler—viz., the possibility of there being a slight odour of ether at the commencement of the administration. By the usual plan of procedure a measured quantity of ether is first poured into the ether reservoir, and although it is possible for an experienced anæsthetist to completely, or almost completely, prevent his patient detecting any odour of ether, any shaking or rough usage of the charged inhaler may lead to an escape of vapour when the face-piece is applied. Now, by having a fixed ether reservoir it is possible to *introduce the ether when*

[1] Messrs. Barth and Co., of 54, Poland-street, Oxford-street, W., are the sole makers of this apparatus.

the patient is partly anæsthetised by nitrous oxide. (See Fig. 2.) The administration of nitrous oxide and ether in succession is thus conducted:—1. A face-piece of appropriate size having been fixed to the ether reservoir, the latter is, in cold weather, partly immersed in hot water for a few moments; the indicating handle is placed at "O" and the plug of the filling-tube is removed. 2. A two-gallon gas-bag partly full of nitrous oxide (the amount varying with the type of subject) is fitted to the reservoir. 3. The patient is instructed to breathe freely backwards and forwards through the mouth, and air will enter and leave the lungs through the valves in the gas-bag stop-cock. 4. Nitrous oxide is now turned on, and after two or three expirations have escaped at the expiratory valve the valve action is stopped and the remaining quantity of nitrous oxide is breathed backwards and forwards.

FIG. 2.



Ether being introduced during the inhalation of nitrous oxide.

5. Immediately this has been done about from one and a half to two ounces of ether are rapidly introduced through the wide and open filling-tube and the plug is replaced (Fig. 2). It is important that the face-piece should accurately fit the face during these procedures. 6. The regulating handle is now progressively moved from "O" to "¼," "½," "¾," or "Full," these markings indicating the proportions of the current thrown over ether. 7. At the end of about one minute, or possibly earlier in some cases, a breath of air is admitted at the stop-cock of the gas-bag. 8. At the end of about one and a half minutes the gas-bag is replaced by a smaller bag (Fig. 1) and the administration is thenceforward conducted as with Clover's inhaler, the regulating handle being kept at that point which seems suitable to the particular case. You will observe that whatever posture the patient be placed in (except the dorsal with the face looking upwards, a posture which is not to be recommended for inducing anæsthesia) the ether reservoir may be so adjusted to the face-piece that the opening through which the ether is poured in can be used without removing the apparatus from the patient. A glass "window" in the plug of the filling-tube is of service as indicating the quantity of ether in the inhaler. I have used this apparatus for upwards of a year in private practice and this fact warrants me in bringing it before your notice. It is only right, however, that I should tell you that I have had practically no experience with it for administering ether *per se*, for I never employ this plan except in hospital practice, and when I have been engaged in my demonstrations here I have felt myself bound to employ the inhalers commonly in use.

I would now draw your attention to what may be termed the gas-ether-chloroform sequence, by which I mean the successive administration of these three anæsthetics to the same patient. You are all aware that when ether is "taken badly," as the expression goes, it is more or less customary to substitute chloroform, but it is not with cases of this kind that I am now concerned. I would rather direct your attention to what may be called the routine use of the gas-ether-chloroform sequence. By this system of anæsthetisation anæsthesia is induced by "gas and ether" and maintained by chloroform. Loosely speaking, we may say—"gas" for the patient, ether for the anæsthetist, and chloroform for the surgeon. Nitrous oxide is advantageous to the patient for reasons which I have already given you; ether is advantageous to the anæsthetist because of its great safety and stimulant action upon the patient's respiration and circulation; and chloroform is advantageous to the surgeon because of the comparative quietude of the patient and the comparative freedom from venous engorgement and hæmorrhage during the administration. There are, however, numerous other advantages in this system. I have often pointed out to you that the principal risk of chloroform is the risk which is incurred during the second stage of anæsthetisation—a stage which in certain subjects is characterised by excitement, rigidity, and struggling. Now by the sequence under consideration this risk is wholly eliminated, for the struggling stage is passed over whilst the patient is under nitrous oxide and ether, with which anæsthetics there is, practically speaking, no such risk. It is therefore clear that by the nitrous oxide-ether-chloroform sequence we are able to obtain the advantages of chloroform without at the same time experiencing one of its chief disadvantages. But there is something more. One of the chief objections to ether as a routine anæsthetic is that after its administration, and particularly after its prolonged administration, certain after-effects are not uncommon. I refer more particularly to the taste and smell of ether experienced by the patient, to nausea and vomiting, and to bronchial and pulmonary sequelæ. Now, by the nitrous oxide-ether-chloroform sequence these disadvantages of ether are largely or wholly eliminated; for the quantity of ether vapour inhaled, although sufficient to impart to the administration characters such as it could never otherwise acquire, is insufficient to prejudicially affect the recovery-period. The return to normal consciousness, indeed, is altogether more satisfactory than after ether alone. Possibly the absence of that wear and tear of nervous machinery which must attend the protracted inhalation of ether may help to account to some extent for these happy results; or the greater economy of blood which marks the use of chloroform may help to explain them. But of this I am convinced, that there is no plan at present known of inducing and maintaining surgical anæsthesia which has so many advantages and so few disadvantages as the one which I now describe. In applying this system of anæsthetisation you must, however, bear in mind certain points; for if the sequence be attempted without observing certain cardinal principles you may easily find yourself face to face with alarming symptoms. In the first place, you should, for reasons just given, never change from ether to chloroform whilst a patient is struggling. Several deaths have thus occurred. In the next place, you must be careful never to effect the change unless there is at the moment of such change some evidence that the patient is not profoundly anæsthetised by ether. Thus it is a good plan in employing the sequence to administer ether till the corneal reflex has just disappeared, to remove the ether inhaler for a few breaths of air, to allow a slight cough to occur in order to free the larynx of any mucus that may have entered it, to watch for the first indication of returning corneal reflex, and then to begin the chloroform inhalation. It is particularly important in the case of abdominal operations that a cough should be allowed before the chloroform is begun, for if the chloroformisation be started whilst the larynx contains mucus considerable respiratory difficulty may arise. It is in this way that high-pitched laryngeal stridor, cyanosis, exaggerated diaphragmatic action, and abdominal rigidity may often come about. It is also important in abdominal cases to effect the change from ether to chloroform before the operation is begun, for as this change should only be made during a comparatively light anæsthesia, and as this anæsthesia may be associated with rigidity or movement, much inconvenience to the surgeon may be caused by changing when the operation is in progress. In the

next place, as regards the depth of chloroform anæsthesia which should be maintained, I find that when once patients have been placed well under ether and have then been allowed to clear the larynx, it is not necessary to subsequently maintain a very profound chloroform narcosis—in other words, by educating the tactile sensibility of one's finger it is generally possible to allow a very slight trace of lid reflex save perhaps in abdominal cases. If, however, the change from ether to chloroform be effected without the larynx having cleared itself the mucus present in this organ may persistently tend to excite local and even distant spasmodic states, with the result that, in his endeavours to suppress the inconvenient phenomena the anæsthetist may readily administer a dangerously large dose of chloroform. The presence of viscid mucus within the larynx rarely if ever leads to occlusion of the air-tract during the administration of ether, probably because the force of the respiratory current under this anæsthetic is sufficiently great to keep the fluid in a state of active movement. But I have notes of two cases which occurred some time ago, before I had become aware of the importance of proceeding as I have described, in which during a deep chloroform anæsthesia, whilst the breathing was somewhat shallow, the presence of ether-mucus within the larynx apparently acted as the "last straw" and arrested breathing. Simple chest compression quickly dislodged the mucus and restored respiration.

The nitrous oxide-ether-chloroform sequence is particularly appropriate in the surgery of the mouth, throat, and nose.

FIG. 3.

Modified Junker's inhaler.

As a general rule it is advisable for these operations to place the patient well under ether, to insert the gag and any necessary appliance for maintaining anæsthesia, and then to allow the slight recovery to which I have alluded. From this moment onwards anæsthesia is kept up by means of a Junker's inhaler. Messrs. Krohne and Sesemann have recently constructed for me the modification which I now show you (Fig. 3). In addition to its being so made that no mistake can occur in adjusting the wrong indiarubber tubes upon the mounts of the bottle, you will observe that the apparatus is provided with a metal stop-cock which when turned converts the chloroform receptacle into a stopper-tight bottle which can be packed away in a bag without removing the chloroform. There are also other little improvements which hardly deserve special notice.

The last development in anæsthetisation to which I shall refer is a plan of maintaining chloroform anæsthesia during certain nasal and oral operations. It is customary, whenever the surgeon desires to keep the mouth of the patient more or less widely open, to insert a Mason's gag between the teeth or to employ some similar plan. Now this gag, as well as most others of its type, has the effect of stretching the lips and distorting the anterior nasal orifice of that side on which the gag is inserted. The inconvenience to the surgeon thus occasioned is particularly felt in antral and nasal operations, and it is for such operations that I have devised the little appliance which I now show you. It is made by Messrs. Krohne and Sesemann and may be termed a "chloroform-prop" (Fig. 4). It consists of a solid wedge-shaped metal

FIG. 4.

The chloroform-prop.

prop which can be inserted in wedge fashion between the molar teeth. It has side flanges to prevent lateral displacement, and the parts of the prop which come against the teeth are made of lead to allow of the prop being gripped when in position. A bent metal tube for the transmission of chloroform vapour from a Junker's inhaler is fixed to the prop, in the inner and back portion of which may be seen the orifice through which the chloroform vapour is pumped into the fauces. Two or three sizes of the chloroform-prop are needed. When in position it will be found that the lips remain flaccid although the teeth are separated. The little appliance is of great use in maintaining anæsthesia during throat and nose operations upon patients in the sitting posture. Provided that anæsthesia be induced by ether, that all respiratory embarrassment be avoided, and that too profound a narcosis be not maintained, chloroform may, I believe, be safely administered to patients thus placed.

CASES OF INJURY TO THE EPIPHYSEAL LINE.

BY RUPERT BUCKNALL, M.D., M.S. LOND., F.R.C.S ENG.

THE following cases of injury to the epiphyseal line have lately been seen at University College Hospital. The case operated upon was under the care of Mr. Horsley.

CASE 1. *Separation of the lower epiphysis of the humerus without displacement.*—A boy, aged three years, fell from a bed, injuring the left elbow. When seen several hours later the elbow was held flexed at a right angle and all attempts to move it caused pain. There was a considerable amount of puffy swelling about the lower end of the humerus and a slight groove could be made out above the capitellum posteriorly on careful examination of the bony surfaces. Measurement and comparison of the bony points with those about the opposite elbow showed no dissimilarity; but on attempting lateral movement of the forearm the lower extremity of the left humerus could be felt to "give" slightly on the shaft, and on internal movement the groove felt above the capitellum grew wider. A skiagram showed that there was no displacement of the epiphysis, and it could not be said that the epiphyseal line was broader than

normal. The limb was put up flexed on a moulded gutta-percha splint for three weeks, passive movement being begun on the tenth day and continued daily. At the end of a month no deformity could be detected and the movements were perfect.

CASE 2 *Separation of the epicondylo-capitellar epiphysis of the humerus.*—A boy, aged seven and a half years, fell from a tree on to the outstretched right hand six months before admission. The elbow was thought to be dislocated at the time and liniments were applied for some time, but the deformity persisted and limitation of movement increased. The arm was not "set" after the accident nor were splints applied. On admission the condition was as follows. The contour of the outer border of the arm was altered by a projection opposite the external condyle, as though the radius were dislocated outwards and upwards. The carrying angle was unaltered. The forearm could be flexed to an angle of 83 degrees with the humerus and extended through 50 degrees to an angle of 135 degrees. Pronation and supination were as extensive as similar movements of the sound arm. Attempts to flex or extend beyond the above limits caused pain. On examining the bones the inner portion of the humerus and the ulna were found to be normal and bearing their normal relations. The head of the radius rotated in the lesser sigmoid cavity freely and felt normal; above it articulated with an irregular mass of bone made up of the external condyle and capitellum with surrounding callus. The mass was displaced directly outwards, as is well shown in the skiagram (Fig. 1), not forwards or backwards. On running the finger down the external supra-condylar line the mass formed a distinct shelf projecting half an inch. The mass could not be moved on the humerus. Calipers showed the measurement from condyle to condyle on the right side to be 5·1 centimetres, as compared with 4·2 centimetres on the sound side. On exposing the mass through a curved incision it was found to be loose; it was therefore removed and the head of the radius being normal a groove was cut for it in the lower end of the humerus to allow of free movement. A splint was applied for two days, and the stitches being removed on the

FIG. 1.

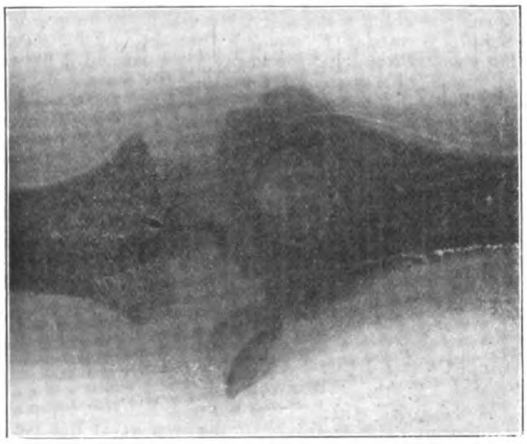


Illustration showing condylo-capitellar epiphysis in Case 2.

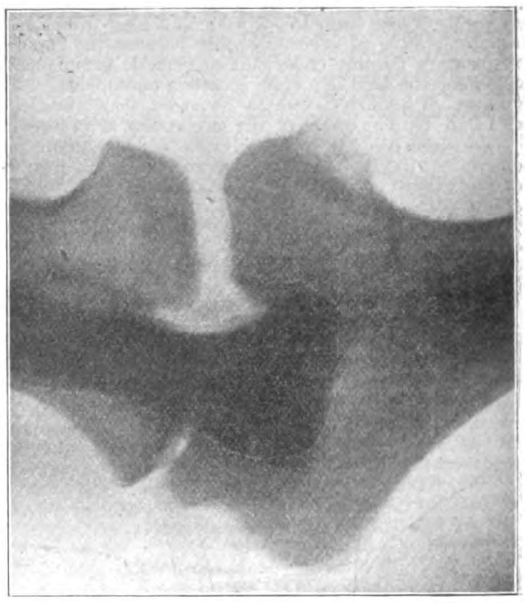
eighth day passive movements were begun and the patient was encouraged to move the arm. Three weeks later full flexion and extension were performed under gas, as there was limitation of these movements. Six weeks later the forearm could be extended to 160 degrees and flexed to an angle of 70 degrees with the humerus. Beyond this there was resistance but no longer pain. Pronation and supination were perfect and the carrying angle was slightly greater than normal. Three months after the operation the arm could be extended to 170 degrees and flexed to 70 degrees, all movements being freely performed and causing no pain. Pronation and supination were perfect and the patient used the arm in preference to the left one for all ordinary movements.

CASE 3. *Ununited separation of the epicondylo-capitellar epiphysis.*—A man, aged 56 years, gave the history that he fell on his left hand when 10 years old, injuring the elbow; this was "set" in splints, and it remained very stiff for some time afterwards. Both bones of the forearm were displaced a little outwards and the "carrying angle" was 20 degrees larger than normal, as measured in the opposite arm. The head of the radius could be easily felt, and above it, over the situation of the external condyle and capitellum, there was an irregular mass of bone which could be felt to move on full flexion or extension of the elbow. Both these movements were slightly restricted, but pronation and supination could be fully carried out. Behind the internal condyle there was a small mass of callus, fixed to the

FIG. 2.



Old epicondylo-capitellar separation (Case 3).

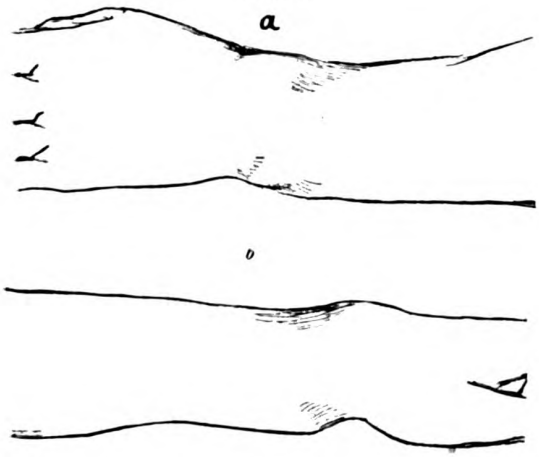
process, and evidently involving the ulnar nerve. The patient began to notice wasting of the hand and anæsthesia 20 years after the original injury, and now there was typical paralysis and wasting of the thenar and hypothenar muscles and the flexor and extensor carpi ulnaris, with anæsthesia in the area of distribution of the ulnar nerve in the fingers and hand as high up as the level of the pisiform bone. The nails of the fourth and fifth digits were longitudinally fluted. Operative treatment was refused, but the skiagram showed the relation of the bones and the position of the ununited fragment (Fig 2).

CASE 4. *Partial dislocation outwards of both forearm bones at the elbow; separation of the epiphysis of the internal condyle during reduction.*—A youth, aged 15 years, fell from a bicycle, striking the elbow against the kerbstone. When seen an hour later the elbow was swollen and flexed at an angle of 110 degrees, with the forearm pronated. The internal condyle was very prominent, and it was evident on inspection that the ulna was displaced outwards, but the dislocated radius gave rise to no marked deformity. The length of the line from the acromion to the olecranon was the same on either side. On examining the bones the deformity was at once evident, the sigmoid cavity of the ulna articulating with the capitellum, and the radius lying outside the external condyle, displaced also a great deal forwards. On the inner side the finger could easily explore all the trochlear surface of the humerus, and the trochlear notch could be readily defined. On the outer side the head of the radius lay to the anterior and outer side of the external condyle; it could be entirely explored and was felt to rotate on supinating the forearm. The elbow permitted of extension to 130 degrees and flexion to 100 degrees, and the forearm, which lay pronated, could be placed in the midway position between pronation and supination. Chloroform was given, and the dislocation was reduced easily by making extension

with leverage across the knee; but after the bones were replaced it was found that the epiphysis of the internal condyle of the humerus had been torn off. The separated fragment lay with its inner end or tip pointing downwards, just over the line of the joint, below and external to its normal position. On supination and extension it was drawn still further downwards and on pronation and flexion of the elbow, wrist, and fingers it could be replaced over its normal situation, but it always lay rotated with the tip pointing downwards. The whole limb was therefore put up on a splint in this flexed position and was kept at rest for ten days, at the end of which period the splint was removed and passive movement was begun and continued daily, the arm being kept in a sling for ten days more. There was a great deal of swelling and œdema, with blistering on the day after the accident. This slowly subsided and on the fourteenth day the elbow could be flexed to an angle of 70 degrees and extended to 170 degrees and pronation was perfect. Supination was slightly limited and the internal condylar epiphysis could not be distinctly made out owing to the callus forming round it. Two months later the movements of the elbow were quite perfect as to freedom and extent. The separated epicondyle could be felt as a mass firmly fixed to the humerus a quarter of an inch below its normal situation. The ulnar nerve was not tender and sensation in its area of distribution was normal.

CASE 5. *Separation of the lower epiphysis of the radius.*—A boy, aged 11 years, fell from a height of six feet on to his outstretched right hand, the thenar eminence striking on a step. There was obvious deformity at the wrist when seen two hours after the accident. The hand and the lower end of the radius were displaced backwards and outwards, forming a prominence on the dorsum of the wrist with a definite upper border to it extending across the posterior and outer surfaces of the forearm just above the wrist. The lower end of the upper fragment projected as a rather sharp ridge on the anterior surface, especially well felt about the position of the radial pulse, the artery arching over it (Fig. 3, *a* and *b*). There was no obvious rotation of the lower

FIG. 3.



Showing appearance of wrist in Case 5. *a*, From above. *b*, From outer side.

fragment either backwards or outwards. During reduction, which was easily accomplished, typical soft crepitus was felt. There was no tendency to re-displacement and a gutta-percha gauntlet was moulded on. Daily passive movement was begun at the end of the first week and kept up for 3½ weeks, at the end of which time the splint was discarded as the epiphysis had firmly united and the movements of the wrist and fingers were perfect. Two months after the accident no deformity could be made out beyond slight thickening about the epiphyseal line and the movements of the wrist were perfect. Fig. 4 shows the condition of the bones after reduction.

CASE 6. *Separation of epicondylo-capitellar portion of epiphysis of the humerus.*—A boy, aged six years, fell whilst spinning round at play and struck the left forearm and elbow against the pavement. When he was seen six hours later there was some swelling about the left elbow-joint which was carried at a right angle with the forearm semi-prone. On tracing down the external supracondylar line of the humerus an abrupt prominence could be felt about half an inch above the joint line and it was found that the external condyle and capitellum were displaced backwards and outwards about a quarter of an inch and also a little upwards; the fragment so separated had a sharp upper border posteriorly easily felt on running the finger down the smooth posterior surface of the humerus above the condyle. The measurement from the internal to the external condyle with calipers was nearly a quarter of an inch more on the affected side. The internal condyle and supracondylar line presented no deformity and the olecranon bore its normal relation to the condyle. The head of the radius could be easily felt lying below

FIG. 4.

Skiagram showing condition of bones after reduction in Case 5.

the displaced capitellum, the groove between them being broader than normal. Movements of the elbow caused pain, but under an anæsthetic they were free, though full flexion was limited before reduction. The fragment evidently consisted of the outer half of the lower end of the humerus, displaced backwards, outwards, and upwards. By direct pressure with the thumb it could be restored to its proper position, a soft "click" being felt during reduction. An attempt was made to put up the arm on a straight anterior splint in the extended position with a view to preserving the "carrying" angle at the elbow, but there was a tendency for the deformity to recur in this position. The elbow was therefore flexed as recommended by Hutchinson, and the fragment lay securely in an excellent position when the hand was placed over the opposite clavicle. Two strips of strapping were therefore applied exactly as in Sayer's method for treating fracture of the clavicle, a pad of wool being placed over the elbow beneath the strapping. The limb was found to be quite comfortable on the next day and needed no further attention till the tenth day, when the outer strip of strapping was removed and gentle passive movement of the elbow was practised in all directions. This was repeated daily for 12 days, the fragment being held in place by the fingers during manipulation and the strapping being reapplied. Full range of movement was soon reached without causing pain and after the first day the patient did not cry. At the end of three weeks from the date of injury the arm was placed in a sling and the mother of the boy was enjoined to move it twice daily to the full. Union appeared to be quite firm in three weeks from the date of injury and first treatment. Eight months later the limb was examined. There was full and free range of movement in every direction. There was some prominence about the line of fracture due to callus, but no gross deformity. The groove between the upper end of the radius and capitellum was broader than normal, as though there were some want of growth of the outer half of the lower end of the humerus, but the "carrying" angle of the elbow was exactly similar to that on the opposite side.

The first case described, in which there was no displacement of the epiphysis, is a good example of the rather equivocal signs which separation of an epiphysis may present. It is important, however, to recognise the

condition and to fix the fragments for a time, as otherwise undue mobility may lead to permanent want of union. Such a result is very rare without displacement, and a more common sequel is the formation of an excessive amount of callus from the same cause, leading either to destruction of the epiphyseal line or to interference with its blood-supply. Both these pathological processes may lead to a want of growth on the part of the bone affected, and if such want of growth occurs in one of two parallel bones, or in one half of a broad epiphysis, angular distorsion of the joint may result, as is shown in Case 3.

The difficulty in recognising the exact form of injury present in epiphyseal separations depends on the small size of the parts in children and the way in which the bony processes are obscured by the subcutaneous fat. In order to come to a correct conclusion and to effect efficient reduction of any deformity present an anæsthetic is always necessary and careful measurement must be made of the bony points, comparing them with those on the sound side. It is often difficult to fix accurately the fragments after reduction for the same reasons, and moulded splints of poroplastic or gutta-percha will be found far more serviceable than those of wood or metal and very easy to apply.

The proximity of the injury to a joint always leads to a rapid effusion into the synovial cavity, often consisting of blood. An important point in treatment, therefore is the early passive movement, which should be carried out in order to prevent the formation of adhesions with permanent limitation of movement in consequence. This must be begun before the fracture is sufficiently firmly united for splints to be discarded, and about the seventh or tenth day the limb should be taken down off the splint, and the fractured region being kept fixed by grasping the fragments with the hands an assistant should proceed to move the joint. Very slight range of movement is all that is necessary at first, but all the normal movements of the joint must be commenced; thus at the elbow or wrist pronation and supination must be practised as well as flexion and extension. A similar passive movement must be carried out each day, and each day the range of movement may be increased, and even at the end of three weeks or a month, when the splint is discarded, it is as well to continue such treatment for another period of three weeks, especially if any pain or stiffness persist.

Case 2 shows deformity and pain resulting from improper treatment of a fairly common injury about the elbow in children. One of two lines of treatment may be adopted in such a condition. If seen sufficiently early the separated fragment may be wired or pegged in its proper position, a proceeding which may lead, not only to union, but to restoration of growth about the epiphyseal line; but if seen late, as here recorded, no such new growth could be expected and the obstruction to movement and the pain caused by the callus are best overcome by removal of the fragment. The portion of bone removed in this case was much distorted by the addition of callus, and no trace of the epiphyseal line remained, so that no new growth could have subsequently taken place

The fourth case is an example of a fairly common complex injury, though the epiphysis of the internal condyle is more often torn off at the time of dislocation than, as here reported, during reduction. This injury has on several occasions been overlooked, and failure to recognise it has led to ulnar paralysis from want of immobilisation and excessive formation of callus, the latter pressing on the nerve. Treatment by immediate wiring or fixation of the fragment in position by strapping has been recommended. The latter was impossible in the present case, as no hold could be gained on the fragment, nor would the subsequent swelling that ensued lead to an unqualified recommendation of this method.

Immediate wiring is certainly the ideal treatment if asepsis can be assured, but infection, however slight the risk may be, leads to such serious results in these cases that any line of treatment evading the possibility of such an accident is certainly worthy of consideration.

Case 5 shows a simple separation with displacement of the lower epiphysis of the radius and the usual accompanying deformity which differs slightly from that seen in Colles's fracture. Considerable force is as a rule needed to tear off this epiphysis, and in consequence many of the cases recorded have been compound separations, the lower end of the diaphysis tearing through the skin and often injuring the radial artery.

University College Hospital, W.C.

NOTE ON THE TREATMENT OF COLLAPSE OF THE ALA NASI.

BY W. J. WALSHAM, F.R.C.S. ENG.,
SURGEON AND LECTURER ON SURGERY TO ST. BARTHOLOMEW'S HOSPITAL.

COLLAPSE of the ala nasi is a condition well known to those interested in nasal surgery. It consists in the falling of the external part of the lower lateral cartilage inwards during inspiration, so that it comes in contact with the septum and prevents the patient from drawing air through the nasal chambers on the affected side. Normally the lower lateral cartilage is doubled on itself, U-like, the inner part being in contact with the lower end of the septum, whilst the external forms a part of the outer wall of the vestibule. There is an amount of stiffness in the cartilage which keeps the anterior nares patent and the resiliency of the cartilage where the bend occurs is sufficient, after the two portions of the cartilage have been pressed together, to restore the patency of the anterior nares. In not a few individuals this resiliency is lost, and during inspiration the outer wall of the vestibule comes into contact with the septum. In some of these cases there co-exists a dislocation of the anterior end of the septum from the columella, and this, when present, increases the obstruction to free inspiration.

Although this collapse of the ala may be called a trifling affection it is astonishing how much annoyance it gives to the subject of it. It may easily be overlooked by the surgeon unless he is cognisant that such a condition may occur. For when the speculum is introduced and the blades are separated the collapsed ala at the same time is of course carried away from the septum by the external blade of the speculum and nothing whatever may be discovered on looking into the nasal cavities to account for the patient's trouble. The surgeon should suspect this condition, however, if when nothing abnormal is seen in the nasal chambers the patient remarks that he breathes quite comfortably with the speculum *in situ*. If now the speculum is removed and the vestibule is examined by tilting up the tip of the nose with the finger it will be seen that the outer wall comes in contact with the inner when the patient inspires.

The condition is an exceedingly troublesome one to treat. I think I have seen some good done by face massage—that is, massage of the dilator muscles of the ala—but not much. When there is dislocation of the anterior end of the septum shaving off the projecting portion will also help matters, though it will not completely rid the patient of his trouble. I have used the various rings, semi-circles, celluloid expanders, short pieces of drainage-tube, &c., that have been from time to time recommended for the condition, and although they may keep the passage expanded whilst *in situ* and for the time give relief they soon become irksome and irritable and are abandoned. In one case under my care I had made a number of similar contrivances of various material carefully moulded and shaped to fit the part accurately. But this patient, like the rest, finally threw them aside and resorted again to his own plan of obtaining relief—namely, rolling up a piece of moist cotton-wool into a ball of the size of a small pea which he poked up the vestibule into the little pit just within the limen at the angle of bending of the lower lateral cartilage. This tiny ball of cotton-wool was just sufficient to prevent the ala from collapsing and it gave me the clue to the method of curing the condition. It struck me that if in place of the cotton-wool ball I could transplant there a ball of the patient's own tissue I should obtain the same end, and this I succeeded in doing in the following way. A strip of mucous membrane as thick as possible and about three-sixteenths of an inch in width was dissected up from the inner wall of the vestibule, leaving the base attached above. The surface of the little pit at the angle of bending of the lower lateral cartilage was next made raw by removing the epithelial layer. The epithelial lining was also removed from the little strip of tissue; the tissue itself was rolled up bandage-wise and then secured to the rawed surface of the pit by a stitch of the finest fishing-gut passed by a needle through the septum into the opposite nostril and back again. When thus fixed the little roll of tissue pressed out the external portion of the lateral cartilage just enough to prevent the ala during inspiration from falling into contact with the septum. It cannot be seen and produces no

deformity, and so far as my experience has gone it is a permanent cure for this troublesome condition. The surface left by rolling up the strip of mucous membrane readily granulates over and causes no inconvenience. Tension in the strip of tissue must of course be avoided and care must be taken that the surfaces of the roll are properly and completely bared and their vascular supply not interfered with by drawing the stitch too tight. The operation is best done under general anæsthesia, as unless the tissues are manipulated delicately the blood-supply of the little strip will be injured and necrosis will take place.

Harley-street, W.

THE TREATMENT OF SCIATICA, ARTHRITIS DEFORMANS, AND SCLERODERMA BY SUPERHEATED DRY AIR (THE TALLERMAN SYSTEM).

A REPORT FROM THE LANDESBAD AT BADEN-BADEN.

BY DR. FR. NEUMANN.

IT is seldom that a specific method of treatment withstands the test of years and continues to fulfil its original promise so well as the Tallerman system for the application of superheated dry air. The apparatus itself has been so frequently described that I may confine myself to a brief indication of its essential features, though there are, on the other hand, thousands of physicians who have not yet seen it. Two different forms are used: (1) for the pelvis; and (2) for the extremities. The apparatus can be heated by electricity or by gas or even by oil, and the temperature in the interior is brought up to 300° F. That such temperatures are actually reached in the upper part of the cylinder is proved by the reading of the thermometer affixed to the top; but whether temperatures so high as the thermometer indicates are maintained inside in an equal degree—whether a limb lying in the apparatus is surrounded by a uniformly heated atmosphere so that we can speak of the *continuous* action of superheated air when once the maximum is reached—that question has hitherto been a matter of assumption. I have endeavoured to solve it in a simple manner. When any portion of the body is inserted in the cylinder the floor on which it rests is protected by a cushion of asbestos resembling a thick layer of felt. Above this and around the limb a covering of woven asbestos, which is like lint in appearance, is disposed. The patient must be completely undressed and comfortably wrapped up in loose cotton wraps and blankets on account of the profuse perspiration which usually occurs during and after the sitting and also to ease the respiration and the action of the heart. Obviously the limb is not exposed to the direct action of the hot air, and for this reason—that if it were left uncovered the *radiant* heat from the metal falling on to the skin must have either a scorching or at least a very irritating and painful effect. The loosely clothed portion of the body inside the apparatus experiences in general no disagreeable sensations from the heat. Where the covering comes into direct contact with the skin the feeling is only one of moderate warmth, but where between the folds hot air has free access to the cuticular nerves one has the sensation of a very intense but comforting heat. The dry air enveloping the limb must obviously draw from it a large amount of moisture through the difference of temperature and saturation; and it follows from elementary physical laws that as large quantities of moisture are withdrawn more and more blood is forced to flow from the deep-seated tissues, where it is cooler, to the heated surface and into the dilated vessels of the skin. For a closer examination of these processes, however, further investigation is needed.

It is a fact that the coverings in which a limb rests when under treatment become moist and that occasionally in a fold of asbestos shut off from evaporation a small quantity of water—unquestionably the product of condensation—may collect; and yet such moisture never becomes superheated, for otherwise scalding would occur, and this we have never observed at the Landesbad in upwards of 2000 applications. Nor is a single case of scalding noted in the whole of the English literature which I have perused. It is a matter for regret that in dealing with such an exceedingly beneficent method of treatment as this all the internal processes should not yet be fully known. Certain it is, however, that the withdrawal of moisture from the limbs must be accompanied by considerable changes in temperature, and further that it is impossible to speak of a constant dry heat in view of the fluctuations in temperature and moisture. In order to obtain at least some authoritative data for commencing the investigation of these points I had a maximum thermometer constructed which can be placed between the asbestos coverings during the sitting and read afterwards. The following table gives the temperatures noted:—

In the apparatus. Degrees Fahrenheit.	Maximum thermometer. Degrees Fahrenheit.	Difference. Degrees Celsius.
225	179·6	25·0
230	195·8	19·0
220	194·0	10·5
260	230·0	10·8
238	212·0	14·0
220	190·0	16·0
250	230·0	11·2

This table shows that inside the cylinder in the course of an hour's use considerable variations in temperature occur, which certainly cannot be without influence on the contents of the superficial blood-vessels and on the amount of evaporation. Immediately after leaving the apparatus the limb is injected and of a uniform red, but has not the slightest appearance of cyanosis or stasis. During treatment the whole body falls into a pleasant perspiration; the pulse is accelerated by some 10 to 20 beats in the minute, but is not noticeably full or dicrotic, still less small and irregular. Cardiac or cerebral sensations of a disagreeable character only occur in highly nervous patients, in whom the mere apparatus—or the "oven" as people often call it—of itself excites alarm. With increasing experience and observation I have been able, as others have done, to apply the treatment without anxiety to patients suffering from arterio-sclerosis, myocarditis, and moderate valvular disease.

Here, as elsewhere, observations of the temperature taken in the mouth or axilla have shown that there is never an important increase in the body-heat, the rise scarcely reaching ½° Celsius as a rule. This conclusion is confirmed by the fact that treatment never induces albuminuria, but rather that it diminishes existing albuminuria from organic kidney disease.

English writers represent the curative action of the treatment in a light which we cannot altogether endorse. My own belief is that super-heated dry air will come much more into general use as a therapeutic agent and will obtain permanent recognition if attention is directed strictly to the results derived from a wide field of observation. Among the English contributions to the subject we find the statement repeatedly made that the local action in a limb or joint on one side of the body benefits the corresponding part on the other side in a striking manner. I willingly admit that the general stimulation of the circulation and of perspiratory excretion may produce general relaxation of the tissues and relief from pain, but our observations afford no evidence that a curative effect is actually transferred from one side to the other by a sort of sympathetic action—whatever that may mean. Equally doubtful, in my opinion, is the assertion that in arthritis deformans, for instance, or in neuralgia such as sciatica, a striking and immediate remission of pain sets in. Nor is the reduction of swollen joints effected so rapidly as is stated in many reports. On the other hand, it is unquestionable that in many cases the curative action continues after treatment. The improved circulation and marked stimulation of the lymphatic system lead in many cases to vigorous nutrition of the parts affected; and so it happens that patients are discharged, going somewhat dejectedly away on crutches and sticks apparently unimproved and uncured, of whom we subsequently hear that improvement, cure, and ability to return to work have been gradually established. It is also much truer to nature that the healing process should follow this course than that of suggestive and miraculous change. Further, the gradual improvement in the condition of atrophied muscular tissues, the increase

in power and bulk of wasted limbs, can only proceed by degrees and by means of improved nutrition. We notice this strengthening of the muscular system after the application of the Tallerman treatment even in cases in which, for the sake of experiment and observation, we have given up the simultaneous use of the Zander exercises. Whether we shall succeed, as some enthusiasts believe, in completely suppressing arthritis deformans, for instance, or in abolishing it altogether out of existence will appear highly doubtful and unlikely to every physician familiar with this terrible disease.

Observation has shown that this treatment, energetic as it seems to be, produces no ill effects either on the local seat of mischief or on the whole system. In particular we have never been able to discover that it causes any wasting or has a lowering effect on the general strength, although it is so powerful and compressed into so short a space of time. On the contrary, in precisely the most successful and at the same time the severest cases the general health and appearance have notably improved, through the relief from pain, as we must suppose, and the powerful stimulation of the circulation.

In this general survey my object has been to show how the hot air acts, and I believe that I have correctly defined the scope of its action. Just because the Tallerman treatment is a blessing to so many invalids I have impartially depicted light and shade to the best of my knowledge. With regard to the application of the treatment to the cure of particular classes of disease much has been written already in England, America, France, and Germany. In Germany the Baden Government, at the instance of the Minister of Medicine, arranged with Mr. Tallerman in the year 1898 for the installation of his apparatus for the public use at the Landesbad, the great State institution for gout, rheumatism, neuritis, and heart disease, and also at the Friederichsbad, the well-known thermo-hydropathic establishment for private patients. As senior physician to the Landesbad I have myself had abundant opportunities of employing the treatment. In order to appreciate the results properly it should be noted that the majority of the patients at the Landesbad are recruited from the necessitous classes—that is to say, we have agricultural labourers, factory work-people, public servants much exposed to the weather and to great physical exertion, such as railway and custom-house employés, together with the women belonging to the same class of life. It is no wonder, therefore, that abundant material for the hot-air treatment should be forthcoming. We have a large number of the severest cases of so-called sciatica (190 cases in 1900), in which the form of illness and its incapacitating effects vary according to the seat of the disease and the acuteness of the attack. True gout is comparatively rare among our patients. On the other hand, affections resulting from acute arthritic rheumatism and—whether allied to them or independent—the various forms of chronic articular rheumatism and the so-called arthritis deformans, into the pathology of which I will not enter here, are all very common (about 300 cases).

It is precisely in dealing with the foregoing maladies that the hot-air treatment is most valuable. The position of physician to an establishment like the Landesbad no doubt gives one the opportunity of gaining vast experience in a particular direction; but, on the other hand, it is one's duty to keep testing again and again the value of the old-established means—hot springs, hot air, and vapour baths—and to apply the combination of these with fango and exercise on parallel lines to the same morbid conditions. To enter fully into the details of this procedure would carry me too far afield, but this much I can say—that both at the Landesbad and in private practice the patients submitted to the Tallerman treatment have been the bad and very bad cases only.

Speaking generally, my indications for the treatment correspond with those set forth more particularly in the English literature. There the morbid conditions dealt with are chiefly rheumatic neuritis, chorea, gout, chronic rheumatism, rheumatic arthritis, stiff and swollen joints, sprains and ruptures of joints, fractures, inflamed flat-foot, &c. In England, on the other hand, they have also treated eczema, of which I have had no experience, whilst for my part I have had the opportunity of treating subacute nephritis, three cases of scleroderma, and one of myxœdema. In the course of the year we have applied the treatment to cases of sciatica and lumbago (70 cases), arthritis deformans (35 cases), chronic arthritic rheumatism, badly-mended fractures with interruption of the circulation, severe sprains of the pelvis and spine, painful cicatrices and contractions after gunshot wounds, three cases of scleroderma, one of myxœdema, and also cases of inflamed flat-foot. No result whatever was obtained in three cases of sciatica, in one of sciatica and lumbago with special involvement of the ileo-inguinal nerve, and in one of ankylosis of the knee-joint following operative removal of rice-seed bodies. Unequal results were obtained in two cases of arthritis deformans, the hands being improved as regards swelling and mobility while the knees remained unaffected and very painful. Unimproved also were two cases of apparently old fracture of the neck of the femur with severe concussion of the pelvis, and hardly any success was obtained in one case of inflamed flat-foot and one of scleroderma, in which only the hands were relieved. All the remaining cases were either substantially improved or completely cured. In many cases the improvement is of such a character as to make a truly wonderful impression upon the patients and their friends, and it may be said of them that they would otherwise remain absolutely incurable. I append a few such cases.[1]

SCIATICA.

CASE 5.—The patient was a man who had to travel a great deal. The cause of his illness was repeated chills; otherwise he was quite healthy. There were bilateral sciatica, extreme pain, and insomnia; the slightest movement—walking, sitting, or standing—was impossible; the gluteal nerves were particularly affected. He was unable to leave his bed for five months. All previous treatment was useless. Pelvic Tallerman treatment, alternating with natural baths, were given. Complete cure resulted in two months. The patient, who would otherwise have had to give up his livelihood, now carries on the whole of his exacting business as before. The cure is now of seven months' standing.

CASE 222.—The patient was a woman who had overstrained herself while sick-nursing and was supposed to be suffering from inflammation of the right hip. She had been under treatment in the hospital for three months without any improvement worth mentioning. On examination she was found to have gluteal sciatica. The hip was freely moveable; there was total inability to walk. She had great pain even in bed. Pelvic Tallerman treatment was given; there was complete cure in four weeks. There has been no return.

CASE 92.—The patient was a man who had severe sciatica following fracture of the neck of the femur. He had violent pain, atrophy of the muscles of the thigh, and was unable to walk for months. Pelvic Tallerman baths were given; he walks freely and without pain.

CASE 107.—The patient was a woman suffering from bilateral sciatica; she was sent to me after being bedridden for six months for osteo-malacia. She was deprived of almost all power of movement in the pelvis and legs; she tried to walk with a supporting frame, such as little children use. Double sciatica was diagnosed. Pelvic Tallerman treatment was given; in six weeks the patient left the institution walking easily with a stick, but had a return after getting a chill in the kitchen.

CASE 116.—This patient had a stiff knee; the thigh was flexed, there was pain in the left sacro-iliac joint and wasting of the left thigh; the patient had to be carried and could only walk with a stick by the greatest effort. Complete cure resulted and she now walks easily.

CASE 129.—The patient had bilateral sciatica; there were pain in the sacrum and sacro-iliac joint and shooting pains in the ileo-inguinal regions; the patient walked bent double and there was wasting of the left thigh. Result: the patient is completely free from pain and walks upright.

CASE 292.—The patient had ankylosis of the spine, lumbago, and sciatica, under the guise of coxitis; there was inflammation of the shoulder-joint and the arm could scarcely be raised to the horizontal position. Result: there is free movement of the hips, the spine can be flexed and turned, the arms can be raised high without pain, and the patient walks well.

CASE 474.—The patient had left sciatica; there were wasting of the gluteal muscles and pain in the gluteal nerves; the sacrum and sacro-iliac joint were painful; the right shoulder moved with difficulty. Complete cure resulted.

[1] Some case-notes from private practice are included; the rest are from the Landesbad.

CASE 643.—The patient had inflammation of the left hip-joint. On examination a diagnosis was made of gluteal sciatica only; the patient had been treated with weight and pulley for six months and was sent to us by an eminent surgeon as probably suffering from sciatica; a few steps only could be taken on two crutches and with great pain. Pelvic Tallerman treatment was given and the patient walks easily with one or two sticks.

CASE 710.—This patient arrived quite bent double and was scarcely able to walk. There was left sciatica, the gluteal nerves were particularly affected, and there was atrophy of the left gluteal muscles. The disease was of six years' standing. Pelvic Tallerman baths were given; great improvement resulted, and the patient can go to work and bends and turns the lumbar spine without pain.

ARTHRITIS DEFORMANS.

CASE 3 and 720.—This patient since 1899 had suffered from gradually increasing stiffness of both shoulders and could not raise the arms; the left wrist was stiff, the knees and the ankles were swollen and painful, and the fingers were stiff. The patient had to be carried into the Landesbad. Walking or writing could not be done and the patient was perfectly helpless. After a course in the spring and again in the autumn the patient got completely well, is free from pains, and walks, writes, and raises the arms above the head.

CASE 253.—The patient had arthritis deformans of the hands and all the finger joints; it had been gradually coming on for four years. The patient was unable to work. After treatment the right wrist was somewhat stiff, but the fingers were no longer swollen or painful and were freely moveable. The fingers can now be flexed, writing and knitting can be done, and the patient is fit for work again.

CASE 375.—The patient had arthritis deformans following influenza of two years' standing; the ankles and knees were attacked and the hands were severely affected. The patient could not work. After treatment walking was easy and the hands were free from swelling and pain. The patient can now return to work.

CASE 43.—The patient had typical arthritis deformans in both knees and in 1899 could not walk, had to be carried, and left the institute walking with sticks. In 1900 there were further improvement and perfectly free movement. The patient is completely cured.

CASE 44.—The patient had arthritis deformans of both knees, which were stiff and fixed at an angle. After treatment the swelling disappeared, there was free painless movement, and the patient walked upright.

CASE 78 and 870.—The patient had arthritis deformans of both knees and ankles. There were atrophy of both thighs and calves and pain in the sacrum. On arrival in the spring the patient could not walk, had to be carried, and could not rise from the sitting posture without help. The right shoulder was stiff. Result: swelling of the knees has subsided, walks easily, and the right shoulder is better. The patient can return to work.

CASE 90.—The patient had severe arthritis deformans of both hands. She could not close the hands and could not follow her calling as teacher. After treatment the hands were still somewhat swollen but were freely moveable. There was progressive improvement after discharge, so that the patient is now completely free from disease and fit for work.

CASE 135.—The patient had rheumatic ankylosis of the lumbar and middle vertebræ; the spine was slightly scoliotic but absolutely immoveable, like a fixed splint; bending and turning were impossible; the knees were swollen and painful. After treatment the spine could bend and turn, though movement was limited, the knees were free, and the patient is fit for work within limits.

CASE 654.—The patient came in 1899 with arthritis deformans in the knees and ankles and flexure of the hip. He had to be always carried and he left apparently without any improvement. Some months later the swelling of the affected joints subsided. The patient was free from pain and walked well, but as the same trouble still remained in the right ankle he underwent another course in 1900, and left the hospital a capital walker and a thoroughly healthy man.

I add here some other diseases which have undergone the Tallerman treatment. Highly interesting, and the first successful one of its kind, is a case of scleroderma, which I shall describe somewhat more in detail, as this disease has not previously been treated by the Tallerman method.

SCLERODERMA.

CASE 236.—The patient was a woman, 46 years of age, in whom the disease had begun six years before. The cause was unknown. The skin was affected on the abdomen and chest, almost the whole of the back, the feet, and the lower part of the legs, knees, fore-arms, and hands. As for the last, the disease was so far advanced, particularly in all the fingers, the left wrist, and the back of both hands, that the skin could not be moved in the slightest degree. With fingers crooked like talons and standing out from each other, the hands presented a rigid whole as if chiselled out of stone, and the illusion was such that in examining them one was almost afraid of snapping a finger right off. The woman could scarcely walk, as the legs and feet were similarly affected, and, moreover, the sclerosed skin at every attempt to move and even spontaneously, particularly at night, caused her maddening pain. The sensibility of the skin was preserved, but, on the other hand, not the slightest sign of perspiration could ever be produced even when the affected parts were exposed to the hottest sun. The mail-like skin on the back and chest prevented proper respiration. The heart, urine, and lungs were free from abnormal signs. The patient presented an appearance of frightful misery and wretchedness. Her features were also distorted by pain, for the disease had begun to attack the face. In the year 1879 I published a case of scleroderma in Virchow's *Archiv* in which I had attempted to ascertain the condition of the sweat glands by pilocarpine injection, but without any success in inducing perspiration. I had also removed a piece of diseased skin and made some microscopical sections. Of the sweat glands some thin threads could still be distinguished embedded in dense fibrous tissue. With this experience in my mind I had recourse in the present case to the Tallerman treatment with very faint hopes. After a few sittings, however, perspiration was induced not only in the unaffected parts, but also in the hands and feet under treatment in the apparatus. The pains subsided, the skin began to be moveable again, the fingers lost their claw-like appearance and could be brought closer together. The patient began to walk better. After a stay of four weeks she left the institution. On Oct. 11th she returned and informed us that the improvement had steadily progressed. Her appearance was materially better; her previously depressed frame of mind had given place to a lively expectation of becoming once more able to work. She walked with ease, and could sit down and get up without any of the difficulty and pain she had previously felt, and the skin was looser. Even in the hands, which were still in need of further improvement, though the fingers could almost be closed, she had the feeling that they "were alive again." At the beginning of 1901 she could write, knit, walk, was free from pain, and much stronger.

MYXŒDEMA.

CASE 652.—The patient was an unmarried woman, 34 years of age, previously healthy. In 1898, after being severely poisoned by gas, she began to suffer from myxœdema, which chiefly attacked the lower part of the back, the buttocks, and the thighs. She was for some time in the hospital for nervous diseases at Strasburg, and was sent to me from there. She was very anæmic and very depressed; she wept readily and was somewhat weak mentally. She could scarcely walk and had to be half carried into the Bad. The skin was greatly thickened, pale, doughy, infiltrated, and scarcely moveable on the underlying tissues. She was first treated with inhalations of oxygen and hip baths. As soon as she became somewhat more composed the Tallerman treatment was applied. The skin became distinctly thinner and more moveable; she improved greatly in appearance and strength, and eventually could walk by herself not only into the town but to the old castle, a distance of three miles with a rise of 600 feet.

The improvement in this case cannot, of course, be attributed to the hot-air treatment alone, but it had, at any rate, a favourable effect on the condition of the skin. In sciatica and chronic articular rheumatism I have seen good results obtained in a great many cases by combining other methods of treatment—for instance, by alternating ordinary warm baths with hot air or hot air with fango, and that in very severe and old cases. But in the end one picks out the most hopeless and intractable cases for the Tallerman

treatment, and I am bound to say that there has hitherto been no method of treatment so capable as this of improving arthritis deformans as to effect the abolition of pain, the restoration to work, and a new lease of life. Such cases could only be compared in their hopelessness with far advanced pulmonary tuberculosis. All that we could previously give these unfortunates was pity and some mitigation of suffering. The Tallerman treatment has accomplished a most gratifying revolution in this field of medicine and is worth more than all previous remedies put together. The improvement obtained in ankylosis of the spine, which is closely connected with arthritis deformans, justifies us in entertaining hopes for many departments of orthopædic surgery, and the success in scleroderma described above places this disease, which has hitherto been regarded as incurable in its severer forms, in a more favourable light from the therapeutic point of view.

NOTES ON A CASE OF TEMPORO-SPHENOIDAL ABSCESS FOLLOWING MIDDLE-EAR SUPPURATION; OPERATION; RECOVERY.

BY PERCY JAKINS, M.D. DURH.,
SURGEON TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL.

A MAN, aged 24 years, was admitted into the Central London Throat and Ear Hospital on August 21st, 1899, complaining of great nausea and giddiness and an excruciating headache over the frontal and occipital regions and on the right side of the vertex. There was a clear history of phthisis, four of his relatives having died from this disease. The patient had had whooping-cough at the age of four years, and measles when he was a year older; when he was 10 years old he had scarlet fever, and three years previous to the time of his admission to hospital he suffered from influenza; the ears had not been affected in any of his illnesses. For two years he had had a discharge from the right ear, the cause of which was unknown. Five months before admission he attended a special hospital for this discharge; a polypus was removed, and he was told to syringe his ear with a lotion and to have a white powder blown into it, but neither the removal of the polypus nor the treatment prescribed caused any diminution of the discharge which became offensive. 17 days before admission (August 4th) the patient was said to have complained for the first time of pain about the right ear (especially over the mastoid) which extended to the head and was accompanied by vomiting on that day. The pain increased in severity during the next seven days and Dr. John Cross of Gloucester-road, N.W., who was called in, found the patient suffering great agony; the patient's sufferings were somewhat relieved by the free use of sedatives. On August 14th he appeared so much better that he went out for a walk for a couple of hours, and on the evening of the same day was able to play the piano; next day, however, he relapsed into his former state and became worse, and a second attack of vomiting occurred. The patient's appetite appears to have kept very good, but his relatives had noticed that for some four months before this attack he constantly complained of being cold, and was accustomed to crouch beside the fire, although it was warm weather; there was no history of a distinct rigor. The temperature was noted from the 16th until the date of his admission; the highest recorded was 101·4° F. on the evening of the 20th; the lowest was 98·4° on the morning of the 19th. The bowels had been very constipated, necessitating the free use of aperients.

On admission the temperature was 99·4° and the pulse was 64. The patient had severe pain all over the right side of the head, the right mastoid was very tender on pressure, and there were marked giddiness and nausea; the complexion was very pale, there were sordes on the lips and tongue, and the breath was decidedly offensive. The patient was heavy and drowsy, his speech was slow, and his body was much wasted. On examination the meatal canal was found to be full of offensive pus, and when this had been removed there was seen to be a distinct bulging of the superior and posterior meatal wall. On the following day (August 22nd) the patient, whose temperature was 98·4° at 10 A.M., was placed under chloroform, the part having been previously shaved and rendered aseptic, and a semilunar incision was made over the right mastoid from the lower border of the temporal muscle to the apex of the mastoid, the periosteum was reflected, and the cartilaginous part of the meatus was separated from the osseous. The ear having been drawn forward the antrum was explored and was found to contain granulation tissue and cholesteatoma; this was curetted. The attic was found to be in a similar condition and was treated in the same way, and a communication was found leading to the middle fossa, the dura mater being exposed. The skin incision was carried upwards, the temporal muscle was divided, the periosteum was reflected, and a piece of bone was removed by the trephine. As the dura mater looked healthy and there was no bulging I decided not to explore the cerebrum, feeling sure that if an abscess was there it would make its way towards the point of least resistance. The wound was packed with iodoform gauze and the patient was put back to bed. On the next day the patient felt decidedly better, the headache was less, and he had slept fairly well; the highest temperature for the day was 99·4°. On the following day he expressed himself as feeling quite well; the highest temperature for the day was 99°. On the 25th the patient suddenly became exceedingly restless and complained about noon of severe headache, especially over the occipital region. He soon became drowsy and then comatose, and the nurse noticed that he did not move his left arm or left leg. I was sent for, and I found that the patient had complete left hemiplegia. Chloroform having been given, on removal of the packing the dura mater was seen to be bulging through the trephine opening. The dura mater was incised, a medium-sized trocar and cannula was then driven into the brain-substance for a distance of one and a half inches, and on withdrawing the trocar a very offensive pus escaped. A Horsley's pus seeker was next used and the abscess cavity was emptied of its contents, about two ounces. A large drainage-tube having been passed into the cavity the wound was packed with gauze. The temperature was 97·4° at 6 A.M. The evening temperature (taken at 5 30) was 103·0°. The patient was very restless, continually moving his right leg; in a short time he began to move his left leg. Next day (August 26th) he was better and could move his left arm and leg; the highest temperature for the day was 102·8° at 2 P.M. On the 27th the highest temperature for the day was 101·2°. On the 28th, as the patient was very restless and almost maniacal, shouting and trying to get out of bed, the night nurse was obliged to send for my colleague, Dr. Peter H. Abercrombie, who prescribed 40 grains of bromide of potassium, followed in half an hour by a subcutaneous injection of one-third of a grain of morphia; after this the patient slept well. The highest temperature for the day was 101° at 10 A.M. On the next day the drainage-tube was removed, cleaned and shortened, and re-inserted; the highest temperature for the day was 100·4 at 2 A.M., and it was thenceforth normal. The patient made an uninterrupted recovery. The tube was removed on Sept. 20th and he left the hospital two days afterwards, having been resident for 33 days. I examined him on Dec 9th and found him quite convalescent. To use his own words, "he felt better than he ever did," and he had gained weight and strength.

This case, I think, bears out the opinion which I hold that the presence of a polypus or granulation tissue in the external meatus indicates trouble in the antrum or attic or both, and that simple removal of the growth through the external meatus in no way touches the disease which is causing the trouble. It also illustrates another point—namely, that in cases of suppuration from the middle ear which do not yield rapidly to treatment the advisability of the radical operation should be seriously considered, not only with the view of arresting the discharge from which the patient suffers but to prevent deeper mischief, such as cerebral abscess. Within the last two years I have operated upon four cases of cerebral abscess caused by extension of mischief from the middle ear.

For the full notes of the foregoing interesting case and for the necessary after-attention upon the patient I am indebted to my colleague, Dr. Abercrombie.

Harley-street, W.

"SELENIUM COMPOUNDS AS FACTORS IN THE RECENT BEER-POISONING EPIDEMIC."

BY F. W. TUNNICLIFFE, M.D., M.R.C.P. LOND.,
AND
OTTO ROSENHEIM, PH. D., F.C.S.

WE have quite recently [1] drawn attention under the above title to the fact that selenium was present in a sulphuric acid obtained from the maker implicated in the recent epidemic and in two samples of beer obtained from a Salford brewery. Since then we have also found it in an invert sugar obtained from Bostocks.[2] Our quantitative estimations of selenium in beer and brewing sugar have confirmed our original conclusion "that selenium compounds have played a definite rôle in the recent beer-poisoning epidemic, their part being, however, subsidiary to that of arsenic." Although we intend to publish later our results and methods in detail, together with further observations, it is important so far as concerns the subject matter of this note to state that in the samples of beer examined by us selenium dioxide was present in quantities amounting to from one-fourth to one-third of the arsenic.

In an interesting paper by Dr. W. H. Willcox in THE LANCET of March 16th, p. 778, attention is drawn to the influence of selenium upon the formation of the arsenical mirrors obtained by Marsh's test. These observations, however, refer to the presence of selenium in large excess (from double to 20 times the amount of arsenic). Dr. Willcox is evidently unaware of the work of L. Dawydow.[3] This observer drew attention to the retarding and even completely inhibitory influence of relatively large quantities of selenium upon the formation of arsenical mirrors, and gave methods for its elimination. We were some time ago able to convince ourselves of the correctness of Dawydow's observations. At the same time we obtained conclusive proof that when the selenium present amounts to from one-fourth to one-third of the arsenic it practically does not interfere with the formation of the arsenical mirror, this latter not being distinguishable from a pure arsenical one. With regard to Dr. Willcox's apparent confirmation of our early statement that selenium in the absence of arsenic is not shown by Marsh's test, we would point out that according to our observations this is only the case when a lead acetate wash-bottle is used, whereby the small quantities of hydrogen selenide evading the precipitation on the zinc are retained as lead selenide. We were in the habit of constantly employing this wash-bottle as a precautionary measure[4] and hence the statement.[5] If, however, the lead acetate wash-bottle is not used it is possible to show even one-tenth of a milligramme of selenium by Marsh's test when using a capillary tube (small red ring with yellowish margin).

With regard to the identification of small quantities of selenium in organic fluids in the presence of larger quantities of arsenic by means of Reinsch's test we do not think that anyone not specially directing his attention to it could detect the selenium by microscopical examination of the sublimate, the crystals being for the most part badly defined. We have made many such experiments ourselves, but have relied upon the micro-chemical reactions of the dissolved sublimate for identification of selenium.

Our results have proved that selenium was present in two of the Manchester beers in poisonous quantities, but in neither case did the amount of it reach that of the arsenic. We therefore quite agree with the conclusions of Dr. Willcox that in the beers examined by him selenium was not present in amounts 20 or 10 times as great as the arsenic.

King's College, London, March 19th, 1901.

[1] THE LANCET, Feb. 2nd (p. 318), and 9th (p. 434), 1901.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF MALFORMATION.

BY W. R. H. STEWART, F.R.C.S. EDIN.,
SURGEON TO THE EAR AND THROAT DEPARTMENT OF THE GREAT NORTHERN CENTRAL HOSPITAL; CONSULTING SURGEON TO THE LONDON THROAT HOSPITAL.

THE little patient, who might justly be termed a pathological curiosity, was brought to the out-patient department of the Great Northern Central Hospital. The child had a double hare-lip, a double cleft palate (wide and extending the whole length), and a deep central ulcer on each cornea. There were half-a-dozen supernumerary auricles scattered about the face, the largest situated just below the left extremity of the lower lip and the remainder scattered about the left side of the face and neck. On the right side the ear was represented by a much enlarged lobule and a portion of the tragus. I could find no sign of meatus. There was

no opening through the soft tissues and no ridge or opening in the firmer structures could be felt. Having removed a portion of the pre-maxillary bone both sides of the lip were closed, the whole being done on three separate occasions. The space on the right side was very great, but it united very well. The child died on the day following the last operation, and unfortunately the body was allowed to be taken away without a post-mortem examination being made, so that the real state of the ear could not be obtained. The left ear was normal.

Devonshire-street, W.

A CASE OF LANDRY'S PARALYSIS.

BY ANDREW ROSE, M.B., C.M. ABERD.

ON Jan. 15th, 1901, my colleague, Dr. H. Osborne was called to see a youth, aged 18 years, who was taken suddenly ill while at work. He found him suffering from paralysis of the lower extremities. There was no history of any injury and his fellow workmen said that previously to his being taken ill he was quite well and was working as a fitter at his bench as usual. The first symptoms were that he felt cold and complained of acute pain in his back and right side and immediately afterwards he said that the "use went out of

his legs" and that they were like "pieces of wood." I saw him three hours afterwards at his home in much the same condition. He was unable to move either leg and complained of their icy coldness even after continued counter-irritation and warmth. I made a careful examination of the paralysed area which extended from an imaginary line on a level with the umbilicus downwards; the superficial and deep reflexes were abolished and no amount of pinching or pricking would elicit any symptoms of pain. Faradaic and galvanic currents were also applied and both gave negative results. A strong Faradaic current was passed through the muscles of each arm but they reacted sluggishly as also did those of the trunk. The mind was quite clear and the patient remarked that he was quite well if his legs were right. On my second visit 12 hours afterwards I found that the general condition was much worse and that he had had a restless night, but had partaken of a good deal of liquid nourishment. The heart showed signs of failing and the respirations were frequent and laboured. The interrupted current gave little or no response when applied over the muscles of the upper extremity, which showed that the paralysis was ascending. The patient was drowsy and listless but when roused he was quite sensible. Both pupils reacted sluggishly. There was nothing abnormal in the temperature. During the night he passed urine and fæces involuntarily. He died within 24 hours of the onset and was conscious to the end. At the necropsy none of the organs were found to present any pathological changes except the liver and spleen which seemed to be enlarged and mottled. The brain and spinal cord were apparently quite healthy.

This case of acute ascending paralysis is deserving of note owing to the sudden onset with no premonitory symptoms whatever and the very rapid course of the illness, also the absence of sensation over the paralysed parts. Bristowe, Taylor, and Westphal state that paralysis generally takes place in two or three days after the premonitory symptoms of weakness in the legs, that the course of fatal cases is from eight to 10 days and that the sensory nerves are scarcely if at all involved. I find that exposure to cold is put down as one of the causes of the disease. The morning of Jan. 15th was very cold indeed in Horwich and my patient was standing in a draughty part of the workshop, so it is probable that the low temperature was the initial cause in his case by bringing on a spasm of the spinal arterioles; or would the extreme cold act as a stimulant to some latent hereditary something and produce the paralysis? A sister of the deceased, who is now 30 years of age, has had paraplegia since infancy following acute anterior poliomyelitis. There might be some hereditary connexion. The rapid course of the disease would suggest the thought that there must be some infective toxic influence at work. Altogether the case has been a very singular one and it shows that much care should be observed in giving a prognosis in all cases of paraplegia. There were no symptoms whatever on the day preceding death that the case would have a fatal termination so soon.

Horwich, Lancs.

"A CASE OF PEMPHIGUS NEONATORUM IN AN INFANT THREE DAYS OLD."

By VICTOR J. HODGSON, L.R.C.P. LOND., M.R.C.S. ENG.

I WAS interested to read Dr. C. J. Glasson's communication in THE LANCET of March 9th, p. 697, having myself had a similar case last January. The patient was a full-time female child. On the morning of the third day I noticed that both eyelids had on them bullæ of the size of pigeon-peas, one on the right eye and two on the left. They contained a transparent fluid and were surrounded by a rose-coloured ring. There was very little exudation into the subcutaneous tissue of the eyelids, as shown by the absence of swelling. On the following day there was a fresh bulla of the size of a crown-piece on the abdomen near the umbilicus, and during the following week several more appeared, choosing for sites the fold of the groin, the outer parts of the thigh, and the nape and sides of the neck. The child seemed none the worse for this severe skin affection until from a week to 10 days from its onset, when either the contents of the bullæ had become pustular or the cutis had broken leaving a raw surface; then the child became restless, cried a good deal, and passed very offensive motions. On one occasion she had a fit. Eventually the trouble cleared off and the child was entirely free from blemish three weeks from the date of the first onset. There was no general desquamation. I feel sure that the condition was not due to syphilis because (1) I know the antecedents of both father and mother, the latter of whom has had no miscarriage, stillbirth, sore-throat, or loss of hair; (2) there is one elder child, aged three years, who is equally free from suspicion; and (3) the eruption did not appear on the soles of the feet, the palms of the hands, or the nates. The umbilical cord came away normally; there was nothing to suggest the possibility of infection by this channel. During the birth of the child I noticed that the eyes received a gush of amniotic fluid, and there was some delay in cleansing them. It is interesting in this connexion that the first appearance of the bullæ was on the eyelids. I am informed by a fellow practitioner that the child's cousin on the father's side suffered from a bullous eruption at an equally tender age.

BIRMINGHAM GENERAL HOSPITAL.

A SUCCESSFUL CASE OF EXCISION OF THE CÆCUM, VERMIFORM APPENDIX, AND PORTION OF THE ILEUM FOR CARCINOMA.

(Under the care of Mr. GEORGE HEATON.)

THE advance in recent years in the treatment of malignant disease of the large intestine has been very great. It is now only a few years since the palliative treatment of colotomy of one form or another was the only aid that surgery had to offer to the sufferers from this serious malady. The discomfort and annoyance resulting from colotomy were in many cases considered to be sufficient argument against its performance. Excision first replaced colotomy in malignant disease of the lower three inches of the rectum. At the present time complete removal of the growth is undoubtedly indicated in all cases where a diagnosis has been made sufficiently early, for the results are extremely good. A case in many respects resembling the one recorded below was published by Dr. Lowson of Hull in 1893.[1] The value of Murphy's button for intestinal anastomosis is still not acknowledged by everyone, but it may certainly be said that those who have used it much speak very well of it, while those who condemn it have in most cases not employed it on more than one or two occasions.

A delicate-looking anæmic woman, aged 53 years, was admitted into the Birmingham General Hospital on July 31st, 1899, suffering from abdominal pain and extreme weakness. The patient had never been very strong. Since her childhood she had always had some trouble with her bowels and had been habitually constipated. Three years before admission she began to have attacks of abdominal pain and the constipation and general irregularity of the bowels became worse. She had never passed blood in any quantity from the bowels but had been troubled latterly with hæmorrhoids. Eight months before admission she had a severe abdominal illness and was laid up in bed for several weeks with sickness and abdominal pain. Since that time she had rapidly deteriorated in general health and had lost weight. When first seen she weighed only 4 st. 8 lb. Her mother died from an internal cancer at the age of 72 years.

On admission the patient was extremely pale and sallow. She was very weak and feeble, especially on the least exertion. The conjunctivæ and mucous membranes were very pale. Her appetite was poor and capricious. The walls of the abdomen were lax. A large hard mass of about the size

[1] THE LANCET, March 25th, 1893, p. 648.

of a cricket-ball could be felt and seen in the right iliac fossa. It was irregular in outline and was situated about two inches from the right anterior superior iliac spine in a line between it and the umbilicus. The tumour seemed fixed to the abdominal wall but was somewhat moveable in the iliac fossa. It was tender on pressure and dull on percussion, and pain radiated from it across the abdomen. The bowels were opened irregularly, sometimes several times a day. The motions were loose and mixed with small scybala and covered occasionally with mucus. The temperature was raised slightly at night and she slept badly owing to pain. The heart and lungs were apparently normal. The urine was pale-coloured and small in quantity and contained neither sugar nor albumin. A diagnosis of malignant disease of the cæcum was made and it was decided to excise it if possible.

An operation was performed on August 11th. Chloroform was administered and the abdomen was opened by a vertical incision in the right linea semilunaris. The tumour, which was an enlarged cæcum, was adherent to the abdominal wall and a portion of this was cut away to free it. The cæcum, appendix cæci, and termination of the ileum were then dissected up from the iliac fossa. Two or three large branches of the ileo-colic artery were exposed by this dissection on the inner side of the cæcum and were ligatured. It was then possible to bring the cæcum with its appendix, the lower end of the ileum, and part of the ascending colon outside the abdomen through the operation wound. This was done and the peritoneum was carefully packed with sponges. The small intestine was then divided about three inches from its junction with the cæcum after previously clamping it with a Makins clamp. The ascending colon was then treated in the same manner about three inches up. The portions of ascending colon, cæcum, and small intestine between the clamps were then carefully dissected away from their remaining attachments, and after the ligature of a few remaining small blood-vessels were removed.

The ileum was then united to the ascending colon in the following manner. The cut end of the colon was closed by a continuous suture of its cut mucous membrane and a double row of interrupted Lembert sutures was passed through its serous and muscular coats. These sutures served the double purpose of closing the intestine and of arresting all bleeding from the cut blood-vessels. A short lateral incision was finally made on the inner side of the colon about an inch above its closed end and an anastomosis was made with the small intestine by means of a medium size Murphy's button. The intestine was then returned into the abdominal cavity, the sponges were removed, and the abdominal wound was completely closed by a number of silkworm-gut sutures passing through all the layers of the abdominal wall. The operation lasted in all an hour and 20 minutes. There was no shock and the patient's condition at its termination was very good.

The after-history was uneventful. The patient was fed per rectum for the first 48 hours, and was then given fluid nourishment by the mouth in gradually increasing doses. The bowels were opened naturally on the evening of the second day, and never afterwards gave any trouble. The wound was dressed for the first time on the seventh day, and was found to be soundly healed. The button was found in the rectum on August 24th, 13 days after the operation, and was removed. On the 27th the patient sat up for the first time, and was discharged convalescent on Sept. 15th wearing an abdominal belt. She has shown herself from time to time since, and is now in better health than she has been for some years. She has gained more than two stones in weight and is strong enough to manage a shop as she did before her illness. Her bowels act daily and medicine is rarely, if ever, required.

The cæcum with the growth is shown in the accompanying illustration, which is reproduced from a photograph. The tumour in the fresh state almost filled the lumen of the intestine and was greyish white on section with small blood extravasations in places. Microscopically it proved to be a typical cylindrical-celled carcinoma.

Remarks by Mr. HEATON.—The radical treatment of malignant growths of the large bowel by excision has lately had attention drawn to it by reports of successful cases by various surgeons. Barker, Paul, and McAdam Eccles have all lately published such cases. The case which has been related in the above abstract is a good instance of such an excision and shows the ease with which the operation may be done in a case not complicated by extensive adhesions and in which a diagnosis has been made before symptoms due to acute obstruction have supervened. Unfortunately at present it is only in a small percentage of cases of malignant disease of the large intestine that such

The cæcum laid open to show the growth.

extirpation can be undertaken or advised with much hope of success. The diagnosis is frequently arrived at only in a late stage of the disease when obstruction has already supervened or when the growth is already so advanced, or has involved neighbouring structures so extensively as to render its removal impossible. The surgeon can then only hope to palliate the patient's sufferings by establishing an artificial anus above the growth.

In cases where complete removal is possible it is at present a debated point whether it should be done in one or two stages. By the latter method the affected portion of bowel is first of all brought outside the abdomen and fixed there, the portion of it which contains the growth being subsequently excised. The patient is thus left with an artificial anus or is subjected to an operation for its cure. Theoretically, primary excision and end-to-end anastomosis constitute the better procedure, if the operation be performed before the onset of intestinal obstruction. But unfortunately the condition of the patient will frequently preclude the performance of so severe an operation and then we must be content to do the excision in two stages. For intra-peritoneal intestinal anastomosis in these cases there is no method, in my opinion, to compare with the use of a Murphy's button. The shock and severity of the operation by its use are much lessened because the anastomosis can be so rapidly performed.

CARDIFF INFIRMARY.—Three years ago it was decided to provide a gynæcological ward in the Cardiff Infirmary, and Dr. John D. Williams was appointed gynæcological surgeon. During the past two years the management committee have been compelled to lessen their expenditure and the women's ward was made to suffer until now Dr. Williams has only eight beds at his disposal, with an unoccupied ward of 20 beds which are empty from lack of funds for their support. Lady Windsor, Lady Aberdare, Mrs. Mackintosh of Mackintosh, and Miss Talbot have each undertaken to defray the cost of one bed and are appealing to the ladies of Glamorganshire for annual subscriptions of about £800 to enable the ward to be occupied completely and permanently.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Clinical and Pathological Features of Pernicious Anæmia, its Antiseptic and Serum Treatment.

A MEETING of this society was held on March 26th, Dr. F. W. PAVY, the President, being in the chair.

Dr. WILLIAM HUNTER made a communication on a case of Pernicious Anæmia with Observations on the Clinical Features, the Infective Nature, and the Antiseptic and Serum Treatment of the Disease. The patient (who was exhibited before the society) was a man, aged 37 years, whose symptoms—breathlessness, palpitation, and progressively increasing weakness—had come on very gradually two years before. The case had previously to coming under observation been regarded as a case of gastric catarrh on account of the discomfort in the stomach. The most prominent symptoms were a constant pain in the stomach and mouth, which was liable to exacerbations, coming on about every three weeks and lasting two or three days, after which the mouth and tongue became each time very sore and the tongue sore. The gastric symptoms consisted of pain in the stomach, nausea, and retching, which were worse when the organ was empty. A curious tingling and numbness of the fingers were complained of occasionally. The history was a very typical one as regards the oral sepsis, extending over eight or 10 years, followed eventually by gastric pains. The gradual onset of the anæmia with weakness and with recurrent attacks of gastric disorder and glossitis were also very characteristic. On admission there were four groups of symptoms—(1) weakness and extreme anæmia and their usual effects; the red corpuscles were only 27 per cent. of the normal and hæmoglobin only 35 per cent.; there was also poikylocytosis; (2) hæmolytic symptoms—viz., urobilinuria and a lemon colour of the skin; (3) oral and gastro-intestinal symptoms—viz., sore tongue, dental necrosis, suppuration of the gums at one part (which had existed for 10 years), and gastric pains; and (4) toxic symptoms—viz., tingling and numbness of the fingers and irregular pyrexia. The treatment consisted of oral and gastric antisepsis, the teeth were scraped, some were extracted, and a mouth-wash was used. Mercuric chloride was administered constantly. On July 9th, 13th, and 23rd three injections of anti-streptococcic serum were administered. After the first the red corpuscles rose to 36 per cent., after the second to 52 per cent., and in the course of three weeks the red corpuscles rose to 65 per cent., the hæmoglobin to 72 per cent., the hæmolysis (as evidenced by the colour of the urine) was arrested, and the patient's health slightly improved. The injections were followed by febrile reaction, that after the first was very marked. The temperature during the first week after admission had been variable, between 99° and 97·5° F., but after the injections it became steadier and about normal. The patient was so much better that he went for a time into the country. On Sept. 26th liquor arsenicalis was added to the other treatment. The improvement continued, the patient gained over one stone in weight, and on Dec. 20th the red corpuscles had risen to 94 per cent. and the hæmoglobin to 100 per cent. The only symptom remaining was occasional numbness in the fingers. The case, Dr. Hunter remarked, must be regarded as a typical one of pernicious anæmia in its mode of onset and clinical history and the four groups of symptoms present. The case was the first he had been able to treat on the lines he had recently recommended—viz., complete and long-continued oral and gastric antisepsis. These aimed at the removal of the infective cause of the disease and of the septic conditions of the mouth and stomach which favoured its operation. Nevertheless, the infection still remained on the tongue and showed periodic tendency to break out afresh. On several occasions the soreness of the tongue had returned, accompanied each time by feelings of illness and increased signs of hæmolysis in the urine, but each time they were checked by strong antiseptic measures. The results clearly showed the beneficial effects of serum treatment, at the same time confirming the infective nature of the disease. The first two doses were 10 cubic centimetres, afterwards 5 cubic centimetres were given. In view of the reaction it would be advisable in future to begin with only 5 cubic-centimetre doses and to see that the temperature was not variable and erratic at the time of the injection. Dr. Hunter illustrated his paper with lantern slides showing the clinical and pathological data of the disease and a schematic representation of the course and results of his investigations during the past 15 years.

Dr. CHARLES REISSMANN asked what changes in the blood enabled them to identify pernicious anæmia with certainty. He had seen two cases lately which showed all the clinical features of pernicious anæmia and which were so diagnosed during life, but at the necropsies colloid cancer of the stomach was revealed which had never been suspected. Poikylocytosis occurred also in other diseases—in leukæmia, for instance—though here the myelocytes and leucocytes enabled them to identify the disease.

Mr. T. J. BOKENHAM asked whether Dr. Hunter had really made out the nature of the specific infection. The only way to do this was by cultivation and he would like to know if this had been done. He had recently suggested that serum-therapy might be employed to stimulate the endothelial cells of the liver and the case brought forward seemed to be an instance of this. He also asked what anti-streptococcic serum had been used? But, he asked, how could anti-streptococcic serum mitigate the toxin of a staphylococcus? In making experiments some time ago he had observed that the toxin of certain specimens of staphylococci produced marked hæmolysis.

Dr. SIDNEY COUPLAND congratulated Dr. Hunter on the value of his researches which had thrown so much light on the disease and which would enable them to change its name. Pernicious anæmia was a hæmolytic process due to a specific poison which operated through the portal circulation. It still remained to isolate the special bacterium.

Dr. T. D. SAVILL, referring to the clinical aspect of pernicious anæmia, thought that slighter instances of the disease or of an allied disorder might prove to be more common than was generally believed. The original conception of pernicious anæmia implied an intense form of anæmia, occurring for the most part in elderly men, and almost necessarily leading to a fatal issue. Among the out-patients at the hospital were a large number who applied for neurasthenic and angio-neurotic symptoms, but who also presented marked gastric symptoms and very bad teeth. The cure of such cases rested largely with the dentist. He (Dr. Savill) had not made precise observations, but their skin was always pale, often "earthy" in colour; and it might be a question whether these were not instances of a toxæmia allied to pernicious anæmia.

Mr. ARTHUR BARKER remarked that these cases had considerable interest from a surgical point of view, and he thought that the blood of certain cases of alveolar abscess might profitably be investigated. The case described by Dr. Hunter he had seen and the intestinal symptoms obscured those referable to the mouth. He did not think that they sufficiently realised how much the state of the mouth could contribute to the production of disease of the intestine and stomach.

Dr. HUNTER, in reply, said that in the case he had referred to of alveolar abscess there was not the faintest suspicion of that lesion during life. He had since seen 10 cases exactly like the typical case of pernicious anæmia he had described. He wished to acknowledge the valuable work which had been done by previous observers in this field, such, for instance, as Addison, Pye-Smith, Sidney Coupland, Byrom Bramwell, and Sir William Broadbent. He (Dr. Hunter) wished to correct the impression, if such existed, that this disease was a gastro-intestinal dyspepsia. The alimentary tract was only the locality where the diseased process took place and it stood to pernicious anæmia just in the same relation as those of intestinal lesions stood to typhoid fever or those of the throat to diphtheria. As to the diagnosis of the disease, it was not to be based upon the blood changes alone but upon the association of these with four definite groups of symptoms—viz., anæmia, hæmolytic changes in the urine, oral and gastro-intestinal symptoms, and fever with other toxæmic symptoms. As to the separation and identification of the organism, the streptococcus was only an associated bacterium and it was not hæmolytic. He had not yet isolated the true specific organism.

MEDICAL SOCIETY OF LONDON.

Cases of Abdominal Injury with Rupture of the Viscera.—Lateral Sinus Pyæmia and Cerebellar Abscess with Cheyne-Stokes Respiration; Recovery.

A MEETING of this society was held on March 25th, Mr. JOHN H. MORGAN, the President, being in the chair.

Mr. THOMAS H. KELLOCK made a communication on three cases of Abdominal Injury with Rupture of the Viscera. In the first case the patient was a man, aged 40 years, who had been run over by an empty hansom cab the wheel of which passed obliquely across the abdomen from right to left. On admission to the hospital half an hour after the accident he was evidently suffering from severe internal hæmorrhage. The abdomen showed no mark of injury though it was tender all over and moved very little with respiration. The area of splenic dulness was thought to be increased downwards and there were a fracture of the ninth and tenth ribs on the right side and synovitis of the left knee. The abdomen was opened in the left linea semilunaris, blood was found in the peritoneal cavity, and the spleen was found to be extensively lacerated. (The specimen was shown.) On attempting to bring it forward free hæmorrhage took place which was controlled by seizing the pedicle and ligaturing it; a small piece of the spleen had been completely torn away and was removed separately. The patient rallied well after the operation, but on the second day symptoms of intestinal obstruction appeared. These did not yield to treatment and death occurred on the fifth day. At the post-mortem examination the ligature on the splenic vessels was found to be firm. There were superficial bruising of many of the viscera and complete obstruction of the small intestine a few inches above the cæcum owing to the bruising of this structure. The second case was one of ruptured kidney. The patient, a man, aged 32 years, had fallen from a height of about 15 feet, striking his left loin against the edge of a plank; on admission to the hospital he showed all the signs of internal hæmorrhage; he said that since the accident he had passed a quantity of blood by the urethra and the urine he passed soon after admission contained a large percentage of bright blood. He complained of pain in the back and abdomen and of a constant desire to defecate; the left side of the abdomen was very rigid and less resonant than normal, there were no external mark of injury and no good evidence of free fluid in the peritoneal cavity. When an anæsthetic had been given a large tumour could be felt in the region of the left kidney. The abdomen was opened in front as it was thought there might be injury to the intestines in addition to rupture of the kidney, but the other organs were found to be uninjured. The right kidney having been examined the abdominal wound was closed and the left kidney exposed from the loin. The lower third of the kidney had been completely torn from the upper two thirds, the rent opening the pelvis. The pedicle was ligatured and both pieces of the organ were removed, the wound being closed round a drainage-tube passed to the bottom of the cavity. The patient made an uneventful recovery. The blood in the urine ceased at once; he passed 47½ ounces of urine in the 24 hours following the operation, an average of 39½ ounces for the next nine days, and 64 ounces per diem for the next 13 days; then it became about normal in quantity. The third case was a woman, 55 years of age, who was knocked down by a hansom cab, one wheel passing across the abdomen just below the ribs. On admission to the hospital she showed very much the same signs of ruptured spleen as were noted in the first case. On opening the abdomen a quantity of blood escaped; the spleen was found to be much lacerated and torn away from its vessels; ligature of these and removal of the organ did not stop the hæmorrhage, and on further examination a rent of the liver, almost severing the left lobe from the right, was found. As the patient's condition was very bad this was rapidly plugged with gauze which seemed to stop the bleeding, but she did not long survive the operation. Attention was called to the fact that both the patients who sustained laceration of the spleen were injured by the wheels of vehicles proceeding at a fairly slow pace and to the fact that all the cases bore out the teaching that injuries to the front of the abdomen were likely to rupture organs loose in the peritoneal cavity, whilst those inflicted from the back injured organs more firmly attached to the parietes. The diagnosis of rupture of the spleen was considered briefly and the question of associated injuries when the diagnosis of rupture of one viscus had been made. In the first case the injury to the intestines was the cause of death. The treatment of injuries of this kind was considered. The only satisfactory way of dealing with hæmorrhage from a ruptured spleen was by removal of the organ and ligature of its vessels. Reasons were given for removing the kidney from the back. It was thought better to remove the whole organ rather than attempt to save the upper part, as the rent had opened the pelvis.—The PRESIDENT remarked that all such cases were most instructive. The methods of dealing with hæmorrhage into the peritoneum were comparatively modern. The reasons advanced by Mr. Kellock in this case for making first one incision in front and then removing the organ from the back carried conviction to his mind, but it was a question of opinion whether that procedure was correct.—Mr. F. C. WALLIS referred to three cases of rupture of the spleen which were not operated on until some time after the injury. They all got well. As regards the case of ruptured kidney he would like to ask why Mr. Kellock elected to operate; it would be instructive to learn what were the guides in such cases when there was no external wound. Again, what were the indications for immediate operation as compared with operation later? The usual course of such cases if left was that the kidney became septic from its propinquity to the colon, and finally the other kidney became infected through the urinary bladder and up the opposite ureter.—Mr. CUTHBERT S. WALLACE remarked that increasing dulness under the left hypochondrium was a valuable sign of ruptured spleen. One of the cases referred to by Mr. Wallis was not operated on for four days. As to the indications for operation it was well to bear in mind the general symptoms and particularly the state of the pulse, which was very important; for instance, if at the end of six hours the pulse was still very rapid. Reference was made to a series of cases collected by Mr. G. H. Makins in the "Annals of Surgery," 1899. These were practically all the cases of ruptured viscera at St. Thomas's Hospital, 1889–98—viz., 292 cases of abdominal injury, which included 88 cases of ruptured viscera. In only 21 (23 per cent.) there was ruptured intestine and in 35 rupture of the kidney.—Mr. KELLOCK, in reply, said that there were two indications for operation in his case of ruptured kidney. First, the amount of blood the patient was losing in the urine; and secondly, the constant desire of the patient to defecate and pain in the abdomen, which made him (Mr. Kellock) suspect injury to the intestine, a condition of even still greater gravity.

Mr. H. F WATERHOUSE made a communication on a case of Lateral Sinus Pyæmia and Cerebellar Abscess with Development of Cheyne-Stokes Breathing with Cessation of Respiration under Anæsthesia; recovery after two operations. The patient was a dental surgeon admitted into Charing-cross Hospital on April 17th, 1899, with lateral sinus pyæmia. He had been for many years a sufferer from chronic tuberculous abscesses in the region of the right hip and had had a purulent discharge from both ears for the greater part of his life. In 1895 Mr. Waterhouse had operated upon him for a large supra-mastoid abscess on the right side and shortly prior to admission Dr. Green of Wimbledon had opened two abscesses of the right hip. On April 11th the patient felt ill; the temperature was 100° F. and the pulse was 100. On April 12th he had a rigor in a train. On April 13th he had a rigor of half-an-hour's duration and a temperature of 103°. On April 15th Mr. A. M. Sheild saw the patient with Dr. Green and diagnosed lateral sinus septic thrombosis but was unable to decide upon which side the condition was. On admission to Charing Cross Hospital the patient's temperature was 104·2°, the pulse was 100, and the heart and lungs were normal. There were no pupillary changes and no optic neuritis. From this time to April 28th the patient had repeated rigors, the highest temperature was 105·2°, and a systolic heart murmur developed after continuous pain over the base of the heart whilst he was in hospital. Cough was noticed a few days later and the sputa was of prune-juice colour. His condition became profoundly toxæmic and apparently hopeless. Much valuable time was of necessity lost in waiting in the hope of determining upon which side the sinus was affected. At last, on April 28th, when it became clear that the time for operative interference with any hope of success was rapidly passing away, Mr. Waterhouse operated upon the left lateral sinus and internal jugular vein, dividing the latter between two ligatures and incising and clearing out the septic thrombus in the former. Recovery took place; nevertheless, on May 1st Dr. J. W. H. Eyre, bacteriologist to the hospital,

found streptococci in the blood. Everything went well until June 7th when the patient was allowed to get out of bed. On June 8th complaint was made of headache, vomiting occurred, and the pulse fell to 56. Drowsiness increased until on the evening of June 10th the patient was comatose and there were double optic neuritis, Cheyne-Stokes respiration, and a pulse of only 50. It was then decided to explore the temporo-sphenoidal lobe and the cerebellar fossa on the left side. Unfortunately, the former was first attempted with negative result. Respiration ceased entirely under even partial anæsthesia. Owing to the patient's condition vigorous artificial respiration had to be resorted to and the movement thus caused some laceration of the cerebral substance by the exploring needle. Soon the pulse ceased to be perceptible, and as the patient was obviously very near death the exploring syringe was made to perforate the tentorium cerebelli from above. Immediately an ounce of fœtid pus was obtained, the respiration and pulse recovering at the same instant. The left cerebellar fossa was now rapidly trephined and several drachms of pus were evacuated. Progress was henceforth most satisfactory, although there was for many days much word-deafness owing to injury to the temporo-sphenoidal convolutions. The patient was at the present time in better health than before his illness and was in full practice as a dental surgeon. Speech was nearly perfect; he could now manage a gas and ether extraction, comprising from 16 to 20 teeth and stumps, and could walk 10 miles in spite of his lameness. Mr. Waterhouse alluded to the extreme difficulty that had existed with regard to the decision as to which lateral sinus was affected and the hesitation he felt in risking operating upon the wrong side. He considered that the endocarditis having developed whilst the patient was under observation, and the presence of streptococci in the blood, proved it to be of pyogenic origin. He regretted that he had not at once, in the second operation, trephined for cerebellar abscess, but gave cogent reasons for acting as he had done. Remarks were also made as to the difficulty in locating intracranial abscesses and another case was related in which Mr. Waterhouse had first explored the cerebellum for an abscess which was situated in the temporo-sphenoidal lobe. This case fortunately also recovered.—The PRESIDENT remarked on the unusual and interesting features of this case which he had had the opportunity of seeing.—Mr. P. L. DANIEL remarked that this case pointed to the advantage of following a bold course even when the localising signs were very insignificant. Slight weakness of the left hand was the only indication in this case. As to whether the abscess was situated in the right cerebral or the left cerebellar lobe there was no real indication. The indications usually present in the jugular vein (pain and tenderness) were absent here. The case was a unique one. Recovery after such intense general toxæmia was very remarkable. The case threw some light on the functions of the cerebellum. It would seem that the hemispheres were quite subsidiary in importance to the vermis. In this patient the latter was the only part remaining.—Dr. G. L. EASTES wished to remark on the bacteriological aspect of the case. There was certainly a double if not a triple infection. In the first place streptococci were found in the blood; secondly, the pus was described as green, which probably indicated the presence of the bacillus pyocyaneus; and, thirdly, the pus was said to be "stinking," which probably indicated the presence of one of the anaerobic organisms.—Mr. WATERHOUSE, in reply, remarked that he quite agreed with Mr. Daniel. The chief difficulties in these cases were undoubtedly the slight localising signs present. He believed that they allowed cases to be lost because they waited for localising signs. He referred to two cases which he had recently seen in illustration. The first case died just before operation. In both cases an abscess on the temporo-sphenoidal lobes was discovered. The case under discussion undoubtedly had no left cerebellar lobe and the temporo-sphenoidal lobe was considerably injured; nevertheless, he was now managing a busy practice and he had no signs whatever of the damage to his cerebrum or cerebellum.

CLINICAL SOCIETY OF LONDON.

The Recent Epidemic of Typhoid Fever among the Troops in South Africa.

A MEETING of this society was held on March 22nd, Sir R. DOUGLAS POWELL, Bart., the President, being in the chair.

Sir WILLIAM BROADBENT, Bart., resumed the adjourned debate on the Recent Epidemic of Typhoid Fever among the Troops in South Africa. He remarked that the number of cases dealt with by Dr. H. H. Tooth was not sufficient to serve for an estimation of the incidence or of the severity of the epidemic, or for the establishment of points in the causation of the disease. This would only be possible when the statistics of the whole campaign could be made up. Statistics, however, required explanation and interpretation for which Dr. Tooth's work would be very valuable; he was a competent observer on the spot and his suggestions would serve for the guidance of others. Dr. Tooth thought that the infection was contracted at the Modder river, which apparently ran at one time in torrents and at another was a collection of stagnant pools, and which at the beginning of the epidemic was a sluggishly flowing stream. The interest of the epidemic, however, centred at Bloemfontein, where many efficient causes were probably in operation—namely, impurity of the local water, the sand, and the flies, together with contamination from person to person—which would not be possible in the well-regulated wards of a civil hospital. The prevalence of typhoid fever in India had also been explained as the result of dust and of flies. The latter should be collected wholesale and sent home for examination as to whether they were the carriers of contagion. In this country enteric fever was always considered to be water-borne, directly or indirectly (e.g., by watercress or oysters). Possibly they might have to revise their ideas as to the means by which the fever might be conveyed here also. With the troops there were antecedent predisposing conditions, such as (1) debility, overwork, and underfeeding; and (2) gastro-intestinal catarrh and derangements of digestion, both very common. With both of these sets of conditions they were familiar in this country and both might render persons susceptible who otherwise were not susceptible to the fever. The conclusion that diarrhœa and dysentery might favour the origin of typhoid fever was, he believed, proved; just as in this country influenza, in his opinion, opened the door to enteric fever in people who would not otherwise have it. Further, not only was the virulence of the enteric bacillus intensified by other toxins, but also through the exudation excreted by the enteric bacilli the mucous surface of the intestine became a nidus for other bacteria, the toxins of which aggravated the symptoms. There was in effect mixed infection, and occasionally the secondary infection was more serious than that of the original bacilli. Other important questions were, Did Europeans originally take the enteric fever to Africa, or did they find it there? Did it arise from local conditions without importation? and What was its incidence on the native races? He knew of no evidence on these points. As regards the type of the disease, Was South African fever exactly the same as ours? Professor Clifford Allbutt had said that there was no such thing as enteric fever; but there were individuals suffering from the invasion of special bacilli; that was so. In this epidemic in Bloemfontein there were individuals living under special conditions of overwork, but happily they had little or no access to alcohol which probably made the epidemic much less serious than it otherwise would have been. Again, there were no sewers or sewer gases in South Africa. The excreta of all kinds were exposed to air and sun, which had a destructive influence on bacilli of all kinds. The outcome of these two conditions should develop some peculiarities in the cases recorded. Had such peculiarities existed? Possibly such might be shown to exist when the cases were examined at the end of the war. In various epidemics in this country there were differences in the virulence of the poison. There were possibly varieties of the bacilli to which differences of immunity after previous attacks or after inoculation might be due. For example, a nurse who had worked through the Maidstone epidemic with impunity had afterwards enteric fever in this country, and subsequently went scathless through the epidemic at Bloemfontein; but later at Pretoria she developed an attack that nearly cost her her life. The immunity after her first illness apparently lasted only a little while. If he were proposing to be inoculated he would prefer to have the toxin prepared from the cases at the place of the epidemic to which he was going. He should consider it more efficient as a safeguard. He would refer only to two points in the symptoms and treatment. First, as to perforation. The indications that perforation had occurred were often not pain or local tenderness, but frequency of respiration and

of pulse. He had been called to cases in which the rapidity of the respiration was supposed to indicate the onset of pulmonary mischief, whereas it was a result of perforation. The respiration, too, was thoracic, not abdominal; in fact, he had never seen true diaphragmatic respiration in a case of perforation except when the patient was under the general influence of opium. In all cases of perforation large doses of opium might mask the abdominal symptoms. Secondly, as to the treatment of hæmorrhage he noticed that the successful issue was sometimes attributed to turpentine and hamamelis; but a morphine suppository was also used, and he believed that the quieting of the peristalsis of the bowel thereby produced was the cause of the success. When blood was poured into the bowel it promoted peristalsis, which again kept up the bleeding. In his judgment the most important point was to quiet the peristalsis by opium used in a suppository or given by the mouth. He had a great sense of the value of Dr. Tooth's paper, which would serve to draw the attention of future observers to many very important points in the disease.

Sir WILLIAM CHURCH, Bart., remarked that the Commission on which he served had been appointed to consider and report on the care and treatment of the sick in South Africa. It was no part of their duty to consider the causes of the epidemic of typhoid fever, and therefore he might not be able to add much that was of interest to the discussion. It had been alleged that the Commission had somewhat hurried the inquiry, but this was not so, though they had lost no time, because the country was anxiously awaiting their verdict. They had certainly worked very hard. Their first meeting took place at 3.30 P.M. on the very day of arrival at the Cape, and for 35 days, not excepting Sundays, they had carried on their investigations. He had asked many people their opinion about the value of inoculation, but the replies were so contradictory that it was impossible to form conclusions. He was personally inclined to think that it gave a certain amount of protection and had a certain modifying power. In a great many of the cases which he met with the inoculation had been only imperfectly performed. Dr. Tooth had stated that the Bloemfontein epidemic arose upon the Modder river. No mention had been made of Paardeberg, but his belief was that the chief source of infection was at Paardeberg. There the British troops had encamped below the Boer camp, and the river was full of dead carcasses. Laboratory experiments had shown that typhoid bacilli would live but a very short time in dry sterile sand; but they would live and retain their virulence in soil for at least 240 days. It was not decided whether the typhoid microbe was a sporulating bacillus or not. If it were the spores might remain potent for evil for an indefinite time. He believed it safe to assume that the bacilli were capable of living some time in dry dust. This enabled them to explain many features of the epidemic which could not be otherwise explained. For instance, it was a common thing to have cases at farms which had had no communication with towns or other possible sources for weeks at a time. He thought that the sand-storms might play an important part in conveying the disease. In the march from Paardeberg to Bloemfontein the clouds of dust must have been immense. He had not the slightest doubt that flies formed one of the readiest means by which typhoid fever was spread. Flies certainly congregated specially round typhoid stools; and on entering a hospital tent it was possible to identify which were typhoid patients by the way the flies congregated round the mouths and beds of those patients. Measures should certainly be adopted to prevent flies from spreading the disease. As regarded the clinical characters of the disease there were different causes which might render the disease more virulent. The type met with among the British troops was more virulent than that generally met with in South Africa. Many of the soldiers kept on duty while suffering from the disease and this helped to contaminate a larger area. The thirst produced by exertion in the hot sun was almost intolerable, and no wonder the soldiers were injudicious. It was often very difficult to obtain fuel for the boiling of water. Turning to the question of preventive measures these must, of course, depend on sanitation. Typhoid fever had always been prevalent in armies since its distinction from typhus fever. The difficulties in South Africa were considerable, especially in obtaining good water. The Modder could often be crossed without wetting the shoes, and with regard to many other rivers it was the same; and the water at this time had a pea-soup character which clogged any and every filter. He did not know why more attempts had not been made to establish Abyssinian wells. Formerly a sanitary officer had been attached to the headquarter staff of each division. This official had been done away with. There was a universal opinion that there ought to be a sanitary officer. Lord Roberts had appointed someone in that capacity at Bloemfontein, Johannesburg, and Pretoria, but this was not quite the same thing. It was extremely desirable that there should always be a medical officer of health at any large standing camp who should work in harmony with the military surgeons and should be also responsible for the space intervening between that and the neighbouring camp.

Brigade-Surgeon-Lieutenant-Colonel ALEXANDER CROMBIE, I.M.S. (retired), gave the statistics of 150 consecutive cases of convalescence from enteric fever which he had seen between September, 1900, and January, 1901, in the persons of British officers, who had contracted the disease in South Africa. Of these officers nine, or 6 per cent., had had a previous attack of enteric fever. In one instance the first attack occurred in May, 1900, in Bloemfontein. The patient came to England to recruit his strength, returned to South Africa in September, and had a second attack in November. After each attack his blood responded strongly to Widal's test. In another instance the patient had enteric fever in India in November, 1899, and a second attack in South Africa in August, 1900. The longest interval between the first and second attacks was three years. Of the 150 officers 13, or 8·7 per cent., had relapses; 38, or 25·3 per cent., suffered from thrombosis of the veins of one or both legs, to a greater or less extent; and 48, or 32 per cent., from bowel irritation during convalescence, sometimes very persistent, and constituting, after thrombosis, the most frequent obstacle to an early return to duty. One officer was still under treatment in a nursing home, 11 months after the attack of enteric fever. In this case Dr. Crombie had satisfied himself that the bowel irritation was due to muco-colitis. In another instance the patient continued to be troubled with similar symptoms 10 months after the attack. The other more frequent sequelæ were cardiac debility, peripheral neuritis, and periostitis. Of these 150 officers, 77, or 51 per cent., had been inoculated once, 6, or 4 per cent., twice, and 58, or 38 6 per cent., had not been inoculated. Except as regards relapses inoculation did not seem to have influenced either the frequency or severity of any of the sequelæ. Of those not inoculated 12 per cent. had relapses, while only 6·5 per cent. of the protected suffered from them. There was no reasonable ground for anticipating that the sequelæ would be modified by inoculation. Dr. Crombie then called attention to the remarkable features which distinguished the recent South African epidemic from all previously recorded ones—namely, the frequency of second attacks, the unprecedented number of cases of thrombosis, and the prevalence of subsequent muco-colitis during convalescence. Besides these features another was the extraordinary profuseness of the rash; in many cases it appeared to have been thickly distributed not only all over the trunk but also over the extremities. These South African cases offered in these respects a marked departure from ordinary epidemics and especially from what he had elsewhere described as "bastard typhoid," a form frequent in India, running a mild course of three weeks' duration without rash, diarrhœa, complications, or sequelæ. The South African cases would seem to indicate either special virulence of the bacillus typhosus, a supposition negatived by the low mortality, or that they arose from a mixed infection. In support of the latter view he quoted the recent experiments of Remy who had shown that when Eberth's bacillus was cultivated in vitro along with the bacillus coli communis their respective characters were intensely modified, the latter losing its power of forming indol and fermenting glucose, while Eberth's bacillus acquired the power of resisting its own antitoxin. This was consonant with the observations of Sanarelli, who had found the virulence of the bacillus typhosus greatly enhanced by the simultaneous injection of the bacillus coli communis into the same animal. Major R. H. Firth's observations were also of interest in this connexion. He found that several cases of "typhoid" fever in India were due to infection by the bacillus enteritidis of Gaertner, while the serum of others reacted to other members of the coli group more closely allied to the bacillus coli communis. The South African epidemic seemed to indicate the necessity for a reconsideration of the whole question, and if it should come to be admitted that the varying clinical picture raised by the word "enteric" was due to a mixed

infection it would be ranged along side of that other clinical picture which was called "phthisis pulmonalis," which was also the result of a mixed infection.

Captain W. A. WARD, R.A.M.C., expressed the conviction that flies played a prominent part in spreading the disease. The 19th Hussars, a regiment to which he was attached, was a seasoned regiment, yet it was the first to develop enteric fever in Ladysmith and suffered very extensively. The men had not been inoculated. The water-supply could not be suspected. In the neighbouring camp was the Liverpool Regiment which was next attacked; and next to this was the Naval Brigade, which was attacked third. On investigation he found that some years ago an enteric fever camp had existed on that spot. The ground was always black with a mass of flies which invaded the food. The clinical type of the disease differed from that met with in England. The advent was very sudden in nearly all the cases, the pain in the head was very acute, and the rash was peculiar. It appeared from the sixth to the eighth day, and was very profuse indeed, though it had no relation to the severity of the attack. A case was quoted in which the temperature suddenly fell when the rash came out. The temperature was often of an intermittent character. As regards preventive measures it could not be realised at home what great difficulties there were to contend with. The disposal of the dead needed reformation, and in his opinion cremation should be adopted. All the places where typhoid fever patients had been superficially buried would form future foci. The subject of inoculation must be approached with great caution. There would be great difficulty in compiling statistics. They would not go far enough or show sufficient particulars, and natural and acquired immunity also had to be considered. Personally he was inclined to believe that cases after inoculation had milder attacks and that the mortality was less.

Dr. A. P HILLIER wished to refer to the question of the multiplicity of infection. It must be remembered that in these tropical countries there was a definitely milder type of the disease, and that there were a number of unclassified fevers in the tropics. Cases of simple continued fever might last from three or four days to three or four weeks. He would like to ask what were the points of distinction between typhoid fever and simple continued fever. In his belief typhoid fever was more usually conveyed by dust than by water. In Kimberley, where he practised for seven years, typhoid fever recurred each year about the same time, in the summer and autumn. The water-supply was above suspicion. The pail system of closets was in vogue. This night service was generally done carelessly, and thus the disease was spread by dust. Filters and boiling of water did not render water innocuous. He could fully support the idea of a sanitary officer attached to each great standing camp. He deplored the death of Captain M. L. Hughes, R.A.M.C. But why was only one bacteriologist appointed? Why not half-a-dozen? Was it not also expedient to consider whether the Army Medical Department might not be supplemented, not only from the rank and file of the profession, but also from among physicians. He thought that it would have been a most desirable thing to have sent out several leading physicians.

Dr. P. HORTON-SMITH remarked that it was abundantly clear from what had been said that the common soldier would not allow his water to be boiled or filtered before drinking. It was important, therefore, to exercise more care in the disinfection of the excreta. This was done during the war with extreme care and most admirably as regards the fæces, but less care was exercised as regards the urine, which from the myriads of bacilli often present in it was the more important. The observations made by himself as to this point had been lately fully confirmed in Professor Koch's laboratory in Berlin and also by Professor Petruchsky of Danzig. This important fact might be fully accepted. How, then, should they guard against the danger involved in the urine? They might add antiseptics to it after it was passed, but this, considering the large quantities to be dealt with, was almost impossible. Far better if they could sterilise it in the bladder before it was passed. Fortunately this could be done by the use of urotropin (hexamethylen tetramin) in doses of 10 grains three times daily. As had been shown by Richardson of Boston and himself and recently confirmed in Professor Koch's laboratory, no person came to harm from such treatment beyond occasionally a little pain on micturition, a condition which could be obviated by omitting the drug for a day or two or by diminishing the doses. He had taken the drug for six weeks in 10-grain doses three times a day with no ill-effects beyond occasional slight dysuria. The urine never became albuminous. There was much danger in the urine in cases of typhoid fever.

Dr. ARTHUR LONGHURST remarked that there were many different types of typhoid fever. The disease in hot climates was more severe and fulminating than in cold and dry climates, which tended to destroy the disease. The typhoid bacillus could apparently remain dormant for a considerable time in the system and then suddenly break out, much in the same way as the malarial microbe did. The disease was more successfully treated in a tent than in a hospital.

Dr. H. H. TOOTH, in reply, thought that it was to be regretted that the post of sanitary officer had been abolished; he believed that there was room for such an official and even for a sanitary corps, and that officer should be vested with considerable authority. As regards inoculation, Professor Wright had said that the dose should be adjusted to the individual. He would like to know how that could be done? He (Dr. Tooth) confirmed the statement that the typhoid fever patients in a ward could be identified by the flies which hovered over and settled upon them. He thought that when once a man contracted typhoid fever he should not be allowed to rejoin the forces during that campaign. As to the nature of simple continued fever—many of these cases were fever of exhauston—some of them were mild cases of a fever *sui generis*, but the larger number of cases were undoubtedly typhoid fever, and gave the Widal reaction. One observer had found that 75 per cent. of cases of simple continued fever gave the Widal reaction. As a disinfectant urotropin did not meet the case of those who were walking about the camp; the patient had to be in bed while under the treatment.

OPHTHALMOLOGICAL SOCIETY.

The Evolution of the Colour-sense.—Peritomy in Episcleritis, Iritis, Herpes Ophthalmicus, and Purulent Ophthalmia.—Membranous Conjunctivitis.—Hypertrophy and Ossification of the Tarsus.—Note on the Surface of the Normal Cornea.

AN ordinary meeting of this society was held on March 14th, Mr. G. ANDERSON CRITCHETT, the President, being in the chair.

Dr. F. W. EDRIDGE-GREEN read a paper on the Evolution of the Colour-sense. He said the facts of colour-blindness threw a good deal of light on the evolution of the colour-sense. Cases of colour-blindness might be divided into two classes, quite separate and distinct from each other, though both might be present in the same person. In the first class there was light as well as colour loss. In the second class the perception of light was the same as in the normal sighted. Many colour-blind persons belonging to this class had a light perception much more acute than was found with most persons having a normal colour perception. Colour-blind individuals belonging to this class could be arranged in a series. At one end of this series were the normal sighted and at the other end the totally colour-blind. Dr. Edridge-Green had classified them in accordance with the number of colours which they saw in the spectrum as pentachromic, tetrachromic, trichromic, dichromic, and monochromic. All the facts which could be gained from the study of museums and literature pointed to the view that the sense of light was developed first and then the sense of colour, those waves which differed from each other most physically being first perceived as different—namely, red and violet. It was obvious that if a certain portion of the visual centre were set apart for the perception of colour, when it was very small and ill-developed it would only be able to perceive differences of considerable magnitude; but as more cells were added to the centre greater and greater power of perceiving differences arose. Each cerebral cell might at first have been connected with many optic nerve-fibres, and the number gradually diminished as evolution proceeded. It need only be assumed that the nerve impulses differed in quality—for instance, in wave length—just as the waves of light differed physically in wave length, and that when a nerve impulse of a certain character acted on a cerebral cell it gave rise to a corresponding sensation of colour within the range of perceiving differences possessed by that cell. It was obvious that if the nerve impulses did not differ in quality one could never have a sensation of colour. The spectrum was therefore first seen as grey, then

with a tinge of red at one end and violet at the other. As the colour sense developed it was not necessary that the rays should be so far apart before a difference was seen, and so the grey band gradually diminished until it entirely disappeared and the two colours met in the centre of the spectrum. A third colour, green, then appeared at the central point. Then yellow appeared, making four colours; then blue, making five; and finally orange, making the normal six. In some persons evolution had proceeded further and seven colours were seen, there being two colours between the green and the violet instead of one. It was found that paintings were first monochromatic, then red and violet were used as colours, then green, then yellow, and then blue. Homer's colour vision was of the degree just preceding total colour blindness. The description by different authors of the rainbow as having one, two, three, four, five, six, or seven colours was very characteristic. These facts showed that colour blindness was only an example of an earlier state in the development of the colour-perceiving centre.—The paper was discussed briefly by the PRESIDENT, Mr. JOHNSON TAYLOR, Dr. E. H. CARTWRIGHT, and Dr. J. H. PARSONS.

Mr. T. PRIDGIN TEALE (Leeds) read a paper on Peritomy in Episcleritis, Iritis, Herpes Ophthalmicus, and Purulent Ophthalmia. Under the name of syndectomy or *tonsure conjunctivale* this operation was introduced by Furnari of Paris for the treatment of panniform and chronic lesions of the cornea and for vascular ulcerations and interlamellar opacities.[1] The first notice in English literature was an article on Syndectomy by Mr. Bader in the Ophthalmic Hospital Reports, vol. iv., p. 109, for 1863, in which the author gave copious extracts from the original papers. Syndectomy was, as its name implies, an excision of a strip of conjunctiva and sub-conjunctival tissue denuding and exposing a ring of sclera round the cornea one-third of an inch in width. It was discovered that this sacrifice of conjunctiva was unnecessary and might at times be an actual disadvantage, so that peritomy came in as a substitute. By peritomy was meant the laying bare of about one quarter of an inch of the sclera immediately around the sclera by scissors and the division of all the vessels in that area which entered or emerged from the sclera without any cutting away of tissue. This separated conjunctiva in some cases reunited so rapidly with the denuded surface and corneal margin that in severe cases it was well to make two, three, or four radial cuts into the free edge of the conjunctiva so as to retard union and secure a more distinct cicatrix as a means of cutting off and constricting the vessels. The late Mr. Hewetson called their attention in Leeds to the remarkable effect of syndectomy or peritomy on the diffuse keratitis of inherited syphilis—an effect Mr. Teale fully endorsed from practical experience, and he wished now to produce evidence of its value in episcleritis, iritis, herpes ophthalmicus, and purulent ophthalmia, and to raise the question of its possible use in rare cases for the relief of tension. In episcleritis, a most painful and intractable affection, the immediate effect of peritomy in the relief of pain and suffering were marked, and in the three cases so treated considerable advance towards recovery in the local condition had taken place in the succeeding two to five months. In iritis of an obstinate character, whether syphilitic or otherwise, similar effects were noted; and in the three cases recorded immediate relief of pain was followed by steady improvement in the local appearance and vision in the course of a fortnight. There were probably few affections of the eye which were more unmanageable and more to be dreaded than the ulceration of the cornea and congestion of the conjunctiva which were associated with herpes. In two cases treated by peritomy the pain rapidly subsided, and in the course of a week or 10 days the healing of the ulcerated cornea and clearing of the inflamed iris were well advanced. In a case of sub-acute purulent ophthalmia originating in congenital infection of several days' duration and presenting marginal ulceration of the cornea and opacity completely obscuring the pupil peritomy was performed, and with such benefit to the eye that the degenerating process was at once arrested and in a week the child was sufficiently recovered to return home. When seen six months later it was difficult to detect which had been the affected eye. As an example of the utility of peritomy in the relief of tension the following case was cited. A woman had lost the right eye from irido-cyclitis accompanied by increased tension which an iridectomy by a skilled ophthalmic surgeon had failed to arrest. Subsequently the eye was excised. She had an insuperable dread of an iridectomy in the other eye which was beginning to suffer in like manner, with the tension + 2, vision reduced to Jaeger 14, and a partially inactive pupil. Peritomy was performed on Sept. 26th, 1900. On Oct. 5th there had been steady improvement: vision Jaeger 8, Tension + ½. On Nov. 26th vision had fallen off. Tension was normal. Later still vision was reduced to perception of large objects. In this case peritomy checked for a time the disorganising process and reduced tension but did not permanently arrest the mischief.—The PRESIDENT referred to a paper and cases by the late Mr. George Critchett who usually removed a strip of conjunctiva about one-sixth of an inch wide down to the sclerotic in cases of pannus and vascular ulcer, without any bad results. He (the President) would now add episcleritis to the list.—Mr. MARCUS GUNN recommended that the conjunctiva should be divided as near the margin of the cornea as possible and then separated from the sclerotic by a few snips of the scissors.—Dr. CARTWRIGHT thought the explanation offered could not apply to episcleritis, scleritis, or high tension. In such cases the treatment was more of the nature of counter-irritation.—Mr. H. SECKER WALKER (Leeds) spoke of the good results obtained in interstitial keratitis. There was no great change produced in iritis and the method was probably of least value in episcleritis. No cicatrix was visible after peritomy.—Dr. JOHN HERN (Darlington) preferred curetting the conjunctival incision down to the sclera; he had obtained excellent results in interstitial keratitis and much benefit in episcleritis. The operation was undeservedly neglected.—Mr. JOHNSON TAYLOR and Mr. J. H. CROPPER also spoke.

Dr. J. F. BULLAR described a case of Membranous Conjunctivitis. The patient was a child who was born on Oct. 28th, 1900, and who was quite well when seen on Nov. 5th. On Nov. 7th the right eye was noticed to be affected and was treated by the nurse until Nov. 11th, when it became much worse, and a medical man was called in. When Dr. Bullar first saw it the lids were very much swollen, a yellowish membrane was present, which stripped off very easily with scarcely any bleeding. Nitrate of silver, two grains to the ounce, was used. The eye got better and the chemosis subsided, leaving a small central ulcer of the cornea. There was difficulty in sucking. Membrane was also noticed on the right side of the nose and fauces which extended. The child died in convulsions on Nov. 20th. There was no diphtheria in the neighbourhood and the membrane was not examined.—Mr. SYDNEY STEPHENSON made it a rule to use antitoxin on first seeing a case without waiting to verify the diagnosis bacteriologically.—The PRESIDENT said that Mr. Tweedy, who had had great experience in these cases, looked upon quinine as being a specific in diphtherial conjunctivitis, and he had himself seen great benefit from its use.—Mr. W. LANG thought that Mr. Tweedy's observations had been made long before antitoxin was known, and he thought it should not go forth as the opinion of the society that this view was still held.—Mr. C. DEVEREUX MARSHALL said he should not think of waiting to conduct a bacteriological examination (though this would not take long), but in a case of supposed diphtherial conjunctivitis he should at once inject antitoxin, which in no case could do harm, and in a true case the sooner it was given the better. With regard to the local application of quinine he strongly approved of it, though he had not seen its use followed by such excellent results as those obtained by Mr. Tweedy.

Two papers by Major H. HERBERT, I.M S., were taken as read. The first was on Hypertrophy and Ossification of the Tarsus. A male Hindu, aged 33 years, had considerable enlargement of both upper tarsi, especially towards the outer ends, without much thickening. On the left side it was fibrous, but on the right there was considerable bone formation, which was fairly dense. A piece of necrosed bone exposed on the conjunctival surface of the lid kept up irritation, for which the patient sought relief.—The other paper was a note on the Surface of the Normal Cornea. Over 30 normal corneæ were examined in Bombay, all of which showed more or less epithelial defect when the surface was partially dried by exposure, the upper lid being elevated from the eyeball, focal illumination and the corneal bi-convex lens being used. In some cases there were only one or two pits seen, in others many closely-set pits, in others grooves added, and in others one or more large depressed patches.

[1] Gazette Medicale, 1862, Nos. 4, 6, 8, 10, 12, and 14.

The depressions were all sharply defined and their floors stippled owing to the irregular surface presented by the deeper epithelial cells. They usually began to appear within half or one minute, sometimes within a few seconds, but were generally not fully shown for two or three minutes. Repeated exposures and the instillation of cocaine sometimes caused an extensive irregular superficial exfoliation of the epithelium, which partly obscured and altered the original picture. The patients examined were all native, mostly adults. Slight conjunctivitis and localised keratitis tended to exaggerate these physiological defects. In superficial punctate keratitis some of the points stained with fluorescine appeared depressed on drying and had to be distinguished from the physiological pits above described, possibly to be seen on the same cornea.

The following cases and card specimens were shown:—

Mr. G. HARTRIDGE: (1) A Capsulotomy Knife; and (2) a case of Central Choroiditis simulating a Neoplasm which had been watched for 14 years.

Mr. H. SECKER WALKER: A Diagrammatic Model to assist in the Teaching of Refraction.

Mr. J. H. TOMLINSON: A New Colour Perimeter.

Dr. J. H. PARSONS: Coloboma of the Optic Nerve.

Dr. G. W. ROLL: Immobility of the Pupils with Fundus Changes.

Dr. P. FLEMMING: Section showing Dilated Nerve Fibres in the Retina.

Mr. R. W. DOYNE: A Simple Form of Ophthalmoscope.

Mr. WORK DODD: A case of High Hypermetropia.

CHELSEA CLINICAL SOCIETY.

Discussion on the Clinical and Pathological Relations of the Chronic Rheumatic and Rheumatoid Affections to Acute Rheumatism.

THE adjourned meeting of this society for their annual Clinical Debate was held on March 19th, at the Jenner Institute of Preventive Medicine, the President, Dr. WILLIAM EWART, being in the chair.

A paper entitled "Some Remarks on the Relationship between Acute Infective Rheumatism and Rheumatoid Arthritis," by Dr. G. A. BANNATYNE of Bath, was read. The communication began by contrasting the ordinary symptoms of a case of acute infective rheumatism with those in a case of rheumatoid arthritis. Once seen the acute forms of these diseases could, he said, never be confused. What was to be said about those rare cases which commenced apparently as moderately acute attacks of infective rheumatism, but which refused to respond to treatment and which as time passed gradually became more and more distinctive of rheumatoid arthritis? How were those cases to be classed which after several attacks of acute infective rheumatism developed rheumatoid disease? Were they mixed infections or did the rheumatoid infection become ingrafted upon the infected rheumatism? Dr. Bannatyne's theory was that those cases were instances of rheumatoid arthritis ingrafted on an attack of acute infective rheumatism. Statistics showed that rheumatoid arthritis frequently followed other diseases, but did not show that it followed acute infective rheumatism with much greater frequency than it did any other joint trouble. The chronic variety of rheumatoid arthritis followed altogether a different course to the acute forms and might well be secondary degenerations following on any acute joint trouble. Dr. A. S. Wohlman and he had found a micro-organism in one form of rheumatoid arthritis, but the micro-organism found by Dr. F. J. Poynton and Dr. A. Paine differed from that one in character and in life-history. Dr. Bannatyne concluded that the two diseases in the acute stages were quite separate and distinct. The hereditary tendency to joint troubles was marked in rheumatoid diseases, but it might be that it was gout and not rheumatism that was inherited.

Dr. R. T. HEWLETT said that in the only case of acute infective rheumatism in which he had examined the fluid he had isolated a bacillus which resembled the Achalme bacillus. He thought that the organism which Dr. F. R. Blaxall had isolated was quite distinct from that found by Dr. Poynton and Dr. Paine. It had to be remembered that identity of clinical symptoms and nearly identical pathological lesions did not necessarily prove identity in etiology. The toxæmias had a great predilection for the joints and arthritis was seen in scarlet fever, influenza, dysentery, yaws, verruga permana, and Malta fever. He agreed with Dr. Bannatyne that the rheumatoid condition was grafted on to the rheumatic one.

Mr. W. ARBUTHNOT LANE said that he found that the term "chronic rheumatic affection" of a joint was used to comprise the conditions of joints in which there was pain of a rheumatic character unaccompanied by any marked change in the anatomy of the joints except, perhaps, some effusion into them. The most marked feature of chronic rheumatic affections of the joints was pain, often variable in amount and influenced greatly by the weather. If this were the case there were innumerable traumatic or mechanical conditions which exhibited precisely those symptoms which he saw usually diagnosed and recognised as chronic rheumatism or, if there were distinct joint changes, as rheumatoid arthritis. The student was taught, and perhaps was still taught, that rheumatoid arthritis or osteo-arthritis denoted a disease of a joint which commenced in the articular cartilage evidenced first by a change in it and later by its removal. But he (Mr. Lane) believed that these cases comprised a large number of conditions or variations in the anatomy of the skeleton produced by traumatism. These conditions had no relation whatever to acute rheumatism, nor were they, as far as he knew, related to any chronic rheumatic affection, while, on the other hand, their causation was most clear and precise, being simply mechanical. He regarded the terms "chronic rheumatic" and "rheumatoid" affections, apart from true rheumatoid arthritis, as unmeaning terms and used too often as useful cloaks for ignorance.

Mr. WILLIAM ARMSTRONG (Buxton) read a paper which dealt more especially with the Etiology of Chronic Rheumatic and Rheumatoid Affections. He could not accept the conclusions of Dr. Poynton and Dr. Paine that micro-organisms were the sole factors in the causation. The man who whenever he got his feet or clothes damp felt stiffness behind the angle of the jaw, followed, if that was not arrested, by tonsillitis and rheumatism, could not be looked upon, in the opinion of Mr. Armstrong, as suffering from the effects of a specific germ. The fact that there was a specific form of acute rheumatism did not justify them in putting all acute rheumatic cases down to the credit of that factor. Dr. Poynton and Dr. Paine did not say whether the cases were acute or chronic in which they had found the diplococcus. He had rarely been able to connect chronic manifestations of rheumatism with the acute form of the disease. It had been suggested by Dr. W. M. Ord that in addition to the toxic factor there was a neural one caused by irritation conveyed to the spinal centres through the agency of the nerves of the prostatic urethra in cases of gonorrhœal rheumatism. He was convinced that one form of rheumatoid arthritis did sometimes follow acute rheumatism, but he had never seen it come on unless the patient had been much debilitated or worried. Although he had gone into the matter most closely he could not confirm Dr. Hawthorne's observation that there was in any considerable number of rheumatoid patients a family history of rheumatism. He did not think that in Mr. N. C. Macnamara's cases the result was due to direct infection of the joints by means of absorption of morbid material. Certain tracts in the spinal cord were greatly influenced by utero-ovarian irritation, and many cases were on record where arthritis lingered on until this source of irritation was eliminated. Mr. Armstrong quoted cases to show that other toxins were capable of causing arthritis. It seemed to him probable that while the more serious joint lesions, such as Charcot's, were really due to organic lesions in the cord the slighter changes causing arthritis were probably only functional. The bacillus discovered by Dr. Bannatyne, Dr. Wohlman, and Dr. Blaxall in rheumatoid joints had not as yet reproduced arthritis on injection, although a somewhat similar micro-organism was alleged to have done so in the hands of German investigators. In conclusion he submitted that it was certainly improbable that all rheumatoid arthritis was due to a bacterial factor; that it seemed likely that the disease was a dystrophy dependent either upon central nerve disturbance or upon reflex irritation transmitted to the joint centres from some other organ; that the irritation was very apt to be directed towards any joint already affected by rheumatism or gout; and that acute rheumatism was occasionally

followed by a form of rheumatoid arthritis, but as far as present knowledge went there was no common origin of acute infective rheumatism and of the more chronic joint conditions which they were discussing.

Dr. ALEXANDER PAINE said that if the symptoms spoken of by Mr. Armstrong were rheumatic in the sense of acute rheumatism it was quite consistent that such symptoms might be due not necessarily to the prevalence of the organism but of its toxins. He could not speak definitely on the toxins because very little was known of the organism; it was not until the toxins had been isolated that it would be possible to give any definite opinion and to say what symptoms were actually due irritatively to the presence of the organism and what was due to the action of the toxins. He reiterated that it was possible that many of the symptoms that came on even before the sore-throat might be ascribed to the absorption of toxins.

Dr. BLANC (Aix-les-Bains) said that some people were of opinion that rheumatoid arthritis arose from special toxins or from particular foods, but it seemed to him that it came from other troubles which they did not know of. At any rate, it was a disease of long standing, and it was difficult to reconcile that with a toxic condition. There was a special kind of chronic rheumatism which had nothing to do with rheumatoid arthritis; it certainly very often might be a consequence of true rheumatic fever, but just as often rheumatic fever was a different disease.

Dr. ARCHIBALD GARROD, in summing up the discussion, briefly passed in review the remarks which had been made by the different speakers in the debate. In his opinion the diplococcus of Dr. Poynton and Dr. Paine actually brought them to the pathological cause of acute rheumatism and it served as a criterion to differentiate acute rheumatism from other affections. Dr. C. O. Hawthorne had taken up a judicial standpoint and had urged that we must not dismiss as worthless the opinion that rheumatoid arthritis was a continuation of rheumatic fever because it did not happen to be the prevalent opinion at the present moment. Though Mr. Arbuthnot Lane had spoken on the question of traumatism he understood that Mr. Lane himself differentiated quite distinctly the more acute forms of multiple rheumatoid arthritis. They were only beginning to learn something about the conditions grouped together under the term "rheumatoid arthritis."

Sir DYCE DUCKWORTH then delivered the closing address of the debate. He said that he must be a bold man who in the first year of the Twentieth Century attempted to find a new niche in nosology for the condition recognised as rheumatoid arthritis. The difficulty of the subject was recognised by all and no less the confusion that still existed respecting the varieties of arthritis which led to deformity. Increasing knowledge and exactness compelled them to recognise that by far the greater number of "pains" met with were not truly rheumatic but owned a different pathogeny. For an accurate conception of the conditions recognised as true rheumatoid or osteo-arthritis it was necessary to state concisely what was known respecting true rheumatism and its influence on the joints, and also what was known of the effects of gouty influences on these structures. The doctrines of the diatheses were commonly believed to be buried in old books and regarded as the mediæval lucubrations of pedantic physicians who groped in the dark days before microscopes and more precise clinical methods were introduced. Such was not his view. He had learnt to satisfy himself of the truth and importance of some of those doctrines and was therefore in accord with the teaching of the French school in respect of a specific diathetic habit of body which was specially vulnerable to such peccant matters as generate rheumatism, gout, and some other ailments, and prone to react specifically in respect of the component structures of the joints. Exostoses were specially significant in gouty arthritis and many truly gouty deformities of joints were by themselves indistinguishable from those induced by rheumatoid arthritis. Occasionally an exact diagnosis was impossible, but in rheumatoid arthritis the occurrence of true ankylosis was not found. His own experience of subcutaneous nodules in rheumatoid arthritis did not enable him to agree with Dr. Hawthorne as to the frequency of their occurrence, but the fact had to be accepted, and it was a connecting link with the so-called true rheumatism. He was strongly disposed to regard the occurrence of nodules even without a history of rheumatic or gouty antecedents as indicative of the so-called arthritic habit of body. In those instances of sequelæ in the joints arising out of cases of acute infective rheumatism the primary disorder failed to pass away and a lingering arthritis remained. In those cases the disorder had alighted on a strumous soil and the blended diathesis was responsible for the result. Many of those cases were regarded as examples of rheumatoid arthritis and the exact diagnosis was not always easy because infective rheumatism might and did sometimes open the way for later developments of rheumatoid arthritis, and, as they had just seen, the same deforming arthritis might eventuate after attacks of true articular gout with no specific rheumatic antecedents. It was difficult to deny the possibility of a blended condition of true infective rheumatism and true gout. The study of rheumatoid arthritis in its clinical features and its morbid anatomy indicated a marked variety of conditions. The specificity or unity of rheumatoid arthritis was held by some observers to be open to grave doubt. Dr. Derwent Parker had declared that all examples of the disease were solely the outcome either of true rheumatism or of true gout. He entertained no doubt that gouty arthritis was capable of inducing most of the changes that were to be witnessed in a well-marked example of rheumatoid arthritis, but the two conditions were not identical: the process leading up to the one was very different from that inducing the other. It was not a common event for true rheumatism to lead to the specific disorder recognised as rheumatoid arthritis, and thus his experience refuted the dogmatic feeling of Dr. Derwent Parker on those points. Some evidence had been afforded by Dr. Bannatyne in support of the contention of the dependence of rheumatoid arthritis proper on a toxæmic invasion and had already led to measures of treatment conceived to be appropriate. He did not think that up to the present time a case had been made out for a constant and specific toxic element, bacillary or otherwise, in the pathogeny of all cases of rheumatoid arthritis, and such specific element, if such there were, was therefore yet to be sought. They had to take note of neuro-arthritic conditions in relation to the pathogeny of rheumatoid arthritis and the occasional association therewith of cardiac disorders. In respect of the term "rheumatoid arthritis" it was unjustifiable to state definitely that there was any unity of pathogeny or to cite any uniform or definite cause when considering all examples of the disease.

EDINBURGH OBSTETRICAL SOCIETY.

Deciduoma Malignum.—Varix.

A MEETING of this society was held on March 13th, Dr. R. MILNE MURRAY, the President, being in the chair.

Dr. ALEXANDER BRUCE and Dr. ELSIE INGLIS communicated a paper on a case of Hydatid Mole with death six months afterwards from Cerebral Hæmorrhage due to Deciduoma Malignum. The patient was at first under the care of Dr. Elsie Inglis, who in January, 1899, removed a hydatid mole; the patient made a good recovery. The menses returned and were normal and the patient appeared to be in good health. Six months afterwards, in June, she showed symptoms of cerebral hæmorrhage and was removed to Dr. Bruce's ward in the infirmary. She died three days after admission. At the post-mortem examination a hæmorrhage was found in the left occipital lobe, small hæmorrhagic nodules were scattered throughout the lungs, and in the uterus two similar nodules were embedded in the muscular tissue. Microscopical sections of all these structures were made and all showed the structure of so-called deciduoma malignum—viz., masses of protoplasm with numerous nuclei and groups of small epithelial-looking cells containing a single nucleus, which in the uterine sections were in connexion with the villi. This was the fourth reported case in which metastasis had occurred in the brain, and it was also interesting because there were no local uterine symptoms, the patient appearing to be in good health until the cerebral hæmorrhage occurred. The paper was illustrated by micro-photographs of sections thrown on the screen by a projection apparatus.

Dr. R. C. BUIST (Dundee) gave notes of a similar case. The patient had suffered from an almost continuous metrorrhagia following a miscarriage at the third month. The uterus was curetted and the anterior wall was found to be thickened; the cavity was quite smooth. The bleeding returned in three weeks and a tumour rapidly formed in

the right iliac region. Three months afterwards the tumour was of the size of a child's head, and was removed by abdominal section together with the uterus which was found to have increased considerably in size. Three weeks after this operation, lung symptoms supervened, with rapid breathing and pain, and friction could be heard on deep inspiration. The patient died from exhaustion about five months after the first operation. At the necropsy many organs were found to be affected, including the lungs, heart, liver, pancreas, and the supra-renal body. The specimens all showed hæmorrhagic nodules. Dr. Buist showed these and also microscopical specimens on the screen; their special feature was an entire absence of multinucleated protoplasmic masses. He considered that these cases of deciduoma malignum were not all of one type.—Dr. F. W. N. HAULTAIN said that Dr. Bruce's case very fully coincided with one which he had himself examined and treated successfully two and a half years ago by vaginal hysterectomy. Lantern slides were shown of the microscopical characters of Dr. Haultain's case, which demonstrated the two varieties of cellular elements (namely, individual cells with a clear cell-substance), the nuclei of which showed reticulation of the chromatin and large multi-nucleated protoplasmic masses, the protoplasm of which was granular in character with the nuclei deeply stained. Commenting on the pathology and histogenesis of these growths he stated that there were three theories: (1) that it was a sarcoma independent of pregnancy but modified by that condition, this being the view almost unanimously upheld in a recent discussion on the subject at the Obstetrical Society of London; (2) that it was a malignant change occurring in the decidual cells and was thus a maternal sarcoma entirely due to pregnancy, this being the original theory propounded by Sänger from which the term "deciduoma malignum" emanated; and (3) that it was the result of active proliferation of the epithelial covering of the chorionic villi, and hence was of the nature of an epithelioma—to this theory the great majority of recent German observers adhered, and Dr. Haultain strongly supported it. The disease was a rare one, occurring only once in about 2000 pregnancies, and yet fully 50 per cent. of all cases of deciduoma followed the expulsion of a hydatid mole. The upholders of the simple sarcoma theory based their views chiefly on the following points: that in some cases no distinct history of previous pregnancy was present, also that the cells tended to travel by the blood-vessels, and that similar structures had been noticed in sarcoma of the testicle. These arguments might be met by the fact that no case had yet been described outside the child-bearing period of life, and though pregnancy could not be proved, yet neither could the reverse be proved. Everything tended to point to an epithelial character, and the term "deciduoma" might be replaced by "chorio-epithelioma," the term "synclytioma" being too exclusive. The evidence of metastases in the lung which were evidently inactive had already been demonstrated by von Franque and others. Metastases had also been noticed in other structures, where after the removal of the original uterine growth a complete cure had resulted.—Dr. D. BERRY HART also made some remarks.—Dr. BRUCE in his reply stated that it was perfectly clear that these tumours were not sarcomatous; they were derived from an epithelial layer, and the term "chorio-epithelioma" was the more accurate designation.

Dr. S. MACVIE gave short notes of a case of Spontaneous Rupture of a Varicose Vein of the Lower Extremity at the seventh month of pregnancy, with expulsion of a dead fœtus 28 days afterwards.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Doses of Arsenical Preparations.

A MEETING of this section was held on March 8th, Dr. WALTER SMITH being in the chair.

Dr. NINIAN FALKINER read a paper on the Doses of the Arsenium Compounds of the British Pharmacopœia. He said that Dr. R. W. MacKenna, clinical assistant to the Liverpool Skin Hospital, had suggested to him the investigation of the ratio of the doses of the official compounds of arsenium to the percentage amount of arsenium in each compound. The following table summarises his results.

—	Col. 1.	Col. 2.	Col. 3.	Col. 4.	Col. 5.
—	—	—	—	—	1·6 minims Fowler's solution.
As_4O_6... ...	75·77	4·5	0·016	0·016	1·6 ,, De Valangin's ,,
Na_2HAsO_4..	40·03	2·4	0·025	0·030	3·0 ,, Pearson's ,,
$Fe_3(AsO_4)_2 4H_2O$	28·96	1·6	0·062	0·045	—
AsI_3	16·5	1·0	0·052	0·072	7·2 ,, Donovan's ,,

Col. 1.—The percentage of arsenium in each compound.
Col. 2.—The approximate strength in arsenium of equal weights of (*a*) As_4O_6, (*b*) $Na_2H\ AsO_4$, (*c*) $Fe_3(AsO_4)_2 4H_2O$, (*d*) AsI_3.
Col. 3.—The minimum dose of each compound as given in British Pharmacopœia expressed in decimal parts of a grain.
Col. 4.—The minimum dose that should be given of each compound, calculated from the minimum dose of As_4O_6 (as laid down in the British Pharmacopœia of 1898), on the basis of the percentage of As that the compound contains.
Col. 5.—The number of minims of the official liquors that contain each a minimum dose of the compound as calculated in Col. 4.

Two points arose, however, in the consideration of the dosology of the arsenium compounds: (1) the question of solubility and (2) the relation between the chemical constitution of a compound and its pharmacological activity. The first point might arise with reference to the dose of $Fe_3(AsO_4)_2 4H_2O$, but the second point did not appear to have influenced the calculation of the dose of $Na_2H\ AsO_4$, as its dose was less than it ought to be if calculated on its percentage of arsenium; while, according to the view that unsaturated compounds were more physiologically active than saturated, the arsenious compounds should be more active than the arsenic. The table brought out the fact strikingly that weight for weight As_4O_6 was about four and a half times as strong as AsI_3 in the quantity of arsenium that it contained, which might account for the tolerance which had been observed by Mr. MacKenna and other practitioners in the use of Donovan's solution.

Dr. WALTER SMITH observed that there was a great gap in the case of arsenic between its reputed medicinal uses and its known physiological action, as was also the case with respect to mercury. Amongst skin diseases remarkably influenced by arsenic (and he admitted that its use was empirical) he would put at the head of the list pemphigus; then that most distressing complaint, lichen planus; and in the third and last place he would put psoriasis. He directed attention to the curious contrast that there was in their knowledge of the physiological action of inorganic bodies as a group as compared with organic. With regard to chronic arsenical poisoning, he had often given one-thirtieth of a grain of white arsenic per diem, which came to two grains per month, or from 20 to 30 grains in a year, yet he had never produced chronic poisoning after using it for months. Dr. Falkiner had under-estimated the amount when he mentioned one quarter of a grain per gallon as found in beer in England, for up to one grain per gallon had been found.

Sir GEORGE DUFFEY said that Dr. Falkiner's calculation was based solely on the element arsenium, but it was recognised, he thought, by most pharmacologists that arsenious acid and its salts were much more poisonous than arsenic acid and its salts. The element, arsenium, was not to be taken so much into account as the nature of the salt employed.

Dr. CRAIG referred to a case of pernicious anæmia, which he reported some years ago, which was treated by 15-minim doses of Fowler's solution thrice daily. The patient presented himself a couple of months ago suffering from bronchitis, and he had taken large quantities of arsenic during all that time, having got the prescription made up regularly by a druggist.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on March 15th, Dr. Patrick Manson, the President, being in the chair.—The secretary read a paper on Enteric Fever Mortality in Copenhagen contributed by Dr. Schierbeck, Professor in the Danish University. The writer stated that the records of mortality were available for the purpose so far back as the year 1829, and he gave the

number of deaths presumably from enteric fever for each year down to 1899 numerically and graphically, which showed a steady and progressive decline, beginning about the year 1840. If the oscillations were "smoothed" by the usual process the progressive character of the decline became very evident, proving that some factor had been at work since 1841, but how long previously it was impossible to say, the records for the 10 years preceding being less trustworthy. What this factor, or probably these factors, might be could not be determined. For the last 40 years the enteric fever mortality in Copenhagen had compared favourably with those of most European cities. The first public water-supply was opened in 1860 and the sewerage works were commenced at the same time, when the ordinary method of comparing the mean death-rate of the 20 years preceding—viz., 94 per 100,000—with that of the 20 years following—viz., 41 per 100,000—would appear to show a great reduction; but it must be noted that these events occurred at a time when the mortality was already falling. He would not say that the water-supply and sewerage had no influence, but that it was not so evident as appeared at first sight.—Dr. Christopher Childs then read a paper by Dr. J. T. R. Davison on Soil and Typhoid Fever in which he aimed at showing that the conversion of Buenos Ayres from one of the most unhealthy cities in the world in 1872 to one of the healthiest at the present time was owing not directly to the introduction of a pure water-supply and an excellent system of sewerage, but to the effects produced by these improvements on the condition of the soil. At the former date the soil was riddled with cesspits, the population drank water from shallow wells, rainwater stored in underground tanks, or water taken from the river, and the place was subject to frequent inundations. Now seven-tenths of the population were provided with pure water and their houses were connected with the sewers, though the growth of the city was so rapid that it could not be overtaken by these works, and of the 788,211 inhabitants, 559,830 were within and 228,381 were without the area covered by these sanitary improvements. During the few years between 1872, when registration first became trustworthy, and the commencement of the works the enteric fever mortality had been 0·6 per 1000 and it was latterly but 0·3, yet a comparison year by year of the successive extensions of the water-supply and connexions with the sewers with the varying mortality from typhoid fever did not show any direct relation. He believed that the typhoid bacillus, being aerobic, throve in polluted pervious soils, but could not live in impervious clays, such as those on which the city was built, or in the concentrated sewage in cesspits, and that though it was often water-borne it oftener rose with the movements of the air from the surface soil during variations of atmospheric pressure and the warmth of houses at night. He considered that the chief cause of the reduced mortality was the energetic action of the authorities in the cleaning, ventilation, and general improvement of the huge lodging-houses or tenements known as "conventillos," the prevention of overcrowding, and above all the paving and cleansing of the "patios" or courts around which they were built and which formerly presented an almost incredible surface pollution, together with the abolition of cesspits.—Dr. H. F. Parsons criticised both papers, commenting on the ambiguity of the term "typhus" as used by continental writers.—Mr. Shirley Murphy did not consider Dr. Schierbeck's argument as to the water conclusive, as he had not stated when and to what extent the new supply came into operation. As to Buenos Ayres the effect of the sanitary improvements was not to be expected at once, for the purification of a soil saturated with filth would necessarily be a work of time, and the great improvement in the health of the city after the lapse of 10 years was rightly ascribed to the measures which Dr. Davison considered inoperative.—Dr. Willoughby said that prior to 1860 the population of Copenhagen drew their water from shallow city wells, but in that year a public supply was opened, partly from wells and partly from the Damhus Lake. Since 1890 the supply had been derived wholly from deep chalk wells, occasionally supplemented to some extent from the Sönder Lake. He could not say more on the sewerage than that the sewers begun in 1860 received waste waters and rain only, for as late as 1891 there were very few water-closets. He thought that the apparent reduction in the mortality subsequently to 1845 was probably explicable by the diagnosis of enteric from other fevers, but that the reductions after 1860 and again after 1887 were the results of the substitution first of a fair, and next of an excellent, water-supply for the polluted wells. As to Buenos Ayres, he entirely agreed with the views expressed by Mr. Shirley Murphy.—Dr. Childs indicated a number of points on which further information and explanation were necessary before Dr. Davison's arguments could be even seriously considered and he was quite unable to accept his assumptions with regard to the life-history of pathogenic microbes.—Dr. Newsholme and Major Macpherson, R.A.M.C., also took part in the discussion.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on March 19th, Mr. F. A. Southam, the President, being in the chair.—Mr. E. Stanmore Bishop introduced a discussion on Post-partum Hæmorrhage and its Treatment. He drew attention to the present teaching as laid down in the leading text-books on this subject and sketched shortly a case of the kind treated according to accepted ideas and its probable result. Mr. Bishop discussed the theory of causation and showed that all causes were divisible into two categories. He strongly advocated external abdominal aortic compression and gave reasons for the choice of this method.—Dr. E. Vipont Brown said that the description of post-partum hæmorrhage given by Mr. Stanmore Bishop was not imaginative, as Dr. Fothergill had suggested, but a terribly realistic picture of an experience with which many general practitioners were only too familiar. The reason why Dr. Lea and Dr. Fothergill thought these cases so extremely rare was doubtless that there was never time to send for the consultant. Long before the services of a consultant could be obtained the crisis was over for better or for worse. It was known that when physically tired and worn out a strong psychical stimulant would sometimes enable a person to do a great deal more work without apparent fatigue, showing that the exhaustion was nervous rather than muscular. And so he thought the "whipping" (as Mr. Bishop called it) to which the womb was subjected in what had hitherto been the ordinary treatment in cases of post-partum hæmorrhage might act as a strong nerve stimulant and was not always so useless as Mr. Bishop's paper might lead them to suppose. Indeed, it was known from experience that it did sometimes prove effective. His own practice had hitherto always been in severe cases to insert one hand into the womb and to knead with the other hand on the abdominal wall. Imitation, however, was the sincerest form of flattery, and the next time he had to deal with a severe case of this kind he would undoubtedly place the foot of the bed upon the dressing-table and compress the abdominal aorta.—Dr. Leslie Jones said that he had never seen a fatal case of post-partum hæmorrhage. In the fatal case described by Mr. Bishop he thought almost everything that was wrong had been done, and what was right had been done at the wrong time. The uterus was not accustomed to, and did not understand, rough treatment by pounding and squeezing from outside; what it did understand, and would readily respond to, was a stimulus applied to its inside similar to that recently supplied by the fœtus in the expulsion of which its efforts had just been engaged—efforts which it was quite able and willing to resume if suitably reminded and encouraged. He strongly advocated the method which he had for nearly 30 years adopted. The method was this: a full dose of opium having been given—nowadays morphia: subcutaneously—the left hand was introduced into the uterus and the fist closed; then the right hand from without seized the closed fist in the womb, and in doing so must necessarily take in its grasp the uterine wall in its full extent behind as well as above and in front, and this no matter how relaxed and eluding the uterus might be; then the right hand pressed the closed fist and with it the uterus downwards into the pelvis, when hæmorrhage, if there still was any, immediately ceased. The uterus would soon begin to contract and would endeavour to expel the fist which, far from being withdrawn, was slightly pressed upwards against the force applied by the right hand and was only removed when it had been compulsorily expelled. Then was the time for ergot and such external stimulating agencies as ice—cold applied to the cervix or fundus—but the chief thing was to keep the uterus, now firmly contracted, grasped in both hands, and pressed into the pelvic cavity. At the same time that this was being done someone near should raise the pelvis on three or four pillows, and in cases where the hæmorrhage had been extreme and exhaustion alarming a large quantity of salted water should be injected into the bowel. Then,

too, strychnine was most valuable. Compression of the aorta as a means of controlling hæmorrhage was very old and had been deservedly abandoned. Under the circumstances in which it might be considered desirable it was useless and entailed loss of precious time when every moment was of importance. The danger, too, of compressing the vena cava should not be so lightly set aside. If the aorta were effectually compressed under the conditions which must necessarily obtain it would be next to impossible to avoid compressing the cava at the same time. It was superfluous to dwell on the danger of doing so. He had no experience of, and never had necessity to resort to, any of the numerous methods described by Mr. Bishop and which had been adopted in the case that had been depicted, and he referred to a well-nigh fatal case of post-partum hæmorrhage where, had he dallied with attempts to compress an empty aorta, the uterus would never have awakened from the refreshing sleep Mr. Bishop so strongly pleaded for it, nor would the patient. While admiring the ingenuity of Mr. Bishop's theorems and acknowledging the soundness of some of his propositions he had heard nothing that would induce him to abandon a method which through a long series of years had never failed him.—The following gentlemen also took part in the discussion: Dr. A. W. W. Lea, Dr. W E. Fothergill, Mr. R. D. Cran, Mr. S. Bagley, Dr. G. A. Junk, and Mr. J. E. Harburn.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—A meeting of this society was held on March 14th, Mr. Rutherford Morison, the President, being in the chair.—Dr. H. P. Bennett exhibited in the dark room a case of Concussion Injury of the Eye (a hole in the macula) and expressed the opinion that the hole had been produced by contre-coup.—Dr. J Limont brought forward a case of Generalised Lichen Planus. The patient was a woman, aged 52 years, showing lichen patches upon the forearms and legs and discrete papules over the back and body surface generally, especially over pressure sites, such as waistbands and garters. The duration of the condition had been two months.—Dr. Limont also showed a case of Erythema, the patient being a woman, aged 38 years, who had suffered from various degrees of erythema for 18 months. Her condition began with sore throat, febrile disturbance, and gastro-intestinal symptoms. She now exhibited red patches, papules (the tuberculate form), urticarial weals, in places serous effusion producing vesicles, and in places purpuric patches. He thought the case was due to intestinal disorder and absorption.—Dr. Oliver and the President described a case of Panhysterectomy at the eighth month of pregnancy for Cancer of the Cervix. The patient was 39 years of age and was the mother of nine children. She had suffered from uterine hæmorrhage since the birth of her last child two years previously. For 18 months the hæmorrhage had been increasing in severity. She presented herself pregnant at the eighth month when carcinoma of the cervix was recognised, and the child being viable delivery by the abdomen and total hysterectomy were advocated in preference to the risk of natural labour at full term. Mother and child had both done well and were now shown.—Dr. A. M. Martin brought forward two children the subjects of Unilateral Congenital Dislocation of the Hip. Both labours were normal. The condition had only been recognised when the children commenced to walk. In one patient, aged six years, an open operation by Lorenz's method had been performed. Previous attempts at bloodless reduction had been futile. At the operation the head of the femur was found on the dorsum ilii, the capsule was long, there was no ligamentum teres, there was a good acetabulum, the head of the bone was normal and was easily replaced on strongly abducting and inverting the hip, the wound was sutured, and the limb was kept in the above position with plaster-of-Paris.—Dr. G. R. Murray showed a case of Musical Mitral Systolic Murmur. The patient was a boy who had a strong rheumatic history and exhibited outward displacement of the apex external to which was heard a systolic murmur having a decided musical character. Although heard over the whole præcordium, the point of maximum intensity was as above described and the murmur was therefore considered to be of mitral origin. Dr. Murray remarked upon the rarity of this murmur and stated that musical murmurs were usually aortic in origin and diastolic in time.—Dr. Oliver concurred in this view.—Dr. Beattie, from observation on a long series of musical heart murmurs, expressed his belief that they more frequently resulted from dilatation than from endocarditis, requiring for their production thin membranous cusps but slightly separated, and still capable of trilling upon one another by imperfect contact. They were always regurgitant, never obstructive—more frequently systolic and of tricuspid or mitral origin than diastolic and of aortic origin. By far the most frequent musical murmur was one of tricuspid regurgitation and quite often secondary to mitral stenosis. Their musical character was usually temporary, being abolished by either further dilatation of the orifice or by recovered compensation and restored perfect closure.—Dr. I. G. Modlin brought forward a child, aged nine years, who had been operated upon for Acute Intestinal Obstruction. The child was now perfectly well and on ordinary diet.—Dr. C. H. Bryant brought forward a girl, aged 14 years, who for five months had been the subject of Increasing Double Ptosis which was at first considered to be hysterical; lately, however, external ophthalmoplegia had been added in the distribution of both third nerves and the right sixth nerve, but without any iridoplegia. There were also double facial paresis of both upper and lower divisions. There were no nystagmus, no dysphagia, no vomiting, and no headache; the optic discs were normal.—Dr. R. P. Ranken Lyle read a short paper on Placenta Prævia.—A discussion followed, which was taken part in by Dr. Calthrop, Dr. Murphy, Dr. Stuart, and Dr. Peart.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on March 13th, Dr. Robert Jardine, the President, being in the chair.—The President read notes on two cases of Measles in the Puerperal Woman occurring in the Glasgow Maternity Hospital. The first patient was 30 years of age and a primipara. The puerperium was normal till the seventh day when her temperature rose in the evening to 101° F., and by the eleventh day it was 103° and 104°. Two days later a copious measles rash appeared and the temperature fell to 99°. Until the rash appeared the cause of the febrile disturbance could not be determined, there being no coryza; septic absorption was, however, excluded. The source of infection was traced to the house in which the patient had lodged before admission, the period of incubation being 14 days. She was removed to the Fever Hospital, where she made a good recovery. The after-history of the child was unknown. The other patient was 28 years of age and in her second confinement. The measles rash was first appearing when this patient was admitted to hospital early in the first stage of labour. Her temperature was 99°. Labour lasted nine and a half hours and was normal. Next day the rash of measles was well marked and on the third day the patient was removed to the Fever Hospital and did well. The child was still free from measles two weeks later, although exposed to infection for the first three days. Perhaps the child was rendered immune. He also referred to a case where a child suffering from measles was placed in bed beside a woman who had been delivered on the previous day. The mother escaped although the newly-born infant developed the rash on the eighth day after birth.—Dr. G. Balfour Marshall referred to a case where a newly-born child became feverish on the second day after birth and twenty-four hours later scarlet fever showed itself. The mother nursed the child and remained immune.—The President also read notes on a fatal case of Septicæmia arising from Gonorrhœal Rheumatism. The patient, a woman, aged 31 years, and in the eighth month of her sixth or seventh pregnancy, was suddenly seized with intense pain in her right knee, which was, however, not visibly swollen. The pain continued intense and was only relieved by hypodermic injections of morphia, all local and other remedies failing. Her temperature varied from 99° to 100°. This continued for a week when premature labour set in and was completed under chloroform as movements of the knee-joint were so painful. While under chloroform the knee-joint was punctured by a hypodermic syringe and some sero-pus was withdrawn. Next day the joint was opened and a little pus was withdrawn. This was bacteriologically examined and only staphylococci were found. Gonorrhœal rheumatism was diagnosed and this was confirmed by the infant developing an intense gonorrhœal ophthalmia. On the second day of the puerperium the mother's temperature rose to 104° and her pulse to 140. On the third day she was restless and maniacal. On the fourth day her temperature fell but rose

again, and she died on the sixth day after intense suffering. The right wrist became painful and a septic punctate rash appeared on both wrists on the third day. There was no distension or pain in the abdomen.—Dr. Carstairs Douglas who saw the case was impressed by the virulence of the attack and thought it probably due to a mixed infection. No gonococci were found in the fluid from the knee-joint.—Dr. Jane B. Henderson read an account of a visit to a Hygienic Dairy-farm near Toronto.—Dr. John Edgar read notes on a case of Anus Vulvalis, the opening being just in front of the fourchette of the vulva.—Dr. A. W. Russell described a similar case.—Dr. Russell read notes of a case of Hydrops Amnii with Twins. The uterus contained over 16 pints of liquor amnii.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 14th, Dr. E. Wearne Clarke, the President, being in the chair.—Mr. Richard Favell showed a female patient with a large Pigmented Mole on the left cheek 10 inches in circumference. After an attack of small-pox 13 years ago the mole became scaly and encrusted and now it formed a large, prominent, and unsightly mass occupying nearly the whole of the cheek. Long silky hair was growing from its lower edge.—Mr. Snell introduced a young man from whose vitreous he had removed a piece of steel by the electro-magnet. Two months had elapsed since the accident and at the time of the operation the splinter of steel was surrounded by a mass of effusion.—Mr. E. J. Scorah showed an eye in which a piece of steel was so firmly embedded in the coats of the eye close to the optic disc that it could not be removed by the electro-magnet and enucleation subsequently became necessary.—Mr. H. Clapham showed a fœtus with large Exomphalos.—Dr. Arthur J. Hall showed the following cases: 1. Locomotor Ataxia. 2. Arsenical Alcoholic Neuritis in a young married woman There were marked arsenical pigmentation of the abdomen and incomplete paralysis of the arms and legs. 3. Hydroa Gestationis. 4. Ringworm of the Hand in a child, aged 12 months. There was no infection elsewhere and microscopical examination of the scales showed large spores in chain formation. Infection from animal source was regarded as probable. 5. Severe Gout in a man, aged 35 years, with very large tophi, especially about the hands and elbows. 6. Chronic Rheumatoid Arthritis in a young woman, with considerable deformity.—Dr. Hall also read a paper on the Treatment of Varicose Dermatitis of the Legs. After referring to the pathology of the disease and the necessity of distinguishing it from eczema, he referred to the value of zinc gelatin properly applied in removing the pain and swelling and enabling the patient to get about in comparative comfort. The method adopted was to encase the whole leg up to the knee in a thick coating of zinc gelatin dabbed with cotton-wool to form a feltwork and to renew it every three days. Should an ulcer be present it could be treated with suitable dressings at the same time. The advantages claimed for the zinc gelatin treatment were: (1) cheapness, common gelatin and the cheapest calamine making quite as efficient a material as the more expensive articles and costing only about 8*d*. per pound; (2) facility of application and removal; (3) impossibility of displacement, however much the limb might be used; (4) arrest of pain and irritation often in a few hours, so that the patient could go about on the leg without discomfort; and (5) its value as a protective against any injury or irritant when continued after the inflammation or ulceration had subsided.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held at 20, Hanover-square, W, on March 15th, Dr. Frederic Bagshawe being in the chair.—Mr. Pagan Lowe (Bath), in re-opening the discussion on Anæmia, confined his observations to the two forms of primary anæmia, chlorosis and pernicious anæmia. He considered that they were two distinct diseases which could easily be separated from each other by the aid of the microscope, and that whilst change of air in addition to iron did good in chlorosis, idiopathic anæmia could not be successfully treated without rest in bed, and that the earlier these patients were put to bed and given arsenic the better. He deprecated the daily hot bath for young people and considered that it was one of the causes of chlorosis, whilst Charcot's bath was a principal assistant in his treatment of simple anæmia.—Dr. Haig referred to the intimate relation existing between anæmia and the quantity of uric acid in the blood and urine. He looked upon anæmia as an almost universal disease in eaters of flesh and drinkers of tea. All the drugs that cured anæmia were drugs that cleared the blood and urine of excess of uric acid. He advised a diet free from uric acid as a preventive of all forms of anæmia.—Dr. Arthur Waddell said that the disease was essentially hereditary.—Dr. E. Kingscote discussed the question whether the chlorotic heart was large or small.—Dr. Fortescue Fox said that numerous cases of secondary anæmias were notably benefited at spas or baths of various kinds. He considered that the anæmia of rheumatism was sometimes increased by a course of sulphur waters and must be carefully handled. That of commencing kidney disease was helped by chalybeate springs, especially when taken artificially heated. The anæmia of old age (a part of failing nutrition) was relieved by warm, but not hot, baths. Hot baths were injurious in all forms of anæmia.—Dr. Bezly Thorne said that in the course of a long experience he had never met with a case either of chlorosis or of the more persistent form of anæmia in which a sallow complexion was partly veiled by the high colour produced by degenerate vessels, in which the urine had not been scanty and loaded either with uric acid or urates, while at the same time the motions showed a greater or less deficiency of biliary colouring. He attributed the superlative benefit derived from the Schott-Nauheim methods in anæmia very largely to the free diuresis which that treatment almost invariably rapidly induced.—Dr. E. Solly (Harrogate), Dr. W. Bain (Harrogate), and Dr. StClair Thomson also took part in the discussion.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on March 13th at the Birmingham Medical Institute, the President, Mr. Jordan Lloyd, being in the chair.—Dr. Short showed a case of Motor Aphasia with Retention of Writing Power. The patient was a woman, aged 37 years, who had had right hemiplegia two days after confinement six years ago, probably from blocking of the first and second branches of the middle meningeal artery by a clot. There were signs of old mitral stenosis present. She could say "yes" and "no" in an interjectional manner, but not spontaneously. Considering the loss of power in the right hand still present she could write fairly well, make figures, add up correctly, write from dictation, or copy (either print or manuscript), and could also read well. Although unable to say a single word at command she talked in her sleep and occasionally sang a few lines of songs she had known many years ago.—Dr. Short also showed a case of Amyotrophic Lateral Sclerosis occurring in a man, aged 35 years. The disease was of seven months' duration, and was of the type in which the atrophy was in advance of the spastic symptoms. There was marked wasting of the deltoids and the extensors of the hands and wrists with excessive deep reflexes in both arms and legs. Up to the present there had been no sign of mischief above the cervical enlargement, the speech, deglutition, and mental condition all being normal with absence also of jaw-clonus.—Mr. J. T. J. Morrison showed a specimen of Pyelo-nephrosis with Double Ureter.—Dr. Douglas Stanley read a paper on Alterations of Sensation in Lesions of the Brain.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of the Pathological and Microscopical Section of this society was held on March 21st, Dr. J. Hill Abram being in the chair.—Dr. Smart showed a specimen of Aortic Aneurysm; also Renal Calculi.—Dr. J. Wiglesworth showed a specimen of Cystic Degeneration of the Kidney with a blind ureter in the form of a nipple-like process.—Dr. Peet showed a specimen of Colloid Cancer of the Right Lung from a woman, aged 54 years. It weighed 4 lb. 13 oz. and appeared to have spread from the pleura to the lung. The left lung was free from new growth and weighed 14 oz. The peritoneum was studded with small growths of a similar nature.—Dr. Peet also showed a specimen of Abscess of the Pancreas complicating Bright's Disease from a girl, aged 14 years.—Dr. Peet also showed a specimen of Tuberculous Tumour of the Brain secondary to pulmonary tuberculosis in a child, aged 11 years.—Dr. Frank H. Barendt showed a microscopic section of Lupus Non-exedens removed by operation from the submaxillary region of a child, aged six years.—Dr. Karl Grossmann exhibited sections of a case of Cystic Degeneration of the Retina.—Dr. Alexander exhibited a specimen of an Enlarged Prostate with Chronic Cystitis of the bladder.—Dr. Keith Monsarrat showed a Sub periosteal Sarcoma of the Lower Jaw.—Mr. Hugh E. Jones demonstrated the Surgical

Anatomy of the Temporal Bone by means of sections and dissections of the bone, illustrated by lantern slides. The specimens shown were unique and most valuable as guides in operative surgery.—The demonstration was followed by a discussion in which Mr. F. T. Paul, Mr. C. G Lee, and Dr. W. B. Warrington took part.—Mr. E. R. Bickersteth read the clinical notes on a case of Tetanus with Facial Paralysis.—Dr. Warrington and Dr. Griffith read a note on the Morbid Changes in the Nervous System in the above case and ordinary tetanus.—Dr. Monsarrat read a note on a Congenital Renal Growth.

ÆSCULAPIAN SOCIETY OF LONDON.—A meeting of this society was held on March 22nd, Mr. W. C. Worley, the President, being in the chair.—Mr. W. Campbell M'Donnell showed a child with a very Defective Auricle and an Incomplete Auditory Canal.—Mr. F. Hewitt Oliver showed a specimen of Ruptured Tubo-ovarian Pregnancy of about three months from a multipara, aged 31 years. The patient died eight hours from the onset of violent abdominal pain.—Dr. B. G. Morison read a paper on the Rational Treatment of Dyspepsia. He classified dyspepsia as (1) the atonic, anæmic, or neurotic; (2) the catarrhal and acid forms; (3) that due to organic stomach changes; and (4) related to diseases of other viscera than the stomach. For the treatment, if vomiting was present, a very small quantity of milk-and-water, alternating with beef-jelly, should be given half-hourly by the mouth and a mixture of bismuth and peppermint, while if the vomiting then continued a hypodermic injection of morphine should be administered. He advised rhubarb and belladonna or the compound pill of asafetida when constipation was associated with dyspepsia. Gastric irrigation with permanganate solution or saline solution in gastric dilatation was advised.

SOUTHPORT MEDICAL SOCIETY.—A meeting of this society was held on March 13th, Dr. R. Harris, the President, being in the chair.—Mr. R. J. Hamilton (Liverpool) showed: (1) A case of Subacute Glaucoma with some Unusual Features (there was, however, marked restriction of the field of vision on the inner side); and (2) a case of Gonorrheal Iritis where the patient had suffered very little pain in the eyeball; no simultaneous joint affection was present.—Dr. C. Pinkerton read a note on the Presence of Kreatinin in Urine. In large quantities this substance gave the Fehling test for sugar and might lead to errors in diagnosis.—Dr. H. Smurthwaite read a few remarks on a case of Shock from Electric Current of High Potentiality.—Dr. D. M. Hutton read a paper on Diseases and Injuries due to Insects and described the lesions caused by the presence of the larvæ of diptera (myiasis) both in the alimentary canal and in the skin and mucous membranes.

Reviews and Notices of Books.

Disciples of Æsculapius. By Sir BENJAMIN WARD RICHARDSON, M.D., F.R.S. With a Life of the author by his daughter, Mrs. GEORGE MARTIN. In two volumes. London: Hutchinson and Co. 1900. Price 36*s*.

THESE two large volumes, which comprise 827 pages, contain some excellent writing and some interesting sketches. The first 12 pages are devoted to an outline of the story of Sir Benjamin Ward Richardson's own life, the rest of the volume comprising 25 monographs—Harvey after Death; John Keats; William Gilbert, the First Electrician; Thomas Wakley; Benjamin Rush, the American Sydenham; Vesalius and the Birth of Anatomy; Hermann Boerhaave and the Origin of Scientific Medicine; Antony van Leeuwenhoek and the Origin of Histology; William Cheselden; Antonio Scarpa and Surgical Anatomy; Richard Wiseman and the Surgery of the Commonwealth; Ambrose Paré and the Birth of French Surgery; John Mayow; John Arbuthnott; John Snow; John Brown and the Brunonian System; Richard Mead; John Baptist Morgagni and the Birth of Pathology; René Laennec; William Hunter; Joseph Priestley and the Discovery of Oxygen; John Friend, the Medical Historian; Edward Jenner; and Sir Francis Bacon as a Master of Physic. The chapter on Harvey after Death tells us of his first burial in the vault of the Harvey Chapel at Hempstead, where the remains rested some 226 years, until that day when eight Fellows of the Royal College of Physicians of London carried the leaden case containing the remains out of the vault and placed it in a sarcophagus of Sicilian marble in the Harvey Chapel—the works of Harvey and a scroll with other records being laid upon the leaden case by the hands of Sir William Jenner. In writing of Keats Sir Benjamin Ward Richardson enjoyed the advantage of having among his friends Henry Stephens, who had shared rooms with John Keats in their student days. He is thus speaking with some authority when he writes: "It has been said that Keats, although educated for our own profession of medicine, had no talent for it. In that vulgar acceptance of the term, which converts talent into success as tested by the money-getting standard, the height and splendour of the idol of the market-place, that may be true. It requires an immense amount of inborn stupidity, and withering of heart, and lowering of soul, and worship of dumb ugliness to secure success in the money market of a profession which in its purity is too exalted for wealth either to nourish or debase. But if Keats had once tasted the true spirit of medicine he would, I believe, have become one of her greatest sons—an addition, perchance, to the some eight or ten of the men of all time whom medicine claims as her own."

The memoir of Dr. William Gilbert, author of "De Magnete," which was published in 1600 and which may be called the basis of all electrical science, shows Sir Benjamin Ward Richardson as a discriminating antiquarian, for Gilbert's claims have been very generally neglected until quite recently. The bibliographical sketch of Thomas Wakley is the sympathetic appreciation of a personal friend. The picture of Ambrose Paré, Councillor of State and surgeon-in-chief to Henry III. of France, draws a personality full of fascination; as is also that of the neglected genius, Dr. John Mayow, who in the latter half of the seventeenth century discovered the real function of the lungs and foreshadowed the discovery of oxygen in his "nitro-aerial spirit" which he described as "carried round the body with the blood to keep up the animal fire." John Arbuthnott, the "medical scholar," of whom Pope wrote in 1734: "You are fitter to live or to die than any man I know," forms another interesting subject. The friend of Chesterfield, the centre of a coterie which included Garth, Friend, Swift, and Pope, is described by Sir Benjamin Ward Richardson as a "man who during a long life spent in the exhibition of mental traits as varied as they were powerful, while tossing in the whirlpool of political debate, while classic-serving, antiquarianising, science-seeking, satire-writing, wit-making, and fun-distributing, managed, by hook or by crook, to write prescriptions, the physic of which the people and even royalty swallowed, with all good breeding, and with infinitely more faith in its efficacy than ever satisfied the conscience of the renowned prescriber."

Passing by the lives of Mead, Queen Anne's great physician; of Snow, so well known in connexion with work upon chloroform; and of Brown, the author of the Brunonian theory, we come to the stories of the lives of the brothers William and John Hunter. The biographer certainly has done good service by bringing into prominence the work of the elder of these wonderful brethren. He concludes his monograph on the elder with these words: "The brothers Hunter were twins in science, and William was the first-born." Sir B. W. Richardson shows to us the real John Hunter in his work-a-day form, the superior general practitioner of our art, who, not disdaining midwifery,

brought the poet Byron into the world; Hunter, the man of poor preliminary education, but endowed with an extraordinary fertility of mind and power of observation, the patient investigator who flames in the physiological and natural history departments of knowledge as an inextinguishable light. Some 20 pages are devoted to the life of Joseph Priestley, the discoverer of oxygen—a discovery which as we have previously noted had been anticipated by John Mayow—to a description of the unhappy days when the question about the Test Act was being agitated in and out of Parliament in the last decade of the eighteenth century, and to the persecution to which this gentle man of genius continued to be subjected. The article on Dr. John Friend, the medical historian who was committed to the Tower in 1722–23 as physician to the Bishop of Rochester at the time when the so-called Atterbury plot was submitted to scrutiny, is an able one. Friend was not a great and original genius, but in him the world had a good example of the medical scholar of the historical school of thought. Dr. Edward Jenner is described as "a fortunate Æsculapian," inasmuch as he won admiration as a universal benefactor of mankind during his lifetime. The last biography in the first volume is of Francis Bacon, Viscount St. Albans, in all of whose studies physic played a part, who was by nature a physician, and whose death was hastened by the performance of a physiological experiment which exposed him to danger. Bacon's views as to the future of physic are summed up in "The New Atlantis," and Sir Benjamin Ward Richardson gives an interesting sketch of the great Chancellor and wise philosopher, classifying his labours in medical science and art under the headings, "preventive and curative."

The second volume contains 20 memoirs, including that of John Hunter, of which mention has already been made, viz.:—Alexander Munro, professor of anatomy, and the Origin of the Edinburgh Medical School; William Cullen, physiologist, chemist, practitioner, and scholar, and the Growth of Physical Medicine; Joseph Black and the School of Chemical Medicine; Benjamin Bell and Systematic Surgery; John Hunter, William Hewson, Matthew Baillie, John Moore and Mooriana, Thomas Willis, Sir Kenelme Digby; Sir Thomas Browne and the Religio Medici; Thomas Sydenham and Hippocratic Physic; Erasmus Darwin, John Locke, Robert Boyle, Marcellus Malpighi, John Howard, William Alexander Greenhill, John Abernethy and Thomas Young. Two portraits accompany the memoir of Cullen, one showing him in middle life and the second in old age, with shoulders high, face lengthened, and lower lip partly paralysed and fallen. He will specially be remembered as the President of the Royal College of Physicians of Edinburgh who published a memorial on the custom of conferring the University degrees in medicine on persons who had not received a proper medical education. This volume contains biographies of three men who, though not regular members of the medical profession, yet did more than dabble in things medical—Sir Kenelme Digby, the Honourable Robert Boyle, and John Howard. All the three monographs are pleasant reading. Sir Kenelme Digby was a mystic, but made some additions to philosophical medicine which possess influence even to the present day. The work that has made him best known to the medical world is his "Discovery upon the Cure by Sympathy." Robert Boyle was so fond of medical art and, indeed, of medical research that he may fairly be reckoned as a medical philosopher. He published in the Proceedings of the Royal Society the first clinical observations of chylous blood ever recorded and a clear account of the early practice of transfusion, and wrote freely about physic without incurring the wrath of the Royal College of Physicians of London. The work of John Howard in the prisons of Europe in connexion with the construction of hospitals and the causation of gaol fever is told excellently. Concerning this great philanthropist Sir Benjamin Ward Richardson writes: "I listen back to the most eloquent of voices of his own time, to words such as none but Edmund Burke could utter." It is well that the echo of these words should sound their note afresh in the hearts of men of our time. Of the author of the "Religio Medici," the "physician of religion," whose work is so well known to us through the splendid edition of the late Dr. W. A. Greenhill of Hastings, a full account is given with an analysis of Sir Benjamin Ward Richardson's impressions of Sir Thomas Browne's *magnum opus*. In his epitome of Thomas Sydenham's life the biographer says: "I should not, for my part, call Sydenham the inventor of any new system in medicine. He merely, in the midst of much controversy held the old ground, stood by the father and fathers of physics—a medical puritan in scientific as well as political faith"; while of Erasmus Darwin he writes, he "was the most astounding medical light of the eighteenth century and will probably live longer than any Æsculapian of that century." The pages devoted to the life of Dr. Joseph Black will be read with pleasure by all chemists. In the community of Edinburgh he was much loved, attracting to his lecture-rooms dilettanti as well as serious students. His research work on heat, on the cause of fluidity, on latent heat, evaporation, and chemical attraction still prove a valuable source of reference. A careful review of the life and work of Dr. Matthew Baillie is followed by a life of the father of the hero of Corunna, Dr. John Moore, who, the biographer states, was of most distinguished mark in the professional circles of his day. He is known to modern medicine as the describer of the phenomenon of the "aura" in epilepsy and as the historian of the French revolution. He considered Marat one of the vilest and cruellest medical lunatics medicine ever had in her ranks and described him as a ferocious monster.

An interesting article attributes a high position in medicine to Dr. Thomas Willis of anatomical fame. And undoubtedly his work in the seventeenth century, by giving the most exact account which had then appeared of the nervous system, justifies our regarding him as a founder of a school of scientific medicine—a school the aim of which is to find out the causes of disease, and which looks on pathological conditions as aberrations of physiological conditions. The story of John Abernethy is sketched chiefly from Pettigrew's biography, but Sir Benjamin Ward Richardson was intimate with men who knew Abernethy, while patients who had been under Abernethy's care in early days recounted to him anecdotes in respect of the outspoken surgeon with a good many stories of his eccentricities. The pages devoted to Abernethy's personal characteristics are excellent reading. In the medical firmament Abernethy was not perhaps a star of the first magnitude, he shone chiefly with the reflected glory of John Hunter. His students, however, looked on him with the utmost pride—he was both an industrious and a friendly teacher. For them he founded, at St. Bartholomew's Hospital, the Medical and Philosophical Society which immediately after his death was changed to bear, as long as the school shall last, the name of the founder.

As will be gathered from our running commentary upon these volumes, we have found them thoroughly entertaining reading. Such praise of bygone heroes is stimulating to those who follow and Sir Benjamin Ward Richardson has honoured his predecessors in admirable taste, bringing to the task the eloquence and discrimination of a learned and scholarly man. Many woodcuts add an additional charm to the volumes.

A Treatise on Mental Diseases. By HENRY J. BERKLEY, M D.. Clinical Professor of Psychiatry, the Johns Hopkins University. With Frontispiece, six Plates, and 57 Illustrations in the Text. London: Henry Kimpton. 1901. Royal 8vo. Pp. 601. Price 21*s.* net.

THE present work is based upon lectures delivered by Dr. Berkley at the Johns Hopkins University in 1899, and attempts to embody in a comprehensive form all the principal forms of mental diseases. It is divided into three parts.

Part I. deals with the anatomy and histology of the cerebrum and occupies about 50 pages. The account given is concise, clear, and adequately illustrated. The author's standpoint may be judged by his statement that "in mental affections we have invariably to do with a pathological condition in the brain, either in the cells, in the other component tissues, or in both."

Part II. discusses the general pathology of mental disorders on the basis of a rough division into the so-called functional maladies and organic degenerative maladies. The principal kinds of pathological change affecting cerebral nerve-cells and blood-vessels are briefly touched upon, and then the author deals with the main portion of the work—viz., the clinical section. This occupies the third part and fills four-fifths of the book. The classification of mental diseases adopted is based upon that of Krafft-Ebing, with some modifications rendered necessary by recent work. After general observations on etiology, symptomatology, and treatment, the various types of insanity are considered *seriatim*. Those which are described include melancholia, mania, stupor, chronic secondary insanity, general paralysis, senile insanity, alcoholic and other toxic insanities, insanity from bacterial infection (puerperal and febrile insanities), paranoia and periodic insanities, epileptic insanity, idiocy, imbecility, and the psychoses of childhood. The account of the toxic insanities arising from alcohol, opium, and cocaine may be singled out for commendation as clear and full in description. The author supports the view that general paralysis is nearly always due to syphilis. The remarks on paranoia are full and to the point. Dr. Berkley's work will, we think, fulfil the useful purposes of a compendium for practitioners and students of mental disease. Each chapter concludes with a useful bibliography. We note that no reference is made to dementia præcox, a malady to which much attention has been paid in Europe. The chapter devoted to the insanity of the degenerate suffers inevitably by comparison with French and German treatises which still constitute the high-water mark of science in this direction. There is scarcely need to refer to the author's plea in the preface that the work was written "because of the absence from English medical literature of a comprehensive practical work." Instinctively the names of Spitzka and Kellog in America, and of Clouston, MacPherson, and Bevan Lewis in Great Britain rise in our mind.

Transactions of the American Ophthalmological Society's Thirty-sixth Annual Meeting, Washington, D. C., 1900. Vol. IX. Hartford, Conn., U.S.A.: published by the Society. Pp. 200.

THIS volume contains numerous interesting articles and the records of various rare or exceptional cases that have occurred in the practice of the members of this thriving society which numbers nearly 150 members and includes the names of nearly all the best ophthalmologists in the United States. The meeting was attended by 73 members. Two papers were read on the Operative Treatment of Entropion, one by Dr. Arthur E. Ewing of St. Louis, Mo., and a second by Dr. John E. Weeks of New York City. The details are too complicated to be understood by a brief extract. Dr. Charles Stedman Bull records three cases of Vascular Tumour of the Orbit. In one of these cases electrolysis was frequently applied without much benefit except slight consolidation of the tumour. It was determined to excise it. Ether was administered and Dr. Bull was just about to commence the requisite incisions when the tumour suddenly increased greatly in size, attaining the magnitude of an orange. The condition was so alarming that the operation was deferred. At the expiration of a year another attempt was made and on this occasion with success. It proved to be a case of caverno-angioma. In a second case of pulsating tumour of the orbit the common carotid artery was tied with success. The third case underwent spontaneous cure. Dr. Charles Oliver of Philadelphia, Penn., gives the details of a remarkably successful case in which a retrobulbar sarcoma was removed with preservation of normal vision. Dr. George Harlan of Philadelphia, Penn.; Dr. Robert Sattler of Cincinnati, Ohio; Dr. Arthur Ewing of St. Louis, Mo.; Dr. Greenfield Sluder of St. Louis, Mo.; and Dr. S. D. Risley of Philadelphia, Penn., each read papers in which the parts adjoining the orbits, as the frontal sinus, the nares, and the nasal accessory sinuses, were considered in their relation to ophthalmic symptoms and disease. Dr. G. Sluder supplies several instructive photographs. Dr. Herman Knapp of New York City describes a case of Primary (traumatic) Non-infective Thrombosis of the Cavernous Sinus. The injury was from a blow on the eye with the end of a billiard-cue. The symptoms—œdema of the left lids and conjunctiva, exophthalmos, impairment of function of the third, fourth, fifth, and sixth pairs of nerves, venous engorgement, and œdema of the retina with neuro-retinitis—led Dr. Knapp to diagnose thrombosis of the left cavernous sinus. He forthwith applied to Dr. Frank Hartley, one of the surgeons of the New York Hospital, and inquired whether he was willing to clear out the left cavernous sinus (which was supposed to be obliterated by a new infective thrombus) and to prevent the thrombus from extending to the other cavernous sinus by ligating or compressing with a tampon the circular sinus. Dr. Hartley seemed startled at first, as well he might be, but eventually he undertook to operate. The steps of this formidable operation are given in detail. They seem to have been carefully thought out and skilfully performed. The patient lived for 10 weeks and died from extension of the disease. Dr. Lucien Howe of Buffalo, N.Y., contributes a valuable article on Relative Accommodation and Convergence, and describes and depicts an ingenious instrument, which he has devised for the purpose of determining these points, which he has named an "opto-dynamometer." Other articles of interest are by Dr. C. A. Veasey of Philadelphia, Penn., on a case of Excision of Lacrymal Sac and Gland followed by a form of Neuroparalytic Keratitis, and Dr. Harry Friedenwald of Baltimore, Md., on the Treatment of Dendritic Keratitis. This volume of the Transactions contains a memoir and portrait of Dr. Edward L. Holmes, a distinguished American ophthalmic surgeon.

LIBRARY TABLE.

Perfect Health: How to Get It and How to Keep It; by One Who Has It. By CHARLES C. HASKELL, Norwich, Conn. London: Fowler and Co. 1901. Pp. 209. Price 2*s.* 6*d.*—This book is apparently an elaborate puff of another book—namely, "The True Science of Living," by Dr. Dewey. We noticed two of Dr. Dewey's books in THE LANCET of Feb. 2nd, p. 334. Mr. Haskell tried Dr. Dewey's plan and found himself much better. We are perfectly willing to allow that if a man does not want his breakfast he should not eat it, but that eating no breakfast is the cure for every ill we do not believe. The stories of fasts lasting for 50 days must be taken with a very large grain of salt. The testimonials from all sorts and conditions of men

are wonderful reading, especially that from the "Returned Missionary from Persia," who vomited bile "in a pasty form and a harder crusty form in bits and pieces."

The Prolongation of Life. By R. E. DUDGEON, M.D. London: Chatto and Windus. 1900. Pp. 166 and Index. Price 3*s* 6*d*.—This little book, although written by a medical man, is not a medical work strictly speaking, for it treats of health and not of disease. Its eight chapters deal with the subjects of exercise, clothing, bathing, food, drink, tobacco, eyes, and beards, and Dr. Dudgeon's object is, as his prologue tells us, to give people directions for spending a comfortable old age. In this we think he has succeeded, although his remarks apply only to the healthy. His advice on eating and drinking is excellent on the whole, though we feel inclined to differ from him when he says (p. 101) that it is better to eat alone because thus we shall not be tempted to over-eat. This is true, but, on the other hand, eating alone conduces to eating too fast, and the very loneliness seems in many cases to predispose to dyspepsia. Dr. Dudgeon has an objection to woollen fabrics worn next the skin. We do not think that this objection applies universally. Some persons are more comfortable with woollen underclothing and find it suits them. Such persons should, we think, continue to wear woollen. But taken as a whole the book is worth careful study by those to whom it is addressed.

Traité de Chirurgie d'Urgence. Par FÉLIX LÉJARS, Professeur Agrégé à la Faculté de Médecine de Paris, Chirurgien de l'Hôpital Tenon, Membre de la Société de Chirurgie. (*A Treatise on the Surgery of Emergencies.* By FÉLIX LÉJARS, Professor *agrégé* at the Paris Faculty of Medicine, Surgeon to the Tenon Hospital, and Member of the Society of Surgery.) Second edition, revised and enlarged, with 617 Illustrations, of which 249 are drawn from nature by Dr. E. DALEINE, and 150 Original Photographs. Paris: Masson and Co. 1900. Pp. 912. Price 25 francs.—The surgery of emergencies is in one respect the most important branch of the subject. It is at least that portion of surgery with which those who practise their art should be most familiar, for what has to be done must be done at once and time spent in looking up authorities may, and often will, be time that might have served to save a life lost by this delay. It is therefore very important that students should be always especially examined in their knowledge of this department of surgery and failure to satisfy the examiners in it should be considered as much more serious than lack of knowledge in those branches in which immediate action is of less moment. It is evident that it must be very convenient to those engaged in practice to have in one volume a full account of the surgery of emergencies, and we may say at once that Professor Léjars's work fully comes up to our ideal of what such a book should be. It is obvious that very different opinions might be held as to the subjects which would naturally be included under the head of emergencies, but we think the author has acted wisely in including more than might have been absolutely necessary rather than omitting some operation that could be reasonably expected to be included. The illustrations are very numerous; in fact, it might be urged that some of them are unnecessary—for instance, a reproduction of a photograph representing how an operator should brush his nails when endeavouring to render his hands aseptic. We have, however, nothing but commendation for this work and it will be likely to prove of use to every surgeon who can read French. The book is excellently printed.

JOURNALS AND MAGAZINES.

The *Journal of Hygiene*, Vol. I., No. 1. Edited by GEORGE H. F. NUTTALL, M.D., Ph.D., Lecturer on Bacteriology and Preventive Medicine in the University of Cambridge, in conjunction with JOHN S. HALDANE, M.D. Edin., F.R.S., Lecturer on Physiology in the University of Oxford, and ARTHUR NEWSHOLME, M.D., F.R.C.P. Lond. Published quarterly. Cambridge University Press. London: C. J. Clay. Price 5*s*. net.—"The *Journal of Hygiene* has been founded in order to meet a need which has long been felt for a journal devoted to the publication in the English language of original work in hygiene." In these words the editors introduce their new periodical. The first two articles form part of a series of studies on malaria. Of these, the first deals with the Geographical Distribution of Anopheles in relation to the Former Distribution of Ague in England, a paper contributed by Dr. Nuttall, Dr. L. Cobbett, and Mr. T. Strangeways Pigg. The paper is somewhat fragmentary, and we are by no means convinced that the evidence offered justifies all the conclusions which are arrived at by the writers. The second study deals with the Structure and Biology of Anopheles (Anopheles Maculipennis). This work appears to have been carefully done and the illustrations are well drawn and clear. A little more attention to the literary style might well have been given to the letterpress; for example, on p. 58 larvæ are described as "browsing about" and are inferentially referred to as "animals." The following sentence, which occurs on the same page, is not a happy example of literary diction: "The particles that are swallowed accumulate for a certain time until a mouthful of some size is attained and this then suddenly passes into the œsophagus." Dr. Klein's article on Pathogenic Microbes in Milk is by no means comforting. A paper on Industrial Lead Poisoning, by Dr. T. M. Legge (His Majesty's Medical Inspector of Factories), is clearly written and full of information. In one word, it is excellent. Dr. Haldane contributes two papers, the first on a Rapid Method of Determining Carbonic Acid in Air, in which the author describes a portable apparatus for which he claims the merit that it is always ready for use, that it gives quickly results which are accurate, and that no calculations are involved. An apparatus possessing these merits has long been wanted. Dr Haldane's second paper is on the Red Colouring Matter of Salted Meat. It is pleasant to learn that the distinctive pigment of salt meat is not prejudicial to the internal economy when the food is well cooked and that modern research on this point is thus in accord with popular experience in the matter. One of the remaining papers contained in the volume is full of interest and worthy of careful study; it records observations on the artificial modifications of toxins, with special reference to immunity, and is from the pen of Dr. J. Ritchie. An experiment on the Effect of Inhalation of Ethylene, by Dr. J. Lorrain Smith and Mr. A. Percy Hoskins, shows that the effects produced by ethylene are very slight. The concluding paper is written by Dr. Newsholme and is on the Utility of Isolation Hospitals in Diminishing the Spread of Scarlet Fever—a subject on which it is hardly to be supposed that there is any serious disagreement amongst medical men.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., W. F. R. WELDON, F.R.S., and SYDNEY HICKSON, F.R.S. New series, No. 174. London: J. and A. Churchill. 1901. Vol. XLIV. Part 2, March, 1901. Pp. 150. Price 10*s*.—The first memoir contained in this part is on the Development and Succession of Teeth in Halteria Punctata, by H. Spencer Harrison, B.Sc. Lond., demonstrator and lecturer on biology, University College, Cardiff. The author shows that the first dentition of this lizard consists of about 36 minute teeth which originate immediately below the epidermis, labial to the dental lamina; other teeth appear during the incubation period on the dental lamina which are probably members of a second and third dentition, and instead of displacing the earlier set alternate with them. Successional teeth make their first appearance in the premaxillæ some months

after hatching and there are in all five distinct sets up to the time when the young individual measures 21·2 centimetres. Other teeth are found upon the maxillæ, palate, vomer, and mandible. All the teeth, except those of the first dentition, have an outer coating of enamel which contains prolongations of the dentinal tubules. The mode of attachment of the teeth is hyperacrodont. The memoir is illustrated with three plates. 2 The Anatomy of Pleurotomaria Beyrichii, Hilg., by Martin F. Woodward, demonstrator of zoology, Royal College of Science, London. Mr. Woodward's specimens were obtained from Boshu, Japan. The animal is stated to be a typical example of a zygobranchiate diotocardian, and is a form very closely related to the stock from which the monotocardia originated. There are four accompanying plates. 3. Dolichorhyncus Indicus a New Acraniate, by Mr. Arthur Willey. 4. Heteropleuron Hectori, the New Zealand Lancelet, by W. Blaxham Benham, M.A., F.Z S., professor of biology in the University of Otago, with a plate. 5. On Some Parasites found in Echinus Esculentus, L., by Arthur E. Shipley, M.A., Fellow and tutor of Christ's College, Cambridge, with a plate. One of these is a trematode worm, the syndesmus echinorum, François, the anatomy of which is fully given by Mr Shipley; and another is a nematode named oncholaimus echini, of which, however, few details are given. 6. The Scottish Silurian Scorpion, by Mr. R. I. Pocock, with a plate. This specimen, which belongs to the Kilmarnock Museum, lies on its back, and is thus the complement of the specimen found at Gotland in Sweden, which has been named "palæophonus nuncius." This specimen is named "palæophonus hunteri," differing in some particulars from other known palæophoni. Mr. Pocock thinks this ancient scorpion occupies an intermediate position between limulus and eurypterida. Its skeleton supplies a few more links to the chain of evidence pointing to the descent of the scorpions from marine limuloid ancestors.

In the *Veterinarian* for March there is a most interesting article by Professor Mettam, B.Sc., M.R.C.V.S., on the production of surgical anæsthesia by the injection of cocaine into the lumbar sub-arachnoid space. The article is mainly a summary of what has already appeared in THE LANCET, accompanied by extracts from the *Semaine Médicale* and the details of some 12 experimental observations made by two French veterinary surgeons (M. Cuillé and M. Sendrail) upon animals. In equines five cases were attempted. The subjects did not appear to feel sensation in the hind limbs after the injection, although such severe operations as neurotomy, passing setons, the application of the actual cautery, and even ovariotomy, were performed. In cattle and dogs similar injections were also made, the results being equally satisfactory. The site of injection in the horse is found by drawing an imaginary line between the internal angles of the two ilia and taking the exact centre of this. On account of the closeness of the vertebral laminæ this is the only accessible spot. Provided that strict antiseptic precautions are attended to and care is taken that an overdose of cocaine is not administered, there seems to be a prospect that this method of producing anæsthesia will prove useful to the veterinary practitioner, but the difficulties and dangers in the way are much more numerous in the case of a fractious animal than in human patients. The closeness of the vertebral laminæ and spines is in itself a great obstacle, and with a subject that will not keep still in order that the operator may find the exact spot where he can penetrate the neural canal it can be imagined that less time and trouble would be taken by the present method of casting and chloroforming. It will be interesting to note what further progress is made by veterinarians. Mr. Alexander Meek, B.Sc., continues his studies of the "Growth of the Farm Ungulates," giving a further series of tables and statistics relating to the weights of cattle at certain ages. The clinical side is well represented by case notes from various veterinary practitioners and under the headings of "The Month's Progress" and "Science Notes" are items of general interest.

Scottish Medical and Surgical Journal.—The opening article in the March number is on the Edinburgh Hospital in South Africa and its Work, by Dr. Francis D. Boyd and Dr G. L. Chiene. Of the medical cases the principal disease dealt with was enteric fever, rather over 150 cases of which were admitted. The bowels were, as a rule, constipated; diarrhœa was the exception. Thrombosis was present as a common complication, occurring in 6 per cent. of the cases. It came on late in the disease, showing itself in the earliest case on the twenty-sixth day. Usually the veins of the leg were affected, but in one case thrombosis of the branches of the middle cerebral artery gave rise to paralysis with aphasia. Relapse occurred in 5·3 per cent. of the cases. Only one case of the apyrexial type of the disease was noted, in one of the members of the staff who had been inoculated. He had a rash, gastro-intestinal symptoms, enlarged spleen, and typical stools, but the temperature during the five weeks when he was in hospital only once rose to 99·4° F.; as a rule, it was subnormal. Widal's reaction was carried out in all doubtful cases and in most cases where the diagnosis was certain. Dr. T. D. Luke pleads for the more general use of ether as an anæsthetic in general surgery. Other original articles are contributed by Mr. A. W. Mayo Robson of Leeds and by Dr. Francis Kelly of Aberdeen.

Dublin Journal of Medical Science.—The original articles in the March number are: (1) A Criticism on the Light Treatment of Lupus, by Dr. Edward Stapleton; (2) The Nordrach Treatment of Consumption in Ireland, by Dr. P. S. Hichens; (3) Four Cases of Laparotomy, by Professor R. J. Kinkead; and (4) Clinical Report of the Rotunda Hospital for one year, Nov. 1st, 1899, to Oct. 31st, 1900, by Dr. R. D. Purefoy, Dr. H. C. Lloyd, and Dr. P. Carton.

The Sei-I-Kwai Medical Journal. Edited and published by the Sei-I-Kwai or Society for the Advancement of Medical Science in Japan.—The present number of this journal is dated Tōkyō, Jan. 31st, 1901. It possesses the unusual feature that of its 62 pages 20 are in English and 42 in Japanese. The contents of the English portion are—(1) an essay on the Prevention of Tuberculosis in the Navy, by K. Momose, surgeon, Imperial Japanese Navy, translated by S. Miwa; (2) an obituary (with portrait) of Mr William Anderson, F R.C.S. Eng., late superintendent of the Imperial Naval Hospital and professor in the Naval Medical College of Tōkyō; and (3) an obituary of Baron Itō, a nonagenarian botanist. The contents of the Japanese portion are—(1) a case of Cholecystotomy, by K. Takaki, F.R.C S. Eng; (2) a case of so-called Bernhalt's Disturbance of Sensation, by B. Shinshi; (3) an abstract on the Treatment of Diabetes; (4) a discussion on Empyema; (5) a memoir of Mr. William Anderson; and (6) a paragraph on Serum Treatment and the result of Prophylactic Inoculation for Dysentery. Subjoined to the English obituary of Mr. Anderson is an illustration of the Anderson medal, founded by his old pupils, and awarded annually to a naval surgeon, the successful competitor in an examination in surgical anatomy.

Mercy and Truth.—One of the articles in the March number describes the ceremony of opening the Church Missionary Society Medical Mission in Bermondsey. Between Jan. 9th and Feb. 10th there were 563 attendances at the dispensary and 357 visits were paid. It is announced that the annual meeting of the Medical Mission Auxiliary will be held in St. James's Hall on April 30th.

Analytical Records

FROM

THE LANCET LABORATORY.

"CONCORDIA" WINE (SPANISH).

(P. DE OTADUY AND CO., 20, HIGH HOLBORN, LONDON, W.C.)

THIS is a Spanish white wine, suggesting at the same time the Sauterne and the sherry character. Its alcoholic strength approaches more that of sherry than that of Sauterne. The analysis was as follows: extractives, 1·62 per cent.; mineral matter, 0·26 per cent.; alcohol, by weight 13·15 per cent., by volume 16·24 per cent., equal to proof spirit 28·46 per cent.; volatile acids reckoned as acetic acid, 0·156 per cent.; fixed acids reckoned as tartaric acid, 0·32 per cent.; sugar, 0·10 per cent.; and potassium sulphate, 0·67 gramme per litre. The wine is practically free from sugar. From the somewhat excessive amount of potassium sulphate it contains the grape juice would appear to have been liberally treated with sulphate of lime, the so-called "plastering" process. The wine is dry and possesses good flavour and bouquet. Its freedom from sugar is a feature of some dietetic importance.

THE DUPLEX HOT-AIR SPRAY.

(THE HOT-AIR SPRAY CO., 37, YORK-PLACE, EDINBURGH.)

We cannot remark any particular novelty in regard to this apparatus. It consists of a conical flask inclosing a glass test-tube in which the medicament is placed. The flask is intended to contain hot water so as to facilitate the volatilisation of the medicament, be it solid or liquid. A current of air is forced through the inner tube by a rubber aspirator, glass tubes being provided through a rubber stopper after the manner of a wash-bottle. The air in its passage through the tube, especially as it is jacketed with a hot-water container, carries forward the medicament for the purpose of inhalation. In this way it may be used as a hot-air spray for inhalations and for the local application of volatile remedies.

AUTOMATIC DISINFECTOR.

(FELL'S CHLORINE DISINFECTOR CO., ENDON, STAFFORDSHIRE.)

This apparatus is designed for diffusing automatically a quantity of chloride of lime solution in the cistern for flushing and disinfectant purposes. It consists of a pot provided with perforations and containing the chloride of lime. When placed in the cistern the chloride of lime gradually dissolves and thus the water used for the flush is charged with a definite quantity of a powerful disinfectant. The method is by no means new, and the objectionable smell given off by chloride of lime, although it may be assigned to the production of hypochlorous acid and probably chlorine, which are extremely powerful disinfectants, would not be tolerated by the majority of people. It is unpleasant to meet with a chlorous smell in the dwelling-house.

RUBY FIRES.

(RUBY'S LIMITED, PARK-ROAD, BATTERSEA, LONDON, S.W.)

The Ruby fire consists of a compost of small coal with pitch, which is said to be useful as a source of heat for the sick room and "at the same time to act as a powerful yet pleasant disinfectant." This latter claim we may dismiss at once as ridiculous. We need only point out that the combustion of the fire is attended with the production of considerable smoke, and an efficient flue is very necessary to carry this smoke away. Doubtless the smoke possesses disinfectant properties, but care should be taken to keep it out of the sick room. The fire consists of a cylinder block which readily lights, producing instantly a smoky flame which lasts for some time, and when the flame dies out a mass of glowing fuel is left behind. The "fire" yields little useful heat and it could never take the place of an ordinary coal fire, although it may be used with advantage for quickly making a coal fire radiant.

BATTLE OF THE CLUBS.

ON March 9th a meeting of the William's Pride Lodge of the Rotherham Equalised Druids was held at Eckington, Derbyshire, for the purpose of presenting Bro. Hancock with an accident compensation grant of £120 and the secretary, Bro. Norman, with a writing-desk. Among those present was Mr. W. B. Croskery of Eckington, the medical officer of the lodge. After the presentation to Mr. Hancock had been made Mr. Croskery congratulated him and in the course of his speech remarked that the working classes had become a great power in the land. According to the report of the meeting given in the *Eckington, Woodhouse, and Staveley Express* of March 15th Mr. Croskery went on to say that he belonged to a profession which had suffered largely in contract work by want of combination. They had learnt a lesson from the working classes and they were hoping to benefit by combination. The working classes by their efforts to raise their position by combination had shown their employers that they would obtain better remuneration for their services. The medical men by their efforts at combination hoped that their services would be more largely rewarded in the future. The contract work carried on by medical men was paid at the same rate of remuneration that was paid 50 years ago. Now medical education took twice the time and cost twice the money it did then, unqualified assistants had been done away with, drugs had gone up in price, and different laws had come into force, such as the Employers' Liability Act and the Notification Act. All these things gave more work to medical men. At present a conciliation board was meeting in London, composed of the better-class lodges and medical men, and there was a considerable unanimity of opinion that in the past medical men had not received the treatment which they ought to have received, and it was hoped that in the future the modest demands of medical men would be met in an agreeable manner by the combinations of the working classes and that justice, which was all they asked for, would be given to them.

Mr. Croskery's remarks were frequently applauded and Bro. Gaffney, in moving a vote of thanks to him for attending, said that he was glad to hear that medical men had banded together to raise their profession, not only remuneratively, but scientifically. They, as trade unionists, had no desire to grind down the medical profession.

We are glad to find members of a friendly society of the standing of the Druids expressing such sentiments, and we commend this account to those members of the medical profession who have yet to approve the value of legitimate combination and organisation.

Another meeting of the same order, but in connexion with a different lodge—namely, the Kenny's Pride Lodge—was held on March 11th, this occasion also being to present a member with an accident compensation grant. Dr. J. D. Kenny, the medical officer of the lodge, was in the chair. During the course of the proceedings Mr. Gaffney, referring to medical men and medical aid associations, said that he hoped that medical men would demand only what was fair and just. He thought that there could be no doubt that assistants to medical men, as well as drugs and instruments, cost more than formerly. Members of friendly societies were prepared to pay their medical men what was fair, but medical men must remember that these members were only paying in the same sums as they did 30 or 40 years ago. Mr. Richard Kirk expressed the opinion that the time had come for every member to be asked to pay an increased contribution. He noticed that Dr. Kenny still attended members on the old scale. Dr. Kenny asked permission to refer to the question of fees. He explained that when he took the members of the lodge at 3*s.* 6*d.* each he had the colliery club as well and was therefore in a way paid twice over. But for that, he should have gone in for the increase and stood shoulder-to-shoulder with his professional brethren. We congratulate Mr. Gaffney and Mr. Kirk on their opinions and trust that it will not be long before they are put into practice.

THE LANCET.

LONDON: SATURDAY, MARCH 30, 1901.

The Indian Medical Service.

THE history of India has of late been largely a record, as everybody knows, of various deplorable experiences and sad vicissitudes of one sort and another, constituting the medical rather than the ordinary general history of a country. Plague, pestilence, and famine make up a list of evils from which a nation may well pray to be delivered, and it is through such that India has of recent years been passing. Nor can it be said that the latest news regarding the epidemic of plague in that country is reassuring, although it may be hoped that one of those seasonal fluctuations, which have hitherto marked its progress and may be regarded as part of its natural history, is approaching when a temporary lull in the prevalence and mortality of the epidemic may be expected to appear. On the disastrous effect which this succession of calamities has had upon India and its vast native population there is no need to dwell. During the whole of this trying time the officers of the Indian Medical Service have most loyally and patiently devoted themselves to their work. Unhappily, the occurrence of the troubles in China has now to be added to the list of responsibilities of the Indian Government and to the labours of its medical service. Medical officers, recognising the necessities of the situation in the past, have struggled to do their best and have willingly foregone all leave and continued, or been recalled to, their duties in India in order to aid the Government in successfully coping with the urgent requirements of the position. But it is clear that this state of things cannot be continued indefinitely. There arrives a time when the strain becomes more than can be sustained and the probable risks and sacrifices become too great to be contemplated with any equanimity. It is, to adopt a proverbial metaphor, futile to apply whip and spur to a willing but jaded horse; rather in the present case of the medical service should these be used to urge on the lagging intent of the authorities.

We quite recognise that the Government have had to encounter unusual difficulties and has striven to do their best in the hope that these would prove to be of a purely temporary character, but we confess that we cannot regard the matter in that light. The measure which seems to us to be most urgently needed at the present time and the one which would tend more than anything else to lift the Indian Medical Service out of the difficulties which it is experiencing in regard to leave is an increase of its establishment. This is a real grievance and an increasing one. Not only has all leave been stopped but voluntary retirements have been suspended and all medical officers on furlough have been recalled to India. We feel confident that the Secretary of State for India, when he fully realises the position, will recognise the legitimate nature of the discontent to which this state of affairs must give rise and that he will do his best to remove it. This could, in our opinion, be easily done and without any unreasonable strain on the Government finances of India. An increase of 10 per cent. to the establishment is necessary. We calculate that such an increase would suffice to meet all the demands for special duty in ordinary times without interfering with leave. The service would still have to meet any extraordinary emergencies, but if we may judge from the spirit which it has always exhibited it may confidently be counted upon to do this. Let us explain with a little more detail. The Indian Medical Service consists at the present time of one officer for every permanent appointment which has been sanctioned by the Secretary of State plus 20 per cent. for leave purposes and 5 per cent. for casualties. Any extra appointment not on the sanctioned lists has to be filled from this 25 per cent. reserve, and the more of these extra appointments there are the more, of course, is this reserve encroached upon. The service is not recruited to meet Imperial needs in Africa and China and the consequence of all the recent troubles in those countries has brought about the result which we have already stated. Ever since the Chitral expedition of 1895 the same difficulty in regard to leave has prevailed more or less except in 1898. War, plague, or famine, sometimes all three together, have been present, and the whole of the leave reserve has been absorbed owing to medical officers having to be put on special duty. 105 officers are entitled to be on leave at the same time. But we understand that there are at present some 125 in South Africa and China, 56 on sick leave, and some 16 on plague or other special duty. This makes 92 officers short of the requirements for current work.

The hospital arrangements for the expedition to China have been made on a large scale—on altogether too large a scale in the opinion of many—but no one is likely to err on the side of too economical a provision in the present day, and it may be readily understood that the Secretary of State for India was determined to have no debates in Parliament and commissions of inquiry in connexion with Indian arrangements. Be this as it may, the troubles in China have made great demands at an unfortunate time upon the medical services in India, and when they are over something else will be sure to occur in a country like India to create fresh demands for special duty officers. To get over the difficulty and to prevent its becoming a chronic source of complaint there seems to be no way but by increasing the cadre so as to allow the leave reserve to be utilised for the purpose for which it was intended. There is no doubt room for the introduction of several improvements in the Indian Medical Service. Still, it is an old and good, and on the whole a contented, medical service. Long may it remain so and long may it continue to attract the excellent class of candidates which it has hitherto secured, and we trust that the Secretary of State will see his way to effect this object by sanctioning an adequate increase of its establishment.

The Public Health and the Housing Question.

THE duty of providing suitable dwellings for the poorer members of the community is by no means an easy one to fulfil. One of the chief difficulties in the matter was

admirably summed up by Sir JOHN SIMON when he pointed out that the smallness of the earnings of the poor in the lowest paid branches of industry as compared with the necessary costs of wholesome and decent living. This has always been the main fact which has caused trouble and the possibility of rendering that ratio less unfavourable to the poorer workers either by cheapening the costs of life or by bettering their conditions of employment has in a variety of forms been the essential problem for study.[1] In the City of London itself Sir JOHN SIMON had found a state of things which probably does not exist at the present time in any part of the metropolitan area. "Hovels like pits, low sunken between high houses hemmed in by barriers" which excluded every breath of ventilation were a little over 50 years ago situated in the very heart of the City. By way of improvement Sir JOHN SIMON suggested to the civic authorities two possible solutions: "To remove the well-constructed houses of the City in order that its wretched courts and alleys should participate in the blessings of light and air might seem one method of conquering the difficulty which is before you. But I apprehend the opposite alternative of proceeding to a gradual suppression of all residence in the former class of dwellings may more naturally have your approbation."[2] It was by means of a presentation of the stern facts lighted by gleams of humour that the medical officer of the City of London impressed on the City Commissioners of Sewers the conditions which needed alteration; and by his persistent labour he was ultimately rewarded by bringing about a gradual change for the better, at first in the City and later through the country generally, at the later period of his life when he became medical officer to the Privy Council.

The first improvements in the condition of the dwellings of the working-classes were carried out by philanthropic societies. During the first half of the last century the Society for the Improvement of the Condition of the Labouring Classes, which was under the patronage of QUEEN VICTORIA and of the QUEEN DOWAGER, and of which PRINCE ALBERT was the President, and another society called the Metropolitan Association for Improving the Dwellings of the Industrious Classes (which was under the chairmanship of Sir RALPH HOWARD) did a great deal of useful work. In St. Pancras, in Pentonville, in St Giles's, and in Drury Lane, a number of model lodging-houses were built and conducted under rules made to ensure cleanliness, sobriety, and a general propriety of conduct. The buildings were constructed with a view to ensure proper ventilation, drainage, and general cleanliness, and the establishments thus started were an enormous improvement on anything which had previously existed in London. Of late years still greater advances have been made, but up to the present time those who have most profited by the newly-built dwellings have been rather well-to-do artisans than the very poor—the class called by Mr. CHARLES BOOTH the "casual workers." Unfortunately, these people have, as a rule, been unable to pay the amount necessary to obtain even a small flat in the newly-constructed dwellings. As a class they do not generally gain the practical sympathy of those who have devoted most of their time to the study of the conditions of the poor in London. The class, according to Mr. CHARLES BOOTH, is not one in which men are born to live and die so much as "a deposit" from a class of those who from mental, moral, and physical reasons are incapable of better work. It is doubtless a class for which it is extremely difficult to do anything, but it may be hoped with regard to it that the resources of civilisation will not entirely fail to be of use.

The Milroy Lectures which were delivered before the Royal College of Physicians of London by Dr. J. F. J. SYKES and of which the third and concluding lecture was published in THE LANCET of March 23rd, p. 837, deal with the influence of the dwelling upon health. We commend these lectures to the study of our readers. They contain in addition to some well-known and well-established facts a number of personal observations on the present state of the dwellings of the poorer classes in St. Pancras, many of which are very striking. The fact that overcrowding in barracks has been in the past a great cause of high mortality is now a matter of common knowledge, but it is none the less a notable fact that the investigation made into the high mortality of the Foot Guards over 40 years ago and the results which came of that inquiry were the starting-point for enormous improvements in the ventilation of houses generally and particularly in the ventilation of dormitories. Dr. SYKES gives some interesting statistics with regard to the relative mortality in stable dwellings and in the other houses which are to be found in St. Pancras, the district to which he is medical officer of health. It will be noticed from the statistics which he gives that the death-rate from zymotic and pulmonary diseases is excessively high in stable dwellings, and from the statement which he publishes it seems open to doubt whether these dwellings are at all fit for human habitation. Dr. SYKES, in his third lecture, points out the difficulties which have ensued from the alteration of houses of fair size into dwellings for more than one family. One of the most striking pieces of information is that which relates to the inadequate water-supply in some workmen's flats. It seems that in many of these buildings of four storeys no water is laid on above the ground floor and that all the water which is required has therefore to be carried upstairs by the unfortunate people who live there. "There is a vast number of families," he says, "in London living on the top floors of four-storeyed houses the water-taps, sinks, water-closets, and dust-bins of which are situated at the ground floor or basement or in the yard or area, and these houses are about 40 feet high." This state of things is one which demands immediate alteration.

The Metropolitan Boroughs will have much to do in regard to the improvement of the dwellings of the poor. We have no doubt that they will set about the work without delay and carry it out efficiently. In former days, when the enforcement of sanitary regulations was in the hands of the vestries, these bodies too often neglected their duties. The first report of the Royal Commission on the Housing of the Working-classes pointed out that the remedy which legislation had provided for sanitary evils had been imperfectly

[1] English Sanitary Institutions Reviewed in their Course of Development, and in some of their Political and Social Relations, by Sir John Simon, K.C.B. Cassell and Co., London. 1890.

[2] Report of the Sanitary Condition of the City of London for the year 1848-9. London, Brewster and West.

applied in the metropolis, and the Commissioners went on to state that the failure had been not infrequently due to the negligence of the local authorities. Evidence was given to the Commission that insanitary property in many cases was owned by members of the vestries and of the district boards, and from these facts it was obvious that many of the persons whose duty it was to see that a better state of things should exist were those who were pecuniarily interested in keeping them as they were. We have no doubt that members of Metropolitan Boroughs will be guiltless of any such frightful jobbery. The work before them is a very great one, and will need energy as well as honesty to carry it through successfully. By way of making a beginning each Borough Council would be well advised to have a full report made by some efficient officer as to the state of the dwellings throughout its whole area. Efficient sanitation can only be maintained by constant effort, and it is a matter of extreme importance that the Boroughs should not be content to wait with a view simply to clear away the houses of the poorer people, but that all that constant care can do should be begun without delay and should be carried out without intermission. Let us mention only two examples: the present regulations in regard to dustbins are not properly enforced even in the richest parts of London, and it is obvious from Dr. SYKES'S report that there are many dwellings which are at present without a constant water-supply.

The Medical Staff and the Management of the National Hospital for the Paralysed and Epileptic.

THE proceedings at the meeting of governors of the National Hospital for the Paralysed and Epileptic, which took place at the hospital on Saturday, March 23rd, will be found fully reported on p. 981 of the present issue of THE LANCET. The result of the meeting is extremely significant. Our readers know the position of affairs, which was set out at length, not for the first time, in THE LANCET of March 16th, p. 798. The medical staff had on various occasions during the last 10 years requested representation on the Board of Management. The Board had persistently refused the request and at their suggestion different methods had been tried as substitutes for that proposed by the staff. These methods had proved unsatisfactory in actual practice. One of them had been discontinued by the Board without any reason; another had been repudiated by the staff because the Board had not adhered to the conditions on which alone the staff had consented to give it a trial. Finally, in June of last year the staff, receiving no satisfaction from the Board, appealed to the governors, and in their appeal furnished illustrations of faults in the administration of the hospital which the complete absence of medical knowledge in the Board had entailed.

The various efforts of the Board to escape from the position in which the statements of the staff to the governors had placed them may be fairly summarised as follows:—(1) the appointment by the Board of a sub-committee of its own body, which inquired into the allegations and faintly approved the existing methods of administration; (2) the calling of a packed meeting in the "silly season" to secure a vote of the governors approving of exclusion of the medical staff from the administration of the charity; (3) the appointment of Sir FORD NORTH to hold a limited inquiry under circumstances which precluded the staff from having anything to do with the inquiry; and (4) the efforts of certain friends of the Board and of the staff to bring about peace, which were rendered futile by the discovery of the Board that the medical staff intended to maintain their position. There is inherent evidence to show that during the long time in which the Board were presumed to be considering the resolutions of the staff to insist upon proper representation they were organising a decisive move against the staff. For negotiations with the staff were suddenly broken off and simultaneously, through the secretary-director, behind whose name they have persistently hidden their identity, the Board issued a statement in the *Times* and summoned a meeting of governors. This is the meeting which was held on March 23rd, at noon. The motions to be proposed were two in number. The first provided for an inquiry into the allegations by the medical staff of mismanagement in the administration, and the second defined the character and scope of that inquiry. As the first was the only one which came before the meeting we need refer only to it. It stated—

"That inasmuch as the demand of the medical staff for direct elective representation on the Board of Management has been expressly based upon certain allegations contained in a statement that was issued by the medical staff to the governors in June, 1900, and inasmuch as it would be impossible to test the accuracy of such allegations at a meeting of the governors, it is hereby resolved that an independent inquiry into the accuracy of these allegations ought to precede any reconsideration of the demand of the medical staff."

This motion rested upon an absolutely false basis, for it was notorious that the staff had made repeated requests for representation on the Board many years before the statement to the governors was issued. The motion was proposed, in a speech which was far from conciliatory, by Mr. GEORGE W. E. RUSSELL, who did his best to make historical fact fit his conception of the case. It was seconded by Mr. FRANK CAPEL, another member of the Board. An amendment was at once moved by Mr. MELVILL GREEN, a gentleman to whom the other governors of the hospital owe a deep debt of gratitude for his persistent and single-minded advocacy in behalf of the best interests of the charity. The amendment was—

"That a full and independent inquiry be at once instituted by the governors into the statement issued by the medical staff in June, 1900; the facility of intercommunication between the medical staff and the Board, including the demand of the former for direct representation on the Board; the position, functions, and acts of the secretary-director; and the constitution, rules, and management of the hospital generally."

This amendment was seconded by Sir JAMES CRICHTON BROWNE, who warned the Board that the medical press and the medical profession completely endorsed the action of the staff, while he warmly repudiated the absurd statements that medical influence on the Board would convert the hospital into a mere scientific laboratory. Of course, the staff were

strongly in favour of the amendment. Now came the surprise of the meeting. Battle was in the air, when Mr. BOWER, the solicitor to the Board, and himself a governor, announced that the Board would accept the amendment.

The amendment was accordingly put as a substantive motion and carried unanimously. A strong committee of governors and subscribers was at once appointed to choose a committee of inquiry, and this committee was instructed to place upon such committee of inquiry at least one physician or surgeon, one eminent lawyer, one man engaged in commercial or financial pursuits, one man (not a medical man) experienced in hospital management, and one other person. It was agreed to empower the committee to conduct the inquiry as the members may think fit, authorising them to request the Board and the staff to employ counsel if the committee of inquiry think necessary and to provide that all necessary and proper expenses of the inquiry shall be borne by the hospital funds. We congratulate the medical staff on at last obtaining the just and impartial inquiry for which they have been strenuously contending so long, and we congratulate the hospital on the prospect that it has of having emerged from the shadow under which it has lately lain. We trust that for the future the Board will show by their loyal coöperation with the medical staff in advancing the best interests of the charity in which they should both be profoundly and equally interested, that they have bidden a permanent farewell to the somewhat tortuous methods upon which it has been the duty of THE LANCET to reflect. For then the hospital, which must have suffered financially, and also in its power of ministering to the wants of a peculiarly afflicted and very numerous class, will soon recover the ground which it may have lost, and with a cordially coöperating Board and medical staff constantly in direct touch with each other will enter on a period of even enhanced prosperity.

Annotations.

"Ne quid nimis."

FOR THE BENEFIT OF SHOP ASSISTANTS.

A GLANCE at the legislative proposals of private Members of Parliament is often instructive and interesting, even though these proposals possibly, and, indeed, probably, may never become law. Among those recently introduced in the House of Commons we note one which is prompted by a desire to promote the health of a section of the community, and which, if it were to come within measurable distance of being passed, would probably excite considerable interest in that section and among those persons most intimately connected with it. One of its provisions meets with our cordial approval. It orders that "every shop shall be provided with sufficient and suitable accommodation in the way of sanitary conveniences, having regard to the number of persons employed there, and also, where persons of both sexes are employed, or intended to be employed, with separate accommodation for persons of each sex," and it institutes a penalty of not more than £5 for breaches of this regulation. No one can gainsay that the preservation of health and decency is a proper subject of legislative interference. All employers ought to provide that the work of those who serve them in any capacity should be done in perfectly wholesome surroundings and many employers other than shopkeepers neglect in this respect a duty which the law might well enforce upon them. In other particulars the Bill which we are criticising contains proposals as to which there may fairly be differences of opinion, differences which may easily be caused by the varying conditions in which the business of shops is carried on. These refer principally to the hours of labour. It is proposed that all shops shall be closed on one day in each week at or before one o'clock, an arrangement which would no doubt be welcomed by assistants desirous of attending football matches, morning performances at theatres, and otherwise amusing themselves, while on three other days in the week seven is to be the latest hour for closing, and upon the other two week-days nine and ten o'clock respectively. The number of hours to be worked in the week is fixed at 60, including meal-times, while an hour in the day is to be devoted to dinner and half an hour to tea. There are other regulations to limit work after closing time and there is a section which enacts that a child under the age of 14 years shall not be employed in or about a shop. The precise limitation of this last provision would presumably be ascertained by degrees after prosecutions. It hardly, however, seems to us necessary that a child under 14 years should be useless to parents or to neighbours should it be desired to find the child employment "in or about a shop." Apparently, however, the Bill would make all such employment, even by parents, illegal, although existing laws, if enforced, already protect children against being employed to the detriment of their education and against being treated with cruelty and oppression. With regard to the employment of children, the shortening of the hours during which shops may be kept open, and the whole question of shop work, we may point out generally that shop work is apparently still a popular form of employment with young people and that there is no sign that the hardships, real or imaginary, which the Bill before us seeks to diminish check the supply of shop assistants to an undesirable extent. We do not propose to criticise in detail a Bill which may never come within measurable distance of being passed. We would suggest, however, that service in shops differs widely in its severity according to places and seasons. The work may be trying at times to mind and body, but not all shops in town and country present the features of a fashionable London draper's establishment during what is known as a "sale," nor can the work done be easily compared with the work in factories, workshops, and mines which the law has recognised as a fit subject for its interference; while although shorter hours of work are undoubtedly more pleasant, especially to the young, than longer ones, it cannot be said that long hours of intermittent occupation are necessarily prejudicial to health. The question of what is or is not directly prejudicial to the health of the class sought to be benefited seems to us to be the most satisfactory test to apply to legislation of this kind which admittedly interferes with the liberty of the employer and the employed to regulate their relations by contract. We do not mean by this that the comfort or the enjoyments of the employed should be neglected, but rather that they should be regulated by other influences than that of the law—such as public opinion, the knowledge that the most considerate master will probably obtain the best workers, and the circumstances affecting individual cases. It must also be remembered that although leisure and freedom from restraint are very pleasant things, and much can be done, if leisure be granted, that is conducive to health, at the same time life is a serious matter and those who intend to work for a livelihood have to face life seriously, while it is quite possible to spend leisure unhealthily and equally possible to enjoy very little leisure and yet to remain in sound health. The difficulty, no doubt, is to frame a Bill for Parliament which will check abuses and remedy evils without at the same time injuring innocent persons unnecessarily. We

have not gone into the question of the financial welfare of the small shopkeeper who would presumably be most affected by such a measure as that to which we have called attention. We only suggest the test which should be applied to the individual clauses of Bills of this kind by the persons asked from time to time to pronounce upon them in Parliament. It might well be applied, for example, to such Bills as that to reduce the hours of miners to eight hours from bank to bank, an important change to which the House of Commons has already assented to the extent of allowing the Bill to be read a second time after a very brief discussion. The Bill dealing with the question of the early closing of shops introduced in the House of Lords by Lord Avebury is a very different measure from that which we have criticised above. It proposes to bring about the shortening of hours by the intervention of the local authority in districts and in respect of classes of shops with regard to which application shall have been made to the local authority in the manner which the Bill prescribes. It has been framed with a view to protect the health of shop assistants in those cases where it is liable to be endangered by long hours, and as such, in the experienced hands of Lord Avebury, deserves the serious consideration of Parliament.

UNSATISFACTORY VACCINATION.

THE Portsmouth Board of Guardians, and indeed Portsmouth itself, have recently been much perturbed by certain revelations as to vaccination in their union, and they are asking themselves whether, despite the fact that Portsmouth is, numerically speaking, a fairly well-vaccinated town, the population is not, *quâ* the prevention of small-pox, living in what they term a "fool's paradise." This disquietude has been brought about by Mr. H. P. Gaston, a medical member of the board of guardians, who, at a recent meeting, moved,

"That in view of the large number of children throughout the country who are inefficiently vaccinated by private practitioners (in Portsmouth it is officially estimated that they number more than 50 per cent.) this board petitions the Local Government Board to take steps that in future legislation such practitioners be compelled to vaccinate up to the same standard of efficiency as the public vaccinator, and that the Poor-law Union Association, and all boards of guardians throughout England and Wales, be asked to join in the petition."

Mr. Gaston stated that out of an average of 4760 children born annually in Portsmouth a little over 4000 per annum had been vaccinated. Of this number 1200 had been vaccinated by the public vaccinator, 800 fairly efficiently by private practitioners, and the remaining 2000 had, he alleged, been vaccinated in one place only. It is difficult to know from what source Mr. Gaston has obtained these figures as to vaccination in one place as no such return is required by the Vaccination Acts. But perhaps it is known that certain practitioners vaccinate in one place only, and that such practitioners have signed some 2000 certificates annually. Mr. Gaston regards the one-place vaccination as not only dishonest but as a disgrace to the noble profession to which he belongs, and he foresees for Portsmouth a terrible awakening in the future. Mr. Gaston had evidently the sympathy of his audience, and the motion above referred to was carried unanimously. Although we are not prepared to accept the statistics here in question without further evidence it is clear that Mr. Gaston has been instrumental in bringing to public notice in Portsmouth a very weak point in the administrative procedure of vaccination. This much-to-be-deplored practice of vaccinating in one place, and thus conveying a false sense of security to the person vaccinated, is one which all true friends of vaccination should unhesitatingly condemn. The public are unable to differentiate between vaccinations any more than they are in a position to know whether they are taking the proper dose of a drug. With them the fact of having been vaccinated confers immunity against small-pox, at least for a considerable period, but when the next wave of this disease passes over this country there may indeed, as Mr. Gaston observes, be a "rude awakening" for those who have some years previously been vaccinated in one place alone. It is quite true that such a vaccination confers protection for a time, but all evidence points to the fact that in order to confer adequate protection until revaccination is called for a scar of at least half a square inch should be produced and this scar is more easily and more safely procured by four separate insertions than by one. Those who practise this imperfect vaccination are likely to bring discredit upon the cause of vaccination and also upon themselves, and we should welcome some provision which would render such vaccination as this illegal. But the subject bristles with difficulties. In connexion with this subject of unsatisfactory vaccination we have received a communication from an American lady who has recently arrived in this country and who has had her child vaccinated in London. She alleges that the operation was performed with a domestic darning-needle which the medical practitioner did not sterilise or cleanse before using, and she asks if medical men "generally vaccinate in such a careless way over here." We trust that this lady's experience is exceptional and that the practice usually adopted is to wash the arm and to cleanse the instruments in the manner laid down by the regulations of the Local Government Board in the case of public vaccinators. There is no excuse for careless vaccination.

THE PLAGUE AT SOUTHAMPTON.

THE following are the details respecting the case of bubonic plague which is at present under observation at Southampton. The hospital ship *Simla* left Durban on Feb. 16th with invalids for Southampton, calling at Cape Town on Feb. 18th to take a few additional passengers. She arrived at Plymouth on March 12th, where it was reported that no infectious disease existed on board with the exception of two cases of enteric fever, one patient being an officer who was landed at Plymouth, and the other a member of the crew, a laundryman, who on arrival at Southampton on March 13th was removed to the isolation hospital there. In consequence of the precautions taken by the Southampton sanitary authority to have the earliest intimation of any suspicious case which might occur in the district, the authorities of the South Hants Infirmary had been requested to notify the medical officer of health should they receive into their hospital cases of glandular disease the cause of which could not be explained. On Sunday, March 17th, the house surgeon informed Mr. A. W. Harris, the medical officer of health, that he had under his care a Lascar suffering from abscess in the inguinal region who had been admitted to the hospital for operation. Mr. Harris saw the patient without delay and upon examination came to the conclusion, considering the whole of the surroundings and the history, that he should be removed to the isolation hospital for further inquiries. Suspecting that the case might prove to be plague Mr. Harris subsequently had an interview with the ship's surgeon, who informed him that the man was taken ill two days after leaving Cape Town. He had a temperature of 103·5°F., which afterwards diminished and then assumed a septicæmic character. During the early stage of his illness the man complained of a good deal of pain and tenderness over the inguinal region. The vessel on her arrival at Cape Town had not been alongside any quay or wharf, nor had the man in question been ashore. On the outward voyage of the *Simla*, however, the vessel had lain alongside the quays at Cape Town. The surgeon

stated that the case was not considered an infectious one, and he had not thought that it was plague. The patient was emaciated, weak, and distressed. A collection was made of material from the suppurating bubo and forwarded to the Local Government Board for bacteriological examination, the result of which when received confirmed the diagnosis of plague. The case is particularly interesting as showing what we believe has not happened before, the discovery of plague bacilli in pus in which large quantities of streptococci and staphylococci were present. The man is now convalescent. No other cases have occurred. All persons who had been in direct contact were isolated and were still under observation on March 26th. The nurses and others who had handled the patient were injected with Yersin's serum, and of the large number who received the injection only one complained of severe headache; the others felt no inconvenience worth speaking of. There is no direct history of infection, but there is good reason to believe that the patient, who was a baker's mate and had been in the habit of catching rats, must have obtained the infection by handling the rodents. The man's temperature at the hospital was practically normal. He had a large fluctuating swelling in the left inguinal region. He is now progressing favourably.

AEROPHAGIA OR AIR-SWALLOWING.

AT the meeting of the Société Médicale des Hôpitaux of Paris on March 1st M. Albert Mathieu and M. R. Follet communicated a paper upon a comparatively unrecognised condition—aerophagia or air-swallowing. The term *aérophagie* was first used by M. Bouveret.[1] In a hysterical young woman he observed spasmodic movements of the pharynx, during which she noisily swallowed air. From time to time the distended stomach relieved itself by a voluminous eructation of odourless gas. Later M. Pitres showed that *aérophagie* was frequent in the dyspepsia of nervous patients who were not manifestly hysterical.[2] Aerophagia is usually confounded with flatulent dyspepsia which is then treated with carminatives or antiseptics without avail. In the mild forms of aerophagia the patients complain of slight dyspeptic symptoms. Some time after meals there is a feeling of weight in the stomach and of more or less marked malaise. Soon discharges of odourless gas take place, during which there is sometimes a painful sensation of epigastric tension. As many as 30 or 40 eructations take place, and in some cases even hundreds. Such a history absolutely establishes the diagnosis. Gastric fermentation could not furnish such a quantity of gas. Pressure on certain regions, particularly on the epigastrium, causes crises of aerophagia by reflex action. The eructations succeed one another indefinitely as long as the pressure is maintained. By observing the movements of the larynx it may be seen that each eructation is preceded by a movement of deglutition. Sometimes the stomach becomes noticeably distended, sometimes not. In some cases only one eructation corresponds to four or five acts of deglutition. Other methods of producing the attacks are titillation of the pharynx and pressure on the larynx and on the spinous processes in the neighbourhood of the third dorsal vertebra In certain cases aerophagia takes a grave form: it produces vomiting, aggravates the dyspepsia, and leads to emaciation. The following cases are examples. A man, aged 23 years, had been addicted to alcohol for some years and he became dyspeptic. To relieve the discomfort which he experienced after meals he returned his food. More or less unconsciously he distended his stomach by swallowing air and in expelling this he produced regurgitations of food which sometimes lasted the whole afternoon. Soon true vomiting supervened and he became weak and emaciated. At the age of 26 years, when he entered hospital, eructations could easily be produced by pressure on the epigastrium or in the supra-sternal hollow. The patient in the second case was a very nervous woman, aged 56 years, who suffered from membranous colitis. She complained of interminable noisy eructations which came on after meals. The abdomen was relaxed, there was ptosis of the liver, and the gastric region was tender. Pressure on the epigastrium produced an attack of aerophagia with noisy eructations. The patient discovered this fact three years before when rubbing herself. It was explained to her that the eructations were simply the result of aerophagia, and rest in bed, light diet, and codeia were prescribed. Great improvement ensued. The pathogenesis of aerophagia seems to be as follows. A neurotic subject suffers from slight dyspeptic symptoms, of which he is very observant. He is excessively sensible of gastric distension and gurglings and endeavours to relieve himself by expelling gas. A movement of deglutition, usually unconscious, opens the cardiac orifice and allows an eructation, which gives relief. Unconscious aerophagia provokes a painful sensation of distension which is relieved by eructation and followed again by aerophagia. As to treatment, it is sometimes sufficient to explain to the patient the nature of the process, but in advanced cases of hysteria more severe means are necessary, at times even isolation. The dyspepsia should be treated in the usual manner. In horses aerophagia is a recognised disorder and is known to horse-dealers in France as "tic à l'air." As aerophagia, which is a neurotic disorder, is little known in French medical literature, still less recognition is to be expected in English. However, in the Edinburgh Hospital Reports of 1895 Dr. John Wyllie has described the cases of neurotic individuals who acquired the power of creating by muscular action negative pressure in the œsophagus and thus sucked air into their stomachs. In THE LANCET of August 1st, 1896, p. 304, Dr. G. A. Sutherland published a case of this kind. Dr. Wyllie terms this condition "air-sucking" and distinguishes it from air-swallowing. The case of one of Barnum's "freaks," who could by swallowing air pass rapidly from the appearance of emaciation to corpulency, may also be mentioned.[3]

ST. MARY'S HOSPITAL.

A LETTER which appeared in the daily press of March 23rd signed "Alfred de Rothschild" deals with a matter which merits the careful consideration of those who have it in their power to give. The letter recalls the fact that the executors of the late Mr. Siegfried Rudolph Zunz have awarded a sum of £25,000 to St. Mary's Hospital for the completion of the Clarence memorial wing of the hospital at Paddington, on condition that the hospital authorities shall within six months raise a further sum of £25,000, making £50,000 in all, this being the sum which the completion of the building is estimated to cost. The Clarence memorial extension was commenced nine years ago and continued until 1898, when, the basement being finished, lack of funds stopped the works. The two most important features which the new building, when completed, will present are new wards and a new home for nurses. The need for the latter will be specially understood when we state that at present all the night nurses and some of the day nurses have to be lodged in houses in the neighbourhood of the hospital. It is therefore most important that the £25,000 should be raised within the specified time or else the offer of the executors of the late Mr. Zunz will lapse, and intending donors should remember that, in the words of Mr. de Rothschild, every £1 which they give really adds £2 to

[3] THE LANCET, Feb. 12th, 1898, p. 451.

the hospital funds. London grows day by day and coincidently with its growth appears that of sickness, pain, and accident. We therefore earnestly hope that the sum necessary for St. Mary's Hospital to benefit by the Zunz bequest will be forthcoming even although the present times are hard for those who have to depend upon charity. Subscriptions may be sent to Mr. Alfred de Rothschild, the treasurer, at St. Mary's Hospital, Paddington; to the bankers of the hospital, the London and County Banking Company, Limited, Connaught-street, Edgware-road, London, W.; or to the secretary at the hospital.

THE HOMELESS IN MANCHESTER.

IT comes with something of a shock to learn that there are so many of the "submerged" in Manchester. One night about a week ago the police raided some brick kilns in Cheetham, Manchester, and apprehended 54 men and youths whom they found huddled together for warmth by the oven fires. "These wretched outcasts," as they are called in a newspaper report, were charged at the city police-court on March 13th with "sleeping out" and sentenced to terms of imprisonment varying from a day to a month. On some of them, perhaps, sympathy would be wasted, but others may be homeless without much fault of their own. In the latter case it would seem absurd to punish for the poverty that cannot provide a bed under a roof if it were not for the existence of the casual ward which theoretically is equal to all demands; but it is sufficiently unpopular to make many prefer imprisonment.

ARSENICAL POISONING BY BEER IN THE COUNTY BOROUGH OF SALFORD.

THE report of Mr. C. H. Tattersall, the medical officer of health of the county borough of Salford, has been printed and it is of special interest as dealing with that area in which the remarkable and now happily historic outbreak of arsenical poisoning by beer occurred. The report includes Professor Delépine's report on the chemical investigation and Mr. Tattersall has added Dr. E. S. Reynolds's account of the clinical symptoms which appeared in THE LANCET of Jan. 19th, 1901, p. 166, while some valuable information supplied by brewers, sugar manufacturers, acid manufacturers, and maltsters is appended. Professor Delépine arrives at conclusions which are already well known—namely, that the outbreak was due to a toxic amount of arsenious acid or arsenites in the beer consumed, that the toxic amount of arsenious acid was derived from brewing-sugars, and that the arsenic present in the sugars was due to the use of impure sulphuric acid manufactured from arsenical pyrites. He considers that when beer, sound or otherwise, does not contain more than one-hundredth of a grain of arsenic per gallon in the form of arsenious acid or of an arsenite it is probably quite a safe drink. When regard is had to the wide distribution of arsenic in nature and of the probability of its normal occurrence in food products in minute amount some definite limit should be laid down as to what may be regarded as a poisonous quantity. Mr. Tattersall suggests that it would be unreasonable to forbid the use of substitutes, providing that some means are devised by which the carelessness of one or more individuals can be prevented from endangering the lives and health of the public. At the same time, it should be recognised that any person replacing a natural substance by a manufactured article in the preparation of any foodstuffs takes upon himself the responsibility of seeing that no injury should ever result from such substitution. Mr. Tattersall holds, further, that the Food and Drugs Act should be amended so as to make the contamination of foodstuffs with poisonous matter in appreciable quantity, whether to a dangerous extent or not, and whether to the knowledge of the seller or not, an offence within the meaning of the Act, as it is obvious that the presence of a poison in a small quantity is often an indication that there is distinct danger of a dangerous quantity being introduced at any time. Lastly, Mr. Tattersall points out that one of the lessons of the outbreak is that some improvement should be made in the arrangements for the notification to the health authorities of outbreaks of disease, and that there is urgent need for some provision whereby regularly scientific investigation into the constitution of foodstuffs and their adulterants can be carried on continuously. Apart from beer these are points which the Royal Commission on Arsenic Poisoning were appointed expressly to inquire into with a view to better and more protective legislation.

A LOW ESTIMATE OF SANITARY MEDICINE.

THE sanitary authority of Axminster has distinguished itself by devising a new principle for selecting candidates for the office of medical officer of health. The principle is that of accepting the lowest tender. The applicants for the office were asked to name their terms and the appointment was given to the gentleman who asked least for his services. Save as a reward of possible modesty this seems to us an entirely unworthy procedure, raising the strongest doubt as to the fitness of the sanitary authority for the discharge of its responsible duties. The function of such an authority is to save its constituents from preventable disease and death, and the notion that this function is discharged by electing the medical man who charges least for his services is not one which we should like to apply to a dairyman or a druggist. We gather that the Axminster rural district includes a population of 10,000 and covers a sanitary area equal to 64½ square miles, for which the late medical officer of health received £45 per annum, equal to 1*d*. per head of the population, or ¼*d*. per acre, or 14*s*. per square mile. The late medical officer of health complained that he had held the office for 13 years and obtained no notice of the termination of his engagement. The ethics of this remarkable procedure on the part of the authority are of a piece with the intelligence which it had displayed and they should be duly studied by the Local Government Board. The interest of medical officers of health and of the population alike requires that appointments should be made on very different principles.

HYDROGEN A NORMAL CONSTITUENT OF THE AIR.

THERE seems little room for doubt that hydrogen is a normal constituent of the air to the extent of two in 10,000 parts by volume. Normal air, therefore, contains hydrogen to the extent of about one-half of the normal amount of the carbonic acid. The difficulty of detecting and estimating hydrogen in such a large volume of air would account for the fact that its presence hitherto in the atmosphere has not been determined for certain. This difficulty has been overcome by that untiring investigator, M. Gautier of Paris, and his success has led to some interesting revelations. It should be remarked, however, that Professor Liveing and Professor Dewar in their experiments on the liquefaction of air obtained a fraction which consisted of nearly one-half hydrogen and which by well-known means was made to explode. M. Gautier in his researches relied upon combustion methods, which were carried out with remarkable precision, and these demonstrated the presence in addition to hydrogen of hydrocarbons, at any rate in town air and country air. The hydrocarbons diminished in air taken from the region of mountain heights and far out at sea, but even at these places the hydrogen remained approximately two parts per 10,000. The air of

Paris contained, in addition to hydrogen, marsh gas to the extent of 2·2 parts per 10,000 with traces of carbon monoxide. During the investigation it was shown that in the absence of vegetation and soil the proportion of marsh gas diminished. Thus in mountain air the quantity found was 2·19 volumes per 100,000, as against 11·3 for the air of forests and 22·6 for the air of Paris; while out at sea the air is free from hydrocarbons but still contains two volumes of free hydrogen in 10,000. Hydrogen would therefore appear to be a constant constituent of the air. The origin of the hydrogen is undoubtedly geological and so also, in a measure, is the marsh gas. Methane is often evolved from many soils and from coal and other minerals, while hydrogen, it is well known, is occluded in rocks. It is interesting to speculate whether the hydrogen would accumulate in the upper strata of the air or as to whether the force of gravity of the earth would be sufficient to chain such light elements as helion and hydrogen to its surface. Some hold that their escape would be possible, and in accordance with this view there would be a constant stream of the light gaseous elements from this earth into inter-stellar space.

THE EPIDEMIC OF SMALL-POX AT GLASGOW.

No section of the public watches the contest with small-pox in Glasgow with more interest than does the medical profession, and there is no feature of that contest more interesting to its members than the call upon all practitioners to come to the help of the authorities in a house-to-house visitation with a view to the immediate revaccination of all un-revaccinated persons and *a fortiori*, of course, the vaccination of the unvaccinated. There is a certain red-tapeism in the arrangements for public vaccination which is eminently out of place at a moment when Glasgow is threatened with the gravest inconvenience and loss from a raging epidemic. That revaccination should be recognised only when done at certain stations by a few selected practitioners is a very doubtful plan for effecting the revaccination of a large community. We can only rejoice that the authorities of Glasgow have broken through this ritual and have taken into their service every willing practitioner. It is a matter of satisfaction, too, that the call of the Lord Provost has been responded to promptly by 200 practitioners who for the modest—too modest—fee of half-a-crown are to visit the homes of the people and to offer revaccination to them. The medical profession might have sulked in its tents. It might have given the anti-vaccinationists their turn and have brought down on them the just indignation of a misguided community in their suffering from disregard of the plainest teaching of experience and of medical science. But that is not the manner of the medical profession. And we can only trust that its whole energy and interest will for the next few weeks be devoted to this supreme effort to save a great city, which in many ways of sanitation has set an example to the United Kingdom from the natural effects of its own improvidence, assisted by lax and imperfect legislation. We look to this army of medical volunteers for more than a perfunctory discharge of its great duties. They will have a great opportunity of overcoming prejudice and of removing ignorance. They are performing an operation which even Leicester authorities do not despise in their officials and which *for more than 50 years sufficed to protect every nurse and other official of the small-pox hospital of London from the dire disease*. Of course, the operation in this case was done well. It was done so as to "take," and until revaccination "takes" it cannot be said to have been done. Moreover, it is possible now to do it with such precautions of cleanliness and antisepticism as to reduce the soreness and inflammation of the process to a minimum. The use of aseptic instruments, ablution of the skin with soap-and-water, followed by cleansing with an antiseptic solution, should precede the punctures which in no case should be less than four. We gather from a writer in one of the papers that some revaccinated persons say that they would prefer small-pox! While in favour of all reasonable measures to minimise temporary inconvenience we ask each person to look at the alternatives, and especially at the 200 actual deaths of those who have already paid the penalty of neglect of a sure safeguard.

ACUTE CEREBRAL DEGENERATION SIMULATING MENINGITIS.

PROFESSOR W. G. SPILLER of the Philadelphia Polyclinic has published in the March number of the *Journal of Nervous and Mental Diseases* a case of the above which is interesting because clinical symptoms of meningitis existed for six days before death and yet no signs of meningitis were found at the necropsy. On the contrary, the morbid changes which were found suggested an acute degeneration of the cerebral nerve-cells similar to those observed in amaurotic family idiocy. The case was that of a boy, aged eight years, the fifth child of his parents born at full term but after a difficult labour lasting three days. He was of feeble mental development, did not know the alphabet, and could not talk or dress himself. The senses of sight and hearing were good. He was undersized, he had some scoliosis of the spine, and he walked with a spastic gait. He was free from convulsions. He was admitted to the Training School for Feeble minded Children in Philadelphia in March, 1900. A fortnight later he appeared to be ill with pain, diarrhœa, and vomiting. He was restless, the skin was hot, and the temperature was 102° F. The pulse was rapid but there was no cardiac murmur. The lungs were normal and the liver and spleen were not enlarged. Urine was passed involuntarily. Next day he became more restless, there was abdominal rigidity, and the skin was hyperæsthetic. Food was retained. Photophobia and sluggishness of pupillary reaction followed, the abdomen was retracted, and the legs were drawn up. He grew worse after this, was delirious and very restless, and developed an erythema of the right knee and calf. There was no albuminuria. Coma supervened and the erythema increased. Only rectal feeding was now possible. The diagnosis was cerebro-spinal meningitis. The child died on the sixth day of his illness. The following conditions were observed at the necropsy. There were several purpuric spots about the thighs, knees, and arms. On removing the calvarium a large amount of cerebro-spinal fluid, tinged with blood, escaped. The cerebral hemispheres were œdematous, but there were no appearances suggesting acute meningitis. No miliary or other tubercles were present. The heart appeared to be normal except for a little paleness of the myocardium. The lungs were slightly œdematous, but crepitated and had no areas of consolidation. A few slight submucous hæmorrhages were present in the stomach and kidneys. There was a small supernumerary spleen. Microscopical examination of the brain and spinal cord showed nerve-cells in a state of acute degeneration in the anterior and posterior cornua, cranial nuclei, and cerebellar and cerebral cortex. In the cerebral cortex the giant pyramidal cells of Betz were especially degenerated and altered. The cell-bodies were swollen and rounded, many of the dendritic processes had disappeared, the chromatic granules were not to be seen except in a partially disintegrated condition immediately around the nuclei, and often the nuclei were displaced to the periphery of the cells. All the multipolar cells of the anterior cornua in the spinal cord showed these changes in a marked degree, recalling the appearances described by Hirsch and Sachs in

amaurotic family idiocy. Various short bacilli were found in the nerve-tissues. Spiller refers to another case observed by him in conjunction with Dr. J. McCarthy where similar changes were found and that, too, was in a feeble-minded child. The theory of a toxic causative agent seems to be suggested in the present instance, the disease having analogies to the meningitis serosa described by Finkelstein and Seitz, in which bacilli were found in the cerebro-spinal fluid.

THE BEER BILL.

ON the night of March 27th the Beer Bill passed its second reading in the House of Commons by the substantial majority of 112. Put shortly the Bill is intended to enable the consumer to know what he is not drinking. "Beer" is to be divided into two classes, somewhat on the logical process of dichotomy—namely, malt beer and part malt beer. Malt beer means that which is brewed from barley, malt, yeast, hops, and water. Part malt beer does not mean this. These are admirable provisions to our mind and we would fain see them extended to all classes of food. Substitutes are generally harmless and often palatable, but the consumer should know what he is getting. If, for instance, he likes to use cotton-seed oil for a salad let him do so, but he should not have cotton-seed oil palmed off upon him under the impression that he is buying olive oil.

THE COLONIAL SECRETARY AND THE SANITATION OF OUR WEST AFRICAN COLONIES.

THE unhealthiness of certain portions of the West Coast of South Africa has long been a matter of notoriety, and an enormous number of relatives and friends of the workers on that coast have had good reason to deplore the fact. So much, indeed, has the deadliness of this district been officially recognised that higher pay is awarded and longer leave granted there than is the case elsewhere. But if the chambers of commerce of London, Manchester, and Liverpool, assisted by the young but vigorous Liverpool School of Tropical Medicine, have their way all this will soon become matter of history. Mr. Chamberlain has lent more than a sympathetic ear to these bodies, which waited upon him recently at the Colonial Office, and he has propounded a scheme which should bring forth in one or another fashion an abundant harvest. The deputation had apparently a little scheme of its own, but such scheme did not in its entirety commend itself to Mr. Chamberlain's statesmanlike mind. Clearly, in the view of that mind, the scientific expert is an admirable individual but perhaps a little too given to utopian ideas. By all means let the scientific expert be the mainspring of an expedition to the West Coast colonies, but let his ideals be applied by the representatives of the several chambers of commerce who will accompany the expert, and let there also be a representative of the Colonial Office who shall, as it were, focus the information obtained and bring it back for the benefit of the Colonial Office. This was, in effect, Mr. Chamberlain's scheme, and it is apparently soon to be carried into effect. With a proposal to make a "house-to-house" inspection of our West African colonies Mr. Chamberlain was not in entire accord. He saw the danger of too sudden a change which might work incalculable harm and there is no doubt that a gradual adaptation is a wise method. There is, however, one particular in which we venture to differ both from the Colonial Secretary and from the deputation. As we understand it, it is proposed to have but one sanitary adviser upon the Commission. We would suggest, however, that, having regard to the importance of ascertaining, as far as may be possible, the causes which are responsible for the undoubted unhealthiness of the districts concerned, a trained epidemiologist used to etiological methods should be included. With the view of meeting Mr. Chamberlain's desire to obtain an estimate of the necessary cost of the proposed reforms the services of a sanitary engineer versed in estimating the cost, and devising schemes, of water-supply and sewerage are also required. Both of these gentlemen should be selected with the greatest care, and the importance of their working amicably together should not be lost sight of. This proposal would still leave the scientific element in a decided minority, and hence there would be no fear that the practical side of the question would be overlooked.

A MEMORIAL TO THE LATE DR. LEECH.

A STRONG desire has been expressed to honour in some permanent form the memory of the late Professor D. J. Leech, and many of his friends have offered to help in the furtherance of a suitable scheme for this purpose. Those who were in the confidence of their late friend believe that such a memorial could take no better form than that of carrying out a project in which Dr. Leech was deeply interested, and with which he intended to occupy himself had he lived a few years longer—namely, the provision of an endowment for the professorship of materia medica and therapeutics in the Owens College, a chair which he himself occupied for nearly 20 years with much distinction. Owing to his unexpected death last summer at the comparatively early age of 60, Dr. Leech was unable to fulfil his intentions in such a way as to enable the chair to be founded at once; but in his will he provided for the future by leaving a sum of money which will ultimately be available for the endowment of the chair. It is now the wish of the late Professor Leech's friends and colleagues to provide for the immediate endowment of the professorship, and to associate it with his name. The Council of Owens College have decided that the chair shall be called the Leech Professorship of Materia Medica and Therapeutics, and all who wish to join in the memorial are invited to subscribe. Subscriptions may be sent to Dr. E. M. Brockbanks, 3, St. Peter's-square, Manchester, honorary secretary; to Dr. J. Dreschfeld, 3, St. Peter's-square, Manchester; to Dr. D. Little, 21, St. John-street, Manchester; or to Mr. W. Whitehead, 17, Market-street, Manchester. We think that many of our readers may like to testify their appreciation of Dr. Leech's services to medicine, both scientifically as a pharmacologist and practically as a thoroughly useful member of the General Medical Council, by contributing to found a professorship to his memory in the college which he served so faithfully. About £2000 are required, upwards of one-half of which sum has already been received.

THE COAL SMOKE ABATEMENT SOCIETY.

WE have received the annual report for the year ending Dec. 31st, 1900, of the Coal Smoke Abatement Society. The society is doing most useful and admirable work, and since its formation in March, 1899, no less than 2700 observations have been made by the society's inspector on smoking chimneys in various parts of London; offences have been proved in 162 cases, and penalties have been inflicted, amounting altogether to the large sum of £750, of which many have been of small amount. During the year 1900 the inspector reported to the committee 1742 observations of offending shafts, and by order of the committee 1010 formal complaints were presented, as the nuisance was not abated, to the local vestries, borough councils, and the Port Sanitary Authority of London. In 125 cases proceedings were instituted and fines imposed amounting to £494 13s. The report also states that the owners of the numerous and increasing class of trade furnaces and chimneys have profited by the conviction of other offenders

and have taken steps to secure themselves against prosecution. We are very glad to hear this, for in the West-end of London, at any rate, it is not the factory chimney which is the chief sinner, but the chimneys belonging to such trades as bakers, restaurants, and big hotels, to say nothing of the electric lighting companies. The excuse generally put forward about not being able to get Welsh coal is no excuse at all. The section of the Public Health Act concerned with smoke says nothing about Welsh coal, but merely mentions black smoke. Fines should certainly be imposed of such magnitude as to make it obvious to the owner of an offending chimney that it will be cheaper for him to take steps to prevent such chimney vomiting filthy smoke than to run the risk of being fined. That such steps can be taken is shown by the example of the Nottingham lace manufacturers. They found that the emission of black smoke spoiled their goods, and therefore set themselves to work to find a means of curing the nuisance. This was done with such success that nowadays a smoky factory chimney in Nottingham is unknown. If this result can be attained in the case of factory chimneys it can also be secured by the expenditure of money in the case of other chimneys. We would add that the society at present has only one inspector. If it could afford to pay another the excellent work already done might be largely increased. Subscriptions will be gladly received and acknowledged by the honorary treasurer, Dr. H. A. Des Vœux, 14, Buckingham-gate, S.W.,

THE LONDON COUNTY COUNCIL WATER (PURCHASE) BILL.

MR. LONG, the President of the Local Government Board, recently received a deputation from the London County Council on the subject of the London water-supply. He may have felt that as a Minister in a strong Government it would have been an abuse of power not to receive the deputation, but in the circumstances he would have been justified in so doing, and his action would not have been mistaken for intolerance by those who really understand the questions at issue. Mr. Long then definitely declined to support the pretensions of the London County Council to legislate for "Water London" in a manner directly opposed to the interests and to the wishes of a majority of the public authorities who represent the extra-metropolitan districts. After this the London County Council cannot be surprised that their Water Bill met with ill success in the House last Tuesday. The interests of the people of London will be best guarded by the metropolitan boroughs and by the City of London. The City representatives have already spoken. The borough councils will undoubtedly give their attention to the matter. We regret that the London County Council persist in wasting the ratepayers' money in useless Parliamentary proceedings.

DANGEROUS FLANNELETTE.

OUR attention has more than once been drawn to the extreme inflammability of what is a very popular article of clothing in the cold season of the year—namely, flannelette. As is well known, it is a soft fluffy fabric and is used largely as a material for making nightshirts on account of its warmth, especially for children. We have nothing to say against its qualities of keeping the body in comfort and warmth, but that it is a dangerous material for the purpose has been very sadly shown in more than one instance. It ignites with the most dangerous ease, burning with a hot bluish flame not unlike the flame of burning alcohol, and once alight it is well-nigh impossible to extinguish it. The latest disaster arising from the use of this material was in the case of a child, aged six years. The poor little fellow was clothed in a flannelette nightdress, and by some means or other he had too nearly approached a gas stove, with the result that he was soon enveloped in flames. He evidently had been left alone, for his mother had rushed from another room to his assistance on hearing his screams. He was so badly burned that he died on the following day. We have tested this material again and again, always with the same result. It takes fire instantly owing to the fluffy and porous nature of the material, a hot blue flame shooting along the surface and increasing most rapidly in size and in intensity. It cannot be too widely known that flannelette is a most dangerously inflammable material, and that great care needs to be taken to prevent it from coming anywhere near a fire, candle, or gas flame. In any case, whatever the clothing may be, children should always be protected from such a possibility by adopting fire-guards. There is no doubt that when once flannelette is ignited the fire can only be put out and a horrible sequel prevented with the greatest difficulty. The life of the person dressed in it, according to the experience of such cases, is hardly ever saved, than which it is difficult to imagine a worse indictment against flannelette.

THE reports for the year 1900 of the Committee of Management and of the Medical Committee of the Dental Hospital of London were considered at the annual general meeting of the governors held at the new hospital on March 28th. From the former report it appears that the new Dental Hospital has been erected at a cost of nearly £50,000, exclusive of the sum of £42,000 paid for the site. The old building has been sold for £18,500. From the latter report it appears that no less than 69,176 cases were attended to at the hospital during the year, of which 28,752 required operations which were performed under anæsthetics. This is a steady increase upon previous records.

THREE telegrams, dated March 20th, have been received at the Colonial Office from the officer administering the Government of Western Australia. The first states that up to date the following cases of plague had occurred:—in whites eight cases, seven being in adults and one in a child, with no deaths, one Chinese male who died; total cases nine. In addition a very suspicious death had occurred of a white man, which death, telegram No. 3 states, was pronounced to be due to plague. Telegram No. 2 states that the governor was confident that owing to the rigorous measures adopted the plague would shortly be stamped out.

ADVANTAGE is being taken of the expected visit of their Royal Highnesses the Duke and Duchess of Cornwall and York to New Zealand to hold a gigantic bazaar at Wellington, the capital, in aid of a home for incurables. Lady Douglas, who will preside over the Empire Stall, has started a memorial fund with the object of adding a wing to this home, to be called the "Empire Memorial Wing" in honour of the brave New Zealanders who have lost their lives in South Africa in defence of their sovereign and country.

AT the annual general meeting of the Medical Graduates' College and Polyclinic on March 26th a considerable portion of the time was occupied in a discussion raised by Dr. F. W. W. Goodsall on "The Really Dangerous Position Financially of the College." On this point the honorary officials spoke at length, with the result that the council's report and balance sheet were duly passed.

A TELEGRAM from the Governor of the Cape of Good Hope, Sir W. F. Hely Hutchinson, received at the Colonial Office on March 25th, states that for the week ending March 23rd there were admitted 46 cases of plague. The deaths numbered 21, the suspects three, and "contacts" 394.

THE official programme of the proceedings to take place at

the British Congress on Tuberculosis, to be held in London this year from July 22nd to July 26th, has just been issued. We have no space this week in which to make more than the bare announcement.

GUY'S HOSPITAL has received a grant of £2000 from the Goldsmiths' Company towards the special requirements of the hospital, which include a building fund of £180,000.

THE MANAGEMENT OF HOME MILITARY HOSPITALS.

BY SURGEON-CAPTAIN W. PUGIN THORNTON,
ROYAL EAST KENT YEOMANRY CAVALRY.

THE management of military hospitals in South Africa, judged mostly by civilian eyes, has of late exercised many minds, so much so that a Royal Commission of inquiry was granted to examine into all the points at issue. Having acted for a year during the Boer war as medical officer at a station hospital in England containing more than 100 beds it may be of interest if I point out some of the instances in which I believe improvements on the present home system might be made.

In the first place, it should be the rule of the authorities of the Army Medical Department that no medical officer should be put in charge of a station hospital unless they were satisfied that his knowledge of medical and surgical practice was thoroughly sound and fully up to date. Should an officer not be considered fit for the post of senior medical officer then he should not be given rank above a major, or even a captain, and should be allowed to retire on full pension if he so desired.

The senior medical officer (S.M.O.) in charge of a military hospital has every morning to send a certain number of sick soldiers into the wards. Each one has a diet sheet at the head of his bed, which has a space filled in with the title of the complaint which the senior medical officer has diagnosed the man to be suffering from. Should the junior medical officer under whose care the sick soldier is placed not agree with the diagnosis of his senior he cannot alter it without referring the matter to him. This is all right if it occurs only once or twice, but frequent references to the senior medical officer are apt to become, to say the least, tedious. And if he points out to the senior medical officer the faulty diagnosis and the latter does not agree to change the title of the disease nothing more can be done by the junior medical officer. Should he persist, however, in drawing attention to a number of cases he will be sure to be told that he is impertinent, that he is to mind his own business, and that the senior medical officer sees no occasion to alter his opinions.

When cases of faulty diagnosis occur through the want of sufficient training on the part of the senior medical officer, such palpable errors not only cause opprobrium to fall upon the profession, but give much dissatisfaction to those connected with the work of the hospital. Undoubtedly the senior medical officer should be reasonably perfect in his work, so that junior officers can appreciate his work with satisfaction and be able to appeal to him with a feeling of safety in any medical or surgical dilemma, and also—and this is not the least important item—that the soldier can rely upon the treatment of his malady being safe and likely to be beneficial.

Of course we are all liable to make mistakes. I made a glorious one during my work in the station hospital by thinking that the rash which mostly covered a man's body was small-pox modified by vaccination. It was a case of iodine rash—and this rash I had caused myself by having frequently painted a quantity of iodine on his leg and neck. I proved this by bringing out the rash a second time. I felt so confident at first that it was a case of small-pox (there were nine cases in the neighbourhood to frighten me which had been diagnosed as chicken-pox), the man having slight fever for a day, that I vaccinated all in the hospital. Certainly this was a mistake on the right side, for to overlook a case of small-pox is a terrible calamity. But to make blunders continually is another matter.

The best suggestion which I can offer is that the Army Medical Department should assist army medical officers to continue their medical and surgical studies from the time that they enter the service to the day on which they are promoted to the rank of lieutenant-colonel. If every medical officer spent a month in every possible year up to the date of his promotion to lieutenant-colonel at a large general hospital, possibly with school attached, then by the time his turn came to take charge of a station hospital he should be reasonably perfect in his work.

Medical officers should not be bothered with examinations. Often examinations do not show the practical worth of a man. Rather let a surgeon from year to year be judged by his work. Of course, it should be insisted upon that medical officers did not waste their opportunities of gaining fresh knowledge during the annual months in London or elsewhere. Professors of the civil hospitals in consideration of the fees paid would ensure that there was no waste of time, reporting if the post-graduate's application to work was not satisfactory. It is universally acknowledged that a medical man acquires knowledge far more readily and of greater use after he is qualified than he does when he is a student. If year by year a medical officer, after two or three such months of general work, varied his subjects, one year attending a lunatic asylum (very necessary for the quick appreciation of soldiers pretending to be insane), another year an eye hospital, another year a throat and ear hospital, another year a hospital for women and children (for the sake of those he has of necessity to look after), another year at Netley Hospital, and would give some time to the work of a medical officer of health, then the frequent statement that an army surgeon knows "next to nothing" would be a saying of the past. They would after such varied study, with the military hospitals in which to amplify their work, become superior in medical and surgical knowledge to their brethren in civil life, and the day would come that no combatant officer would ever want to call in a civilian practitioner to attend his family, so great would be his faith in his brother officer. It is presumed that special pay would be granted to medical officers during these annual months, and that all the civil hospital fees would be paid for them, also that weekly medical journals would be provided. Perusal of these greatly helps to keep one fresh in professional knowledge. Medical officers should also be encouraged to report "interesting" cases in medical journals. Doing so increases a man's accuracy in, and his love for, his work, besides often putting before him or other members of the profession some knowledge which they have not had the opportunity of acquiring. Every station hospital, also, should have a fixed table with a good microscope ready for immediate use, and a complete case for testing fluids.

The diets for soldiers in hospital who are able to eat solid food are known by the names of "chicken," "convalescent," "roast" (which includes joint, chop, or steak), and "varied." The "chicken" diet allows for dinner half a chicken, which must not weigh less than eight ounces and the "convalescent" diet allows 10 ounces of meat (with bone), and each has four ounces of bread and eight ounces of potatoes. The "convalescent" diet, in addition, has 15 ounces of soup, which contains four ounces of mixed vegetables. The "roast" diet has its bread increased to six ounces, and in addition to the eight ounces of potatoes has four ounces of vegetables. Each of these three diets gives a very good dinner, but a far better one is the "varied" diet. This has 15 ounces of roast or stewed meat (with bone), six ounces of bread, 14 ounces of potatoes, and six ounces of vegetables. A curious regulation with regard to this latter diet is that no extras are allowed, so that the medical officer must not put upon the diet sheet such things as soda water, eggs, or custard pudding &c. Should he do so, perhaps desiring his patient to have a drink when he is thirsty or something to eat in the night, he may be charged with the cost of each extra ordered notwithstanding that he has written a history of the case. Should the medical officer order extras with other diets (say, a custard pudding with the "convalescent" diet) then the regulation is that he must write a history in the case-book, and note upon a special blank space on the diet sheet the page in the case-book on which he had written a history. Evidently by this compulsory writing of a history it looks as if the intention was to deter medical officers from giving extras, however necessary they might consider them to be. Of course, such serious cases as enteric fever, and so on, should have histories written, but it is waste of time to write long notes on all sorts of cases. If the existing regulation is solely for the

purpose of stopping extra nourishment being given, I have no hesitation in saying that the regulation serves its purpose, and is not an ennobling one for the service.

In relation to the question of ordering extras it is found that in nine cases out of ten a sick soldier who is able to enjoy his food eats the whole of his bread-and-butter at breakfast and dinner meals, leaving only the pint of tea for his last meal. It is the custom to serve the bread-and-butter rations in the morning. During an epidemic of influenza, lasting from November, 1899, to the spring of 1900, I had over 500 cases of this disease passing through my hands, a few of them ending fatally. I found it desirable in every case to give stimulants (in the shape of egg-flip), never knowing during that epidemic how serious each man's illness might be. To get over the difficulty of writing more than 500 medical histories, and to save the waste of time, I used to mark the diet sheets with the number of a certain page in the case-book. On this page I had written the history of one case of influenza, adding to my notes that, as by far the greater number of the cases of this disease were nearly alike, I should make this one history stand good for the greater number. It was doubtless very wicked of me, but it was consolatory to be thus able to save my regimental conscience and at the same time to be able to give more time to more useful work. It may be hoped that before long the Army Medical Department authorities may see their way to trusting medical officers more fully, allowing them to give extras when they consider it desirable and not forcing them to write histories of cases which are of no use to anybody, only being, if waded through, a waste of time to read. I acknowledge that every hospital surgeon is liable at times to be guilty of ordering excessive diets for his patients. It is so in civil hospitals. But, I think, experience shows that it is only necessary for attention to be drawn to the fact and the extravagance will cease. If treated as gentlemen men will, of course, behave as gentlemen. It will be quite time enough to use such measures as ordering histories to be written when a chronic offender will not pay attention to his senior officer's warning.

The breakfast and tea meals with each of the four mentioned diets are the same. They consist of a pint of tea, six ounces of bread, and half an ounce of butter. Between tea and breakfast there is no other meal, and therefore the sick soldier is 14 hours without food. Considering the scantiness of the tea meal (supper) this is much too long a time. If the tea was made more substantial by adding sausages alternately with eggs, &c., and given at 6 P.M. instead of at from 4.30 P.M. to 5 P.M., then the man would be more fitted after his night's sleep to wait until the eight o'clock breakfast. I have often had sick soldiers complain of great feeling of emptiness in the night. No wonder, especially with those who have eaten all their bread by the middle of the day. The breakfast, too, is a very poor one. I should like to see it enlarged by oatmeal porridge alternately with corned beef or cold bacon, &c., and the quantity of the bread-and-butter increased. In gaol we give prisoners more satisfying breakfasts and suppers than we do these soldier patients, for the former have eight ounces of bread and a pint of porridge with each meal.

There is a blot in the regulation regarding the ordering of diets, and that is that if a meat diet has been marked on the sheet the previous day, as the custom is, and the soldier has an attack of fever or colic, &c., the diet cannot be altered for one of milk or of beef tea. At any rate, if it is so altered—and it is most desirable that it should be—then there is a great hullabaloo because the articles of diet have been requisitioned the day before and the diet sheets have also to be altered in the office. The remedy should be to allow a sufficient quantity of milk to be given to the extra sick soldier, putting his unused diet on a casualty list. Undoubtedly it is a waste of time daily to have to write down the diet a soldier is to have, when no alteration perhaps is made for two or three weeks. In civil hospitals a blank sheet is used, and when a change of diet is thought desirable the fresh diet is written down with the date against it, and thus time is saved.

Soldiers who come to the hospital for medical treatment are sometimes sent into what is known as the "detained ward." This is done when probably a man will be well enough to return to duty the next day, or when the medical officer is doubtful if his illness will be of a nature to necessitate his being made a hospital patient. The order is that a soldier should not be kept in a detained ward for more than 24 hours, but I have known him to remain there for four days. It is often a great convenience to detain a sick man for more than one day. As long as a soldier is thus detained his meals are not supplied by the hospital, but his rations are brought up from the barracks uncooked, the cooking being done in the hospital kitchen. The practice is the same with regard to rations given on the first day that a soldier is admitted into hospital. He is supposed to bring his uncooked rations with him which are to be cooked in the hospital kitchen. But this, as in the case of the detained soldier, is very rarely, if ever, done and the consequence is that the man's meals for the first day are brought up cooked by the orderly of the sick soldier's barrack-room. After a journey, which may be long, we may be sure that the food is scarcely in a suitable condition for a sick man. It must be granted also, of course, that the illness the soldier is suffering from is suitable to the food, and not the food to the illness, which requires no Euclidian demonstration. The dietary arrangements for the first day a soldier is in hospital, or during the time he is in the detained ward, are bad. It should be that in either case the man is fed entirely from the hospital kitchen with a diet ordered by the medical officer. This bad arrangement for the detained ward was carried out in South Africa, for a letter published in the *Times* a short time back from an Imperial Yeoman to his father bitterly complained of his diet during the days he was in the detained ward of his hospital.

With regard to the healthy hard-worked soldier in barracks his dinners are good, but his breakfast and tea (supper) meals leave something, medically speaking, to be desired. These meals vary considerably. For instance, in one regiment there is for breakfast on Sunday boiled bacon besides the tea and bread-and-butter, but nothing extra on the other days of the week. Another regiment on Sunday has brawn, on Monday salmon, on Wednesday sardines, on Friday cheese, and on Saturday bacon. In both of these regiments when they have something extra for breakfast they only have the tea and bread-and-butter for supper. On the days when they have nothing extra for breakfast they have for supper either potted meats, corned beef, tomatoes, sardines, fish, brawn, tinned salmon, kippers, jam, or golden syrup. It would be wiser if at each of these meals they had steak, liver-and-bacon, or Irish stew, &c. I believe that their funds would allow of more substantial food if economy was better studied. Latterly it has been arranged that every soldier should be able to procure a cup of coffee and a biscuit after 6 A.M., in some regiments free of charge, in others at a ½*d.* each. This shows that the desirability and necessity of increasing the amount of sustenance have been seen. It would also be wiser if for breakfast a full half hour was given instead of it being rushed through in ten minutes or a quarter of an hour.

Kitchens should be better fitted up than they are, complete sets of cooking utensils being provided. Kitchens are very often badly kept, the utensils being dirty. Diarrhœa is caused sometimes from foul saucepans, but not always, or the station hospital would be in greater request. At depôts it seems to me that permanent cooks should be kept. This is the order given elsewhere. Permanent cooks are, of course, better cooks than the odd men; they keep their places and utensils in better order and they form a school of cookery for the youngsters.

Another boon might, and many say it should be, granted. The daily pay of a soldier in the infantry is 1*s.* with 3*d.* for mess allowance, and for the cavalry man 1*s.* 2*d.* with 3*d.* for mess allowance. (This 3*d.* of the last two years is a great improvement.) At the present time a soldier in hospital has 7*d.* a day deducted from his pay for his food, besides losing the 3*d.* which outside he has for mess allowance. This deduction must be intended somewhat to stop the soldier malingering—not that it often succeeds. In special cases this stoppage of pay for food is remitted, for instance, when a soldier has been admitted for an injury which occurred on duty. Then there has to be a court of inquiry, whose finding has to be submitted to the general officer commanding the district. If this officer approves, the whole or half of the stoppages are remitted to the soldier. Deducting 10*d.* a day from the pay of a bachelor soldier is not so great a hardship as it is in the case of a married one. A married soldier's home during his sickness has to be kept up, and his wife and children have to be fed. When the man is on duty rations are issued to the family, but when he is sick no food is granted to his wife and children. The hand of disciplinary regulations falls heavily upon them for the illness

of the husband and father. How they manage it is hard to say. Living must be done at a starvation rate. The misery of the family is, I should think, unwarrantably great. I know what the sick soldier's misery is and that this worrying on his part, putting it mildly, does not help his recovery. It seems to me that Government should act as a good master does to his servant, paying full wages during sickness. There is more reason for the Government doing so, for it never has to fill the man's place during the time he is sick. Or, putting the argument in another way, Government could take upon itself to act towards the soldier as a sick club does with a subscribing labourer. If a soldier "goes sick" without sufficient reason it can be left to the military surgeons to put a stop to his malingering, and the malingerer could be charged full price for his food for the time he has been in hospital. In the sister service no portion of the sailor's pay is deducted for the first month. After that time up to three months he loses 10*d*. a day out of 1*s*. 7*d*.

I have a strong feeling of regret at the continuous enforced economy in every department of the hospital. This practice of economy is almost miserly. Certainly it is harmful. Probably it is in consequence of the poorness of the grant for carrying on the working of military hospitals. During my time of work at the station hospitals I often had to make complaints that the baths were not supplied with hot water, and frequently I found that the cold water had been turned off because attention had been drawn from head-quarters to the high amount of the city water-rates. Now, to ensure soldiers being clean before they go to bed in the hospital wards, and to keep them clean, there must be plenty of hot water for their use, and, therefore, the water-supply should not be niggardly. It is false economy, it is generally allowed to lead to dirtiness, and also that dirtiness breeds unhealthiness. The same scarcity of supply can be said regarding the quantity of gas allowed to be consumed in the wards, officers' rooms, and offices of the station hospital. There was repeatedly an insufficient light for me to read or write by, and certainly too poor a light for operating by. I used to borrow a duplex lamp from the neighbouring civil prison, of which I am surgeon, when I wanted a light sufficiently strong for such special work as the examination of ears and throats. The stock of instruments allowed for a station hospital, say of over 100 beds, is too scanty. If other instruments than those kept in the surgery were required I obtained them either from the prison or from my home. Many a time I have heard the sisters complain of the short allowance of bandages, &c. Many a time I asked that an instrument and a drug I required might be written for, but I was put off with the statement that it was no good applying for them, that I should not get them, or that there would be so much correspondence on the subject that I must be good enough to manage without; and so, as I have already stated, I borrowed. The same trouble occurred with regard to drugs. The stock kept in the surgery, to my mind, is below the proper requirement. One often had greatly to fashion one's medical treatment to the collection of drugs kept in the surgery, and not to treat disease entirely with those one believed most suitable—a grand opportunity for hitting upon a new cure. Perhaps it was better for many sick men that they were left more to nature. Sometimes, however, I did bring medicines from home for use at the station hospital. One had to do this on a few occasions when the hospital supplies ran short and until the half-yearly drug supplies came in. Supplementary drug demands can be sent in, but they take about a month before being executed. One special drug I did apply for. I was told that it would not be allowed. It was Nourry's iodinated wine. This remedy saved the life of a soldier, or saved him at any rate from losing his leg from tuberculous disease of the knee and tibia which followed a wound caused by the kick of a horse. This remedy was kindly allowed by the authorities, but 19 days passed before the supply arrived, and in the meantime I had to obtain some from a local chemist at my own expense, in order that the man might be kept going. Three weeks without this drug would have been most serious for him, for it was the only one which was of service to him, and without it I believe he would have "gone the way of all flesh." It is difficult to see why the Army Medical Department cannot act in the same way as the Commissioners of Prisons. If drugs are urgently needed, sufficient quantities (to last until the contract druggist can send a supply) are obtained from a local chemist. And thus it is with all other items of necessaries for sick prisoners. The supplies are liberal, and the medical officer has a free hand in ordering them.

I may add that prisoners in gaol receive every consideration. It was said by a man's wife at Bow-street before the magistrate concerning her husband, who was in custody for desertion, that, "he prefers going to prison to paying, and says it is like going into a convalescent home. The only thing he misses is his beer." (This statement appeared in the daily papers of Nov. 10th, 1900.) There is nothing wanting for them that is desirable. It would be well, to return to the question of the management of the station hospital, if Government would extend this extreme prison liberality to the Army Medical Department, thus allowing for an improved state of things in the case of the sick soldier.

At times during my year of office as medical officer I also carried on the work of the senior medical officer during his illness, and thus of course I had an insight into the whole management of military hospitals. One of the greatest puzzles, amongst others, to me was the steward's account. It accounted by one-fiftieth of an ounce in the column for pepper, one-twentieth of an ounce for mustard, and one-eighth of an ounce for flour. The amalgam of these fractional proportions made a lovely show—a regular battle-field of figures.

The returns in the Army Medical Department are most varied and almost endless. There are daily returns, weekly returns, monthly returns, quarterly returns, half-yearly returns, and annual returns. I often wondered that the staff-sergeant at the head of the clerical department in the hospital I was working at did not lose his head and make one big return by throwing the accounts into the fire, but then he was a most excellent young fellow, and I may add that he was not only quick, neat, and correct in his clerical work, but that he was also a capital hand as hospital orderly, at bandaging, and at the first management of injuries. He was, I considered, the great mainstay of the hospital, besides being able to play cricket and football, which are most desirable relaxations for the staff. He knew all the innumerable regulations and the proper method of carrying them out. Everybody could depend upon him. What added to one's feeling of admiration for him was that in all he did he kept "straight." For a non-commissioned officer to be honest is everything. I am sure that it must be a great temptation for one in a staff sergeant's position to be dishonest, the opportunities being so great. I hope that there are many like him throughout the Army Medical Department. Were the accounts in simpler form the number of clerks could be less, and it follows that then the expense of carrying out this department would be less.

With regard to my previous remarks upon trusting more fully the medical officers, I may add that there appears to me to be a general want in the Army Medical Department of trust. This leads to certain officers not trying to do their best. It is rather the practice, it seems to me, to do as little work as possible with the least amount of trouble, and to grumble when it is being done. Of course there are other reasons, but I feel confident that this want of trust is a great item for causing discontent—and rightly so, most of us will say. My acquaintance with army medical officers is limited, but for the greater part it has given me the idea that there should be an effort on the part of the authorities to improve this class of officer. Not only, as I have pointed out, do some require a better knowledge of medicine and surgery, but the old understanding of the term "an officer and a gentleman" should be encouraged again to come into existence in every case. It would be well, I feel sure, that the pay of medical officers should be increased that a better class of hospital students should more frequently decide to enter the army. Is not a qualified medical man with the power at once to earn an income, who enters the army in a much better position than the man who enters the army as a combatant officer, if both of them at the last moment decide not to become officers in His Majesty's army? Therefore the former's pay should be proportionately greater. He is rolling two professions into one. And it should be greater, more especially as the want of medical officers has been for some years past much felt by the authorities. Added to this want the desirability of improving the class of officers for the medical corps is now recognised. The senior medical officer, besides being

"reasonably perfect in his work," should also be a gentleman in the fullest sense of the word, and one that excels in managing his fellow-men. Such being the case there would be no fear that a principal medical officer, who has charge of a district, would be unsuitable for his post, considering that he is chosen from the number of senior medical officers.

THE REPORT ON ANÆSTHETICS ISSUED BY THE BRITISH MEDICAL ASSOCIATION AND "THE LANCET" CLINICAL REPORT ON ANÆSTHETICS.

I.

A BRIEF *résumé* of the first-named report has been already placed before the readers of THE LANCET.[1] We propose in the following remarks to deal more in detail with the facts presented by it and the conclusions advanced by the committee entrusted with its preparation. Its initiative, we are told,[2] was a discussion which dealt with the importance of a clinical investigation into the action of anæsthetics. Papers were read upon the occasion insisting upon the necessity for some collective investigation into the subject. This occurred in 1891, but we must go further back to trace the true sequence of events which led to this the most recent pronouncement upon the merits and dangers of anæsthetics. All those who have studied the history of the subject will recall the publication of Dr. Snow's work, "On Chloroform and other Anæsthetics."[3] In this most meritorious book are contained accounts of experiments upon the lower animals performed to elucidate the then practically unknown physiological action of anæsthetics as well as a careful collection of the cases of human beings to whom chloroform, ether, amylene, &c., had been administered. An attempt was further made by Dr. Snow to explain such accidents, whether fatal or not, as occurred to patients by reference to the experiments detailed. Dr. Snow also collected all the records of deaths procurable from the first use of general anæsthetics and commented with great acumen upon them. Thus both an experimental and a clinical record find a place in his pages. Wakley and others had investigated the physiological action of chloroform, but the first collective attempt to study the matter owed its origin to the Royal Medical and Chirurgical Society which published its report in 1864. The major part of this report was experimental, although appendices were added which besides giving a further list of deaths dealt also with the uses and effects of chloroform and the best modes of resuscitation. The report concludes by giving a number of rules to be adopted with the view of avoiding danger during the inhalation of chloroform. Various researches of an experimental character have been made since the publication of this report, but the most important, since they led to a further clinical investigation upon the matter, were the well-known Hyderabad Commissions appointed in 1888 and 1889. Sir (then Dr.) T. Lauder Brunton represented the Editors of THE LANCET in the Second Hyderabad Report and the results accruing from the large number of experiments made were published in THE LANCET.[4] Both of these reports were initiated through the enterprise of Lieutenant-Colonel Lawrie, I.M.S., and by the munificence of H.H. the Nizam of Hyderabad. At the conclusion, however, of this purely experimental research the importance of investigating from the clinical side became apparent and the Editors of THE LANCET thereupon appointed a Special Commissioner to draw up such a report and in 1893 published[5] what was the fullest and most important clinical inquiry into the action of chloroform and other anæsthetics upon human beings which had ever up to that time been undertaken. A comparison between this report and the one just issued by the British Medical Association cannot but prove advantageous, as the two, although prepared upon different lines and with different methods and from somewhat different material, present many points in common and cover much of the same ground.

[1] THE LANCET, Jan. 26th, 1901, p. 280.
[2] Brit. Med. Jour., vol. ii., 1891, pp. 1088, 1329.
[3] Churchill, 1858.
[4] THE LANCET, March 1st, 1890, p. 486.
[5] THE LANCET, March 18th, 1893, p. 629.

The first report (THE LANCET Chloroform report) based its conclusions upon (1) published records of deaths from 1847 to 1891 inclusive, a period of 44 years; and (2) answers to a circular letter inclosing forms for the guidance of correspondents engaged both in private and hospital practice. These were sent to all members of the medical profession in the United Kingdom and to leading surgeons abroad and in the colonies and the United States. The range of questions will be seen on reference to page 88 of the report. The British Medical Association report obtained its information from a very carefully drawn-up note-book which was sent to a number of hospitals, and contained, when returned to the committee, entries of all cases treated under anæsthetics in the hospitals during the year 1892-93. 136 of such report-books were returned with references to 25,920 cases. Although this report deals only with England and Scotland, and therefore does not correspond in scope with THE LANCET report, yet its figures and findings are sufficiently in harmony with the latter to render collation and comparison both simple and useful. We omit for the moment the appendices which deal *inter alia* with statistics of 1521 administrations of chloroform in India.

It strikes the student that the report is practically one dealing with chloroform and ether as administered in hospitals and by specialists in anæsthetics. The cases of nitrous oxide administration, although 2911 in number, present only slight departures from the normal in 25 cases and in only two of these instances called for remediable measures, and in none gave rise to anxiety. We cannot, however, admit that such figures can either prove the safety of, or indeed any noticeable facts about, an anæsthetic which must be used many thousands of times daily in the large towns of England alone. Forty-five anæsthetics, mixtures, and successions of anæsthetics are scheduled which besides nitrous oxide and that gas combined with oxygen (Nos. 28 and 29) represent (1) chloroform; (2) ether; (3) gas followed or mixed with the vapour of ether; (4) the A.C.E. mixture; (5) chloroform and ether in various proportions; and (6) successions of A.C.E., chloroform, and ether. The committee have further arranged the anæsthetics and mixtures into a chloroform group—i.e., those in which chloroform is the dominating factor—(1) chloroform; (4) A.C.E. mixture; (5) mixtures of chloroform and ether; (6) A.C.E. mixture followed by chloroform; (8) ether followed by chloroform; (14) chloroform followed by A.C.E. or a similar mixture—and an ether group, in which ether is the dominating constituent—viz., (2) ether; (3) gas followed by ether; (7) chloroform followed by ether; and (9) A.C.E. mixture followed by ether.

Two sets of environing circumstances possibly affecting the use of anæsthetics are considered, firstly, those such as age, sex, time of day and season of the year, the nature of the operation, with the antecedent condition of the patient; and, secondly, those which belong to the anæsthetic itself—e.g., whether ether or chloroform, or a mixture or succession was employed—the method adopted, the quantity used, and the duration of the administration.

With regard to sex and age, when all anæsthetics are considered together, the death-rate is unfavourable to males in the proportion of 20 to 9. This represents a death-rate of chloroform and ether and their mixtures and successions, the nitrous oxide group being omitted for reasons stated above. Women are less prone to danger under chloroform than are men (British Medical Association report) as 2 to 7 and to death as 1 to 3 (THE LANCET report, 8 to 23). Under ether the danger-rate is (British Medical Association report) as 4 to 3; the death-rate being equal. In must be noted in this connexion that three of the four ether deaths (Nos. 723 to 726) were in persons in an extremely precarious state, and, as the British Medical Association report shows later, in such cases the death-rate under chloroform and ether tends to equalise. In other words, the factor tending to danger in such deaths is the condition of the patient rather than the anæsthetic. In the other case the operation seems to have caused the death, as there were no signs of anæsthetic toxæmia. In THE LANCET report the deaths recorded under ether were as 5 to 6, being slightly more favourable to the females than the British Medical Association statistics. However, there is reason to believe that in THE LANCET report gas and ether cases were placed with those belonging to the ether group in all cases in which the dangerous symptoms actually occurred when the patient was under ether narcosis. If, therefore, we associate the British

Medical Association ether and ether and gas cases together we find a death-rate of three females to two males, while the danger-rate is as 3 to 2—a very striking comparison.

The age sections of the two reports are also of singular interest when placed side by side. In THE LANCET report dealing with chloroform, taking for the sake of comparison the first five years' deaths, in the male column as unity, we have the following table :—

—	Males.	Females.
From 1 to 5 years	1·0	0·28
„ 6 „ 10 „	2 71	0 71
„ 11 „ 15 „	2·14	0·85
„ 21 „ 25 „	3·7	2 14
„ 26 „ 30 „	3·14	0·85
„ 31 „ 35 „	2·42	1·14
„ 36 „ 40 „	2·42	1·0
„ 41 „ 45 „	4·57	1·57
„ 46 „ 50 „	4 57	1·28
„ 51 „ 55 „	1·95	0·42
„ 56 „ 60 „	3·42	1·0
„ 71 „ 75 „	0·29	0 1

This shows in the case of males an increased mortality-rate from one year to 25 years, then a decline to 35 years, and an increase to the maximum between 41 and 50 years. Between 51 and 55 years there is a marked fall. In females the maximum is reached between 21 and 25 years, the next highest rate occurring between 41 and 45 years, a period somewhat earlier than the male maximum. No tables giving death-rates as regards the sexes are given in the British Medical Association report as only 16 deaths due wholly to the anæsthetic are recorded, but the danger-rate which includes deaths and cases of grave danger is given below.

British Medical Association Report (Danger-rate) taken rate between One Year and Five Years as Unity.

Years.	Both Sexes.	Years.	Both Sexes.
From 5 to 15 years ...	2·06	From 41 to 50 years ...	1·12
„ 21 „ 30 „ ...	0·68	„ 51 „ 60 „ ...	0·62
„ 31 „ 40 „ ...	1 06		

The danger-rate between one year and five years is in the British Medical Association report extremely high, although the death-rate is 0·125 of the total.

Under ether the average age at death of males is 46 years (THE LANCET) and of females 40 years. Half of the male deaths took place between 45 and 55 years of age and most of the female deaths between 40 and 50 years. The percentage danger-rate (British Medical Association) for both sexes is highest between 50 and 60 years and next between 60 and 70 years. From 0 to 10 years it is *nil*, as it is also between 40 and 50 and after 70 years. However, it must be borne in mind that the danger-rate under gas and ether was highest between 20 and 30 years and that the deaths reported under these anæsthetics are only six, and of these, when the detailed reports are read, we find strong presumptive evidence against the anæsthetic *per se* having been the cause of death.

The conclusions on p. 72 (British Medical Association report) are noteworthy as they contradict the commonly stated fact that young children take chloroform almost with impunity. From one month to one year, from five years to 10, and after 30 years the percentage death- or danger-rate is above unity and below unity in the intermediate ages; the highest occurred between 70 and 80 years and the next between 40 and 50 years, which in the last period corresponds closely with THE LANCET report. The report adds: "It is remarkable that out of 36 administrations to children under one month there were three cases of danger."

The sections dealing with the effects produced by the season of the year and the hour of the day or night need not detain us. Unless special notes are made upon such subjects they escape the casual observer. Obviously the danger-rate as such depends upon other than diurnal or meteorological conditions. It is to be expected that dangers which arise in the night would under chloroform be due in many cases to the absence of an experienced chloroformist or other adventitious circumstances. It is, however, a matter of regret that there is no trustworthy information as to the incidence of such after-effects as bronchitis, pneumonia, shock, and collapse, during the warm and cold weather, and during the hours of maximum and minimum vitality.

The importance of the general condition of the patient at the time he has to take an anæsthetic is obvious, but it probably has less actual bearing upon either the danger- or death-rates of individual anæsthetics than would be suggested upon *a priori* grounds. In the first place, the patient whose condition is serious requires more care in the preliminary examination, and the choice of the anæsthetic is necessarily made with more judgment and after greater thought than can be expended in ordinary cases, as such persons are placed in the hands of the most experienced anæsthetist available and every precaution is taken. It is shown in the report before us that, whereas chloroform presents both a higher danger- and death-rate for the average man, woman, and child than do other anæsthetics, yet in proportion as the gravity of the physical condition of the patient increases, so, too, do the danger- and death-rates of various anæsthetics tend to become equalised. There are, however, special conditions which seem more dangerous when special anæsthetics are employed, and there are certain conditions which certainly increase the peril of taking any anæsthetic. In the three classes described in the British Medical Association report as "good," "not good," and "bad," complications under all anæsthetics taken together occurred least frequently in the first and most frequently in the second; while the danger-rate (including the deaths) was highest in the third and lowest in the first. For chloroform alone the same figures hold good, but in the case of ether, although the danger-rate agrees with the above, the difference between the second and third classes is less marked. Gas and ether follows the figures of all anæsthetics. When these three anæsthetics are compared we find that the "danger-rate" is slightly higher in the case of ether and six times higher in that of chloroform when compared with "gas and ether." A danger case was reported once in every 133 chloroform administrations, once in every 654 ether administrations, and once in every 834 "gas and ether" administrations when the persons taking the anæsthetic were in "good" condition. And this holds true in the "chloroform" and "ether" groups. This inequality between chloroform and ether is less marked in the second class and least in the third class—viz., 1·9 to 1·4 and 4·0 to 3·7 respectively.

When we pass to special diseases, or to the "pathological states," as they are termed in the British Medical Association report, we are again able to contrast the facts given with those furnished by THE LANCET report. Alcoholism was pointed out in THE LANCET report as one of the dangerous and frequent predisposing causes of accidents under chloroform, and in the details of the necropsies many of the lesions recorded are those found associated with chronic alcoholic poisoning. An inspection of the tables of deaths, pp. 104 to 164, where in column 8 the necropsies appear, reveals the large number of cases in which more or less evidence of alcoholism was shown among the fatal cases. This arrangement is also followed in the British Medical Association report on pp. 58 to 63. In this last-named report we find (p. 80) that alcoholism increased the danger-rate under all anæsthetics sixfold as well as increasing the complication-rate to nearly the same extent. Under chloroform the danger-rate was increased eight times. In the ether cases, although the complication-rate was triplicated, there was no instance of danger. Emphysema was pointed out in THE LANCET report to be, next to alcoholism, one of the most frequent predisposing causes of death, and the figures in the British Medical Association report agree except that they indicate this condition to be the most dangerous of all. Shock and collapse, affections of the heart, empyema, bronchitis, and anæmia are all mentioned as having been associated with a high danger-rate. It is also noticeable that when complications arose in the case of patients who suffered from any of these conditions they were usually associated with danger. Vomiting during anæsthesia is in both reports stated upon clear evidence to be commonly the cause of considerable danger. In the section (p. 103) dealing with "Phenomena of Anæsthesia" we find it stated: "The figures, indeed, are so striking as to suggest that the phenomenon" (i.e., vomiting and retching) "bears a causal relation to the onset of complications." There, however, seems to have been no special report offered as to the

dangers of anæsthetics in the case of persons who were vomiting as the result of disease before the administration of the anæsthetic. This point was investigated in THE LANCET report and the conclusion given was that such cases were peculiarly dangerous. It will be convenient, however, to defer more detailed examination of the matter to a later portion of this review.

When we come to the sections referring to operations we find more divergence between the reports under consideration than has hitherto revealed itself. In THE LANCET report the operations most attended with deaths are given in the order of danger for chloroform—extraction of teeth, reduction of dislocations, excision of joints, operations on bones, amputation of fingers, for fistula in ano, ablation of the eyeball, operations on the breast, and removal of the tongue. With the exception of the dental cases the operations named were mostly undertaken in hospital and the frequency of a fatal result really is a factitious one, as the figures bear a due proportion to the number of the operations of the nature actually performed. When viewed in this way the numbers only record what may be called the usual percentage of death-rate under chloroform for the operations in question. The British Medical Association report (p. 87), however, gives the following order of danger: major amputations and excisions, operations for ruptured perineum, excision of the eyeball, operations on the pleura and lung, abdominal sections and those upon the upper air-passages; circumcisions also showed an increased danger-rate. The absence of statistics concerning teeth extractions under chloroform is no doubt accounted for by the fact that at most hospitals gas is used for such cases, and it was chiefly from hospital statistics that the British Medical Association Committee compiled their report. Under ether the highest danger-rate was in the case of operations for strangulated hernia, and its extreme danger in such cases is borne out by collation of the two reports. It must be pointed out, however, that if the individual cases are studied it will be seen that in many instances the patients were *in extremis* at the time of the operation, and for this reason ether was the anæsthetic selected. Death seems in these cases to have arisen not from an overdose of ether but from the aspiration of stercoraceous vomit into the air-passages. We regret that we have not space to give the cases recorded of this condition in the two reports as they are very striking. The British Medical Association Committee are, however, inclined to regard chloroform as the safer anæsthetic in operations for strangulated hernia since there is a low danger-rate for this anæsthetic, most of the dangerous cases having been reported as occurring under ether. The evidence advanced, however, is not sufficient, we think, to prove this, however much the members of the committee as experts may, by reading into the report their personal experience, be inclined to the view cited above. In the two cases of death where ether was used, out of 34 cases of complication, one patient was *in extremis* and the other died two hours after the operation, and in both stercoraceous vomit was found post mortem in the air-passages. It is difficult to see why these cases were classed as deaths from ether, as probably both patients would have succumbed whatever anæsthetic had been administered (see p. 61, Cases 723, 724). The figures, we think, show that the probability is that an operation as such does not play a very important part in the mechanism of deaths under anæsthetics. In such heroic measures as must be adopted in some cases of abdominal sections, amputations and when a large quantity of blood is lost the anæsthetic may play a part in so far as it produces shock, promotes hæmorrhage, lowers the body temperature, or interferes with respiration or circulation. We should be inclined to say that on such occasions the important point was *how* the anæsthetic was given rather than what anæsthetic was chosen, that is, provided no special antecedent bodily condition of the patient demanded avoidance or selection of a special anæsthetic.

(To be concluded.)

PREVENTION OF CONSUMPTION.—Under the auspices of the Gloucestershire, Somerset, and Wilts Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis a public meeting was held at the town-hall, Bradford-on-Avon, on March 11th, under the presidency of Mr. John Fuller, M.P. An interesting address was given by Dr. Lionel A. Weatherly and a resolution in favour of the proposed sanatorium at Winsley was passed.

THE ROYAL COMMISSION ON SOUTH AFRICAN HOSPITALS.

(Continued from p. 888.)

VI.

SPEAKING generally, we quite agree with the remarks and recommendations of the Commissioners under the head of "Sanitation" and as to the appointment of sanitary officers for all towns and camps. As everybody knows, the lamentable experience obtained during the Crimean war was followed in Lord Herbert's time by energetic movement in the direction of army sanitation in both peace and war, and in the appointment during the latter of a duly qualified officer armed with the requisite power to act as a sanitary officer on field service. Such an appointment was always made until Lord Wolseley was presumably instrumental in abolishing it by declaring that a sanitary officer was practically useless on a campaign. We quite agree with the Commissioners, however, and with Sir William Thomson's and Dr. G. Turner's evidence (pages 358 and 395 minutes). There should be a sanitary officer-in-chief on every big military expedition possessed of large experience and high rank who should be charged with the general direction of sanitation of the army in the field and who should also be in the confidence of both the general commanding and the principal medical officer. Although it is quite true that principal medical officers of divisions and of army hospitals act as sanitary officers, and that medical officers generally are well instructed in army hygiene and should one and all be held responsible for any neglect in this respect within their respective spheres of duty, still it should certainly be the special duty of some one officer to have the general direction. He should, as far as possible, inspect, report, and advise as to everything appertaining to the sanitation of troops in the field. While everyone must recognise the great importance of army sanitation we are, nevertheless, bound to say that the conditions of war are altogether different from those of civil life. This is a point, however, which is not sufficiently realised by the public. Let the occurrences described by Dr. W. Johnson (9584, 9586, and 9588, Minutes) be taken in illustration of what happens in war. It is not so much the want of knowledge as the difficulty or impracticability of applying it in war that is the obstacle to be overcome.

We have no desire whatever to shelter ourselves behind platitudinous generalisations, but the matter has, unfortunately, to be looked at from a concrete and practical and not from an abstract point of view. We have only to turn to the war news of late and the forced marches in pursuit of the Boers, for example, to see how little chance there is for the application of practical hygiene. If a foe gave some intimation of his intended movements and did not begin his fighting until both sides were ready the matter would obviously be materially simplified, but it need scarcely be said that this is never the case. Time is a necessary element in carrying out even the simplest and best-devised sanitary arrangements. In the case of sieges, in permanent or temporary camps, and in the case of captured or occupied towns there is usually no excuse for neglect or carelessness; but even in such cases the practical application of elementary sanitary principles pre-supposes, not only the presence of competent advisers to point out what has to be done, but of a properly organised executive of sanitary engineers and workmen with all necessary appliances—down to carts, picks, and shovels—to do it. Camp conservancy and latrine systems, camp cleanliness generally, drainage, water-supply, disinfecting processes, a sanitary police system, and so forth, have all to be attended to, and very promptly, if they are to be efficacious in preventing or limiting the spread of disease. A sanitary department, with its directing heads and subordinate staff and a body of navvies, would prove an effective agency in time of war, but if not sufficiently trained to arms to fight and protect themselves in case of attack they would have to be protected by troops. Soldiers can fulfil both functions; only as a matter of fact the presence and aid of troops in carrying out sanitary work cannot always be had when needed or relied upon for various reasons. Again, where the movements of a force are rapid and changes of position are unexpected, and when troops have to fight, to

capture, and to occupy some position, they must for the moment take what they find there; and if there happen to be contaminated water and foul and infected soil mischief is soon done the results of which are bound to follow and unfold themselves with the regularity of clock-work. The necessary precautions are not, perhaps, or from the nature of the case cannot be, taken in time; indeed, to prove efficacious they would often need to have been taken in advance of the arrival of the troops. So that although it may be true that enteric fever is a "preventable" disease the term "preventable" is apt under such circumstances to be a very misleading one. Notwithstanding that it may be common knowledge that enteric fever is endemic in a country which is the seat of war, the knowledge is of little avail unless the time of its incidence with epidemic force and the locality are also known. The choice of sites for encamping troops is a matter of vital importance, and so is the periodical and frequent changing of camp sites. This latter is not sufficiently laid down in text-books on army hygiene, and it is difficult, perhaps, to formulate any precise rule generally applicable, but it is a really important point. Wherever any disease, and especially any epidemic disease, is prevalent, the rule should be to change the site as soon as possible. It is, of course, deplorable that such a case should occur as that of the 2nd Worcesters related by Mr. Burdett-Coutts (page 47 of "The Sick and Wounded"), and the troops should also be safeguarded, as far as possible, against such evils as those described by Dr. G Turner in his evidence already referred to. It is needless to add that we fully concur in Dr. Turner's recommendations.

We now proceed to Part III. of the Commissioners' report dealing in detail with the care of the sick and wounded in various places during the campaign in South Africa. This section comprises the pursuit of General Cronje and the surrender of his force at Paardeberg, the occupying of Bloemfontein, and the advance of the British forces to Pretoria, the capital of the Transvaal. We are not going to describe the dramatic course of events comprised in this most successful portion of the campaign, following so closely upon the dark and gloomy occurrences which had preceded it. From a military standpoint it was a glorious but terribly trying time for the troops.

In this portion of the report the Commissioners have to deal with the most difficult and controversial part of their inquiry, for it includes that period of the medical history of the war about which public feeling was most deeply stirred. On the publication of Mr. Burdett-Coutts's letter in the *Times* of June 27th, 1900, it was only to be expected that anxious inquiries would be made on all sides as to the truth or otherwise of the allegations set forth with so much realistic detail and suggestiveness. The real gravamen of that letter, as we said at the time, lay not so much in the statement that deplorable scenes and occurrences had taken place as in the deliberate statement that they arose from causes which might have been foreseen and prevented. The letter appeared, too, at a time when all in this country were full of gratitude and admiration for the noble work which had been done by the medical service in the field and when there was so much in other directions to cause grief on account of the losses that had been sustained and to give rise to dismal forebodings in the faint-hearted. For let it be borne in mind that the medical service, according to the testimony of all, expert and otherwise, except those crude and carping critics who are always lynx-eyed to discover defects and colour-blind to all else, had done its work most successfully. Up to, and even after, the time that Sir William Mac Cormac and Mr. Treves left South Africa the medical arrangements were excellent—they had never been better, if so good. If we may say so without impertinence to these gentlemen, their reports gave an absolutely truthful record of what had been and was being done. The most serious strain was, however, still to come. The army of the Natal command had fought its battles and suffered severe losses, but its health was fairly good. It was fighting on healthy soil and contiguous to a railway, and if it had but a relatively scant amount of wheeled and other transport it still had a sufficient amount to meet all its urgent requirements. Up to a certain point it had, too, a large and devoted as well as most efficient body of Indian dhoolie-bearers at its service The same may be said generally of Lord Roberts's force up to the time it reached the Modder. Then came the march to Kimberley, the surrender of Cronje, the occupation of Paardeberg, with the fouled river Modder and the offensive laager, the subsequent occurrence of enteric fever, the march to Bloemfontein, and the capture of the waterworks by the Boers on April 3rd, 1900, with a renewed infection of the troops the results of which were to manifest themselves in due season and in chronological sequence. The army after leaving Kimberley, being diverted from its direct course by the Cronje episode, had soon to relinquish the use of the stationary hospitals and railway to its rear. The line of communications behind Lord Roberts's advance became cut and interrupted by the enemy, and he was soon to find himself and his force in a very analogous position to that of the army of General Sherman when that general made his celebrated march and thereby helped so materially to bring the great American war to an end.

It is well to epitomise the facts because in any attempted examination, analysis, and consideration of the report with its accompanying minutes of evidence and appendices, together with the publications which have preceded and followed these, the reader will soon find himself in a maze of entanglement with little or no clue to guide him and amidst plenty of pitfalls for the footsteps of the unwary. If at one moment he thinks that he has some firm foothold of fact as stated at one place he will find that this is somewhere else contradicted or susceptible of some easy explanation which robs it of its significance. After much labour perhaps in following out what seems to be here and there a clue he will give it up because of its being found on examination to be based on illusory, sensational, or insufficiently precise evidence. To take an illustrative example, let the reader turn to Mr. Murray Guthrie's evidence at page 67 of the minutes of evidence and compare it with that of Superintendent Nursing Sister Holland (page 267 *et seq.*), with that of Surgeon-General Wilson (10,894, 10,896, 11,009, 11,026), with that of Lieutenant-Colonel W. L. Gubbins (pages 387 *et seq.* of Minutes), and with pages 42–43 of the Commissioners' report. We feel bound to say that the Commissioners appear to have spared neither labour nor pains in trying to investigate all the charges that have been brought against the hospitals in South Africa. They have shown, at any rate, that several of them were not proved, or were exaggerated if not altogether groundless.

The emphasis which we have laid in THE LANCET on transport as one of the prime factors in warfare is fully justified. Transport is a word which crops up everywhere in the pages of the report. A fatigued and half-starved army of exhausted men and horses arrived at Bloemfontein on March 13th, 1900, where, to add to the evils, the waterworks were, as we have said, captured by the enemy and the force found itself dependent for its supplies of food, forage, and ammunition on a single and precarious line of railway. Enteric fever, the seeds of which were apparently first sown at the Modder river, was already prevalent in the British force as it had been among the Boers at Paardeberg, and culminated in a sudden and widespread epidemic. That was the position. Mr. Burdett-Coutts thought that if the trucks of one day's trains had been devoted to the transport of hospital supplies during the stay of the troops at Bloemfontein the situation would have been saved (page 64, "The Sick and Wounded in South Africa"). He seems to have been reticent in those quarters where his representations would have been likely to be effective and not quite able to view the situation as a whole. An army must have food and ammunition and transport to supply them, or the safety of the whole force, healthy as well as sick, will be jeopardised. Lord Roberts's army was, for the time being, cut off—"in the air," as it is said—and supplies had to be obtained in the first instance to meet immediate necessities and in the next to ensure a fresh movement. No one seeks to shelter himself from adverse criticism under cover of Lord Roberts's authority, but had the forced marches and the unforeseen and unexpected movements of his army not taken place there would have been more transport by rail and otherwise at command, more time to make arrangements for getting up and opening out and equipping hospitals, and sacrifices of suffering and life need not have taken place. But in that case the army might not have arrived at Bloemfontein, and subsequently at Pretoria, when it did. If the reader turns to the military despatches of Lord Roberts—which were written without any reference to the medical service—published in the *London Gazette* of Feb. 8th last he will find a strong sidelight reflected on the extreme difficulties of the position, more especially in regard to transport. The exhaustion of troops and horses, the difficulties as to feeding the force, the destruction of the bridges over the Orange river are all described. In his

eighth despatch he dwells on the magnitude of the task that Her Majesty's troops had to perform where the area included in the theatre of war covered 458,030 square miles, while the distance which the troops had to travel by land was proportionately enormous. Regarded from such a point of view the responsibility was that of the Field Marshal and his staff, and, what is more, they were, as it seems to us, fully justified under the circumstances in incurring it. It was no doubt Lord Roberts's recognition of this fact and of the soundness and strength of the reasons which impelled him to act as he did that led him to ask for a small body of common-sense business-like men to be sent out to investigate the circumstances. For our part we almost wonder, if he were fully satisfied, as he emphatically said he was, with the efforts made by the medical officers, that he did not at once assume the whole responsibility of the situation. We do not say that there were no shortcomings, no serious defects or errors of administration, no wasted and misapplied energy on the part of the medical service. The report proves that there were. But it is so easy to be wise after the event. The provision of a general hospital at Orange river would have been of great service, for instance, could the movements have been foreseen.

We are not impugning Mr. Burdett-Coutts's motives. He seems to have acted under an imperative sense of public duty. Still, as we have said, the course that he took does not commend itself to our mind. It seems to us that in view of the great and widespread pain and sorrow that would inevitably follow the publication of his letter recourse should not have been had to that measure until remedy seemed to him hopeless in any other way. Every effort might first have been made to help those directly and officially concerned to set aright what had gone wrong. No one has a right to consider that he monopolises the feelings of pity and of humanity. But having arrived at the conclusion that as a matter of humanity it was his bounden duty to write to the public press it seems to us that he might have protested as emphatically as he liked against what he considered to be wrong without entering into all the harrowing details he did. Moreover, if our readers will turn to Lord Kitchener's evidence (13,354–55–56), Lord Stanley's evidence (12,741), and Surgeon-General Wilson's evidence (pages 320 and 321, paragraphs 11,004 to 11,009) they will see that Mr. Burdett-Coutts did not always take advantage of his opportunities for representing matters in the proper quarters, while his warmth of advocacy in the House of Commons of the cause which he had taken up led him into a somewhat grievous inaccuracy of statement. Surgeon-General Wilson says: "I see that Mr. Burdett-Coutts in the House of Commons mentioned my name personally, and he said he told me of the condition of things at Bloemfontein over and over again. I see in his evidence before you, my lord, he admitted he did not. I can fill up the rest of it by saying he absolutely never did mention anything to me over and over again; he never mentioned it once." What is more, Surgeon-General Wilson adds that, although he saw Mr. Burdett-Coutts constantly, he never made any complaint to him.

We did not hesitate from the first to admit the substratum of fact in the picture which Mr. Burdett-Coutts drew in his letter to the *Times*. Stripped of its word-painting there was at least sufficient evidence to show that at one time the accommodation for the sick and wounded at Bloemfontein was quite inadequate to the occasion, that hospitals were terribly overcrowded and badly provided, that there was a state of stress and strain, and that a good deal of suffering attributable to these and other causes was entailed upon a large and rapidly augmenting number of sick mainly owing to a very severe outbreak of enteric fever on a scale the dimensions of which had not been foreseen. We think it must be admitted that his allegations in these respects, after setting aside all disproved, unproved, or exaggerated statements and embellishments, have been corroborated. The picture presented to us by Mr. Burdett-Coutts is that of a deplorably bad condition of the sufferers from enteric fever closely packed together and without some of the most elementary necessaries. He rightly complains of the want of medical attendance and nurses. Under such conditions as these, however, it seems superfluous to inquire whether there was any want of medical men, nurses, and orderlies. If any number of these could have been "wafted" from England or elsewhere to the spot they would only at the moment have been a source of embarrassment instead of help to the whole force, for they must themselves have been fed and lodged somewhere and somehow to have been of any use to the sick. Mr. Burdett-Coutts disclaims the intention of making any reflection upon the *personnel* of the Royal Army Medical Corps. He may even have eulogised their work, but the whole tenour of what he has said and written seems to us to be to exalt the work performed in the hospitals maintained by private bounty at the expense of the military institutions and their medical staff. He is entitled, of course, to hold and to express any opinion that he likes, but he cannot blow hot and cold at the same time, nor is he fairly entitled to draw calumnious generalisations from isolated instances.

THE BARBERS' COMPANY.

PRESENTATION OF THE HON. FREEDOM TO THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ON Tuesday last Sir W. Mac Cormac, Bart., K.C.V.O., President of the Royal College of Surgeons of England, was presented at Barbers' Hall with the Hon. Freedom of the Barbers' Company. Speaking at the banquet which followed the proceedings Sir W. MAC CORMAC said:—

I should, Mr. Master and Wardens, first like to express to you and to this venerable company my sincere appreciation of the distinction conferred upon me to-day of its honorary freedom and the pleasure it has afforded me to receive it. The Guild of Barbers is of such ancient foundation that its earliest records can no longer be traced. It may, at all events, be assigned an origin as early as the thirteenth century, and before its final development into a trade guild it was partly religious in character and partly social. The barbers used to assist the monks to perform operations, but after the edict of Tours in 1163 forbade the priests to shed blood it is probable that the barbers assumed a much larger share of surgical work and performed all the minor operations, and in those days there were few besides.

In 1462, the first year of the reign of King Edward IV., the Barbers obtained a charter of incorporation and became a City Company, "the better to protect the King's lieges from going the way of all flesh through the ignorance and negligence of various unskilful Barbers and other practitioners in surgery." In 1530 the Company drew up ordinances for the better government of its members, a document of much historic interest, as it is signed by Sir Thomas More, then Lord Chancellor of England. There was also from remote time a "Surgeons' Guild," small in number, poor, called a "Fraternity" and chiefly consisting of military surgeons. The surgeons became merged in the Barbers' Company in 1540 and remained members of a united company for 200 years until they finally separated in 1745 and were constituted a Company of Surgeons, a movement attended by many quarrels. From this body was evolved the present Royal College of Surgeons of England which became incorporated on March 22nd, 1800, and, as many of you know, the Royal College celebrated the centenary of its foundation last year. It is interesting to find that in France very similar conditions obtained. There were in Paris during the fourteenth, fifteenth, and sixteenth centuries three kinds of medical practitioners—a corporation of physicians, a confraternity of surgeons founded in the thirteenth century, and a company of barber-surgeons—and these three bodies were engaged in almost perpetual strife for their respective privileges. About the year 1400 it is said that there were in Paris 31 physicians of the faculty, 10 master surgeons of the fraternity of Surgeons, and about 50 barber-surgeons. The barbers continued separate until 1505 when they became barber-surgeons and formed a numerous and powerful body, especially a little earlier when Ollivier le Dain was barber-surgeon to Louis XI. and had the ear of the king.

Ambroise Paré, who was surgeon in succession to five French monarchs—Henri II., Francis II., Charles IX., Henri III., and Henri of Navarre—was a barber-surgeon from 1541 to 1544, and took a prominent part in these quarrels; afterwards he was admitted to the fraternity of St. Come, which consisted of the Master Surgeons, closely corresponding to our Company of Surgeons. It is interesting to note that Paré when he was 65 years old dedicated his great surgery to the king, and he there tells us that "he had laboured 40 years to bring his art

to perfection and striven so hard to attain his end that the ancients have nought wherein to excel us, and posterity will not be able to surpass us." It is extraordinary that this boast of attained perfection made more than 300 years ago had remained largely true until the latter half of the nineteenth century witnessed the transformation of surgery. This assertion of perfection has been made with curious frequency by surgeons. The celebrated French surgeon, Baron Boyer, who was also at one time a barber-surgeon, says in the preface to his great work on Surgery published in 1814 that surgery had made the greatest progress and had arrived at the highest degree of perfection of which it was susceptible. Sir John Erichsen and others have in their time said much the same thing.

In 1655 the French Master Surgeons petitioned to be allowed to join the Company of Barber-Surgeons—about 100 years later than their English *confrères* who became a united company in 1540, and they so continued till 1745, when they separated in the same year that witnessed the dissociation of the surgeons and barbers in England. The quarrels between the barbers and surgeons are now ancient history; any ill-feeling has long since disappeared, and I think I may assume that the honorary freedom which you have bestowed upon me symbolises a friendly reunion. There is no doubt that the election to-day of the President of the Royal College of Surgeons of England to the honorary freedom of the Barbers' Company constitutes the first official link between the two societies since their separation more than 150 years ago, and one must go still further back to a period antecedent to 1540, when the barbers and surgeons were still separate bodies, for the possible occurrence of a member of the old fraternity of surgeons being elected a freeman or an honorary freeman of the Guild of Barbers. There is a record of a surgeon, one Master Johēs de Suthwerk (John of Southwark), being given the ordinary freedom of the Guild of Barbers in 1312 in the fifth year of the reign of King Edward II., a body amongst whom there were practitioners of surgery, but no honorary freedom has been conferred upon any one since the separation in 1745, nor, indeed, since 1663. In that year James, Duke of Monmouth, a natural son of Charles II., Alexander Lord Leven, Richard Hopton, and Thomas Rosse, Esquires, received the honorary freedom, but apparently no surgeons. The only other honorary freemen were Henry Nevill Lord Bergavenny in 1584 and Thomas Lord Windsor in 1631.

Your history can point to many famous surgeons, no fewer than 19 of them having been serjeant-surgeons to the king or queen. William Hobbes, a member of the Company, appears to have been appointed the first serjeant-surgeon in 1461. Thomas Vicary, born between 1490 and 1500, whose portrait we see in the first kneeling figure on the king's left hand in Holbein's picture, was granted the office in 1530. Richard Ferris, a very notable man, was appointed serjeant-surgeon to Queen Elizabeth in 1562 and afterwards to Edward VI. He tried to make surgery a profession and thought surgeons should know physic. Thomas Gale, surgeon to Elizabeth, born in 1507, was twice Master of the Barber Surgeons. He served in the army of Henry VIII. and was present with Philip II. of Spain at the battle of St. Quentin in 1557. He was a contemporary of Ambroise Paré who was also present at this battle, where he occupied himself in repairing the damage done by the English soldiers. William Clowes the elder, born in 1540, was surgeon to Queen Elizabeth and served against the Spanish Armada in 1588. He was a warden of this Company and a surgeon to St. Bartholomew's Hospital. He saw active service during many years both in the army and the navy. His published works are written in vigorous English and are the best surgical treatises of the Elizabethan time. He was very outspoken, and this got him into trouble, as is more than once recorded in the annals of the Company. On one occasion the strife of words between George Baker and William Clowes ended, we are told, in a "fight in the fields." Baker afterwards became serjeant-surgeon to Queen Elizabeth and was Master of the Company in 1597. William Clowes the younger was serjeant-surgeon to Charles I. He was not quite so great a man as his father. In 1625 we find a long letter from him asserting his rights in the Company and declining to act as renter warden since he "must not so poorly value the King his Master but expect from the Company as good a respect as any Serjeant Surgeon heretofore." Halle, Banester, and Reid were well-known Elizabethan surgeons, and Woodall and Wiseman followed them during the Stuart period and the Commonwealth. All were men who had seen much service in the wars and occupied very high places in their profession. Their biography can scarcely be told now, but much of interest is related of them, and they helped in their day to raise the dignity and importance of their calling and the prestige of the Company.

Your records abound in matters of interest which Mr. Sidney Young, your most able historian, has compiled with loving care. In the archives preserved at Guildhall the barbers are admonished not to advertise improperly, and not to expose blood in their windows, but to have it privately carried to the Thames. The barbers rightly claim to have been the first of the city companies to give technical instruction in their craft by anatomical lectures and demonstrations. The attendance on these lectures was compulsory and they were for long given in the theatre built by Inigo Jones and depicted in one of Hogarth's telling pictures. The subject matter was found in the bodies of persons executed at Tyburn or elsewhere, the company having the right to claim four in each year. Upon the beadles devolved the unpleasant and sometimes dangerous task of bringing the dead bodies to the hall. There was generally an ample material to choose from, and when the selection had been made the body was placed in a coach and carried off. Not infrequently the hangman, who had vested interests of his own, or the relatives of the persons executed, or the mob, protested with violence, maltreated the beadles, and rescued the body. In the annals for 1555 it may be seen that the doctor appointed for the "anathomye" was provided with a mat to guard against cold in the feet, two fine white rods with which to touch the body, and a wax candle to look into it; also an apron and sleeves both white and clean. Nevertheless, in 1631 it is recorded that great annoyance was caused to the dresser-boards and utensils in the upper kitchen by reason of the blood, filth, and entrails of the "anathomies," and another room was built in order to preserve the kitchen to its proper use. I believe we sit at our banquet to-night around the old dissecting-room table.

Two apparently authentic instances are mentioned in the records of the resuscitation of executed criminals. One was on Feb. 20th, 1567, "when a strange thing happened to a man hanged for felony at St. Thomas Wateringe. The surgeons begged to have him for an anathomye. He was stripped, hid in a chest, thrown in a carre, and so brought from Southwark over the bridge to Chirurgeons' Hall near Cripplegate. The chest being opened, the weather extreme cold, he was found to be alive and lived to the 23rd of February." The other instance was that of William Duell, a youth of 16, who was hanged at Tyburn on Nov. 23rd, 1740, "where, having hung for some time, he was cutt down and brought to the Company's Hall for dissection. He had not been there five minutes before life appeared in him, and in less than two hours he sat up and drank some warm wine." He was conveyed back to Newgate where he recovered completely and was afterwards transported for life.

In the sixteenth and seventeenth centuries the physicians and also the bishops challenged the privileges of the Company, but in the end without much success. The Company maintained their rights and haled offenders before them. In 1616 an amusing account is given of the behaviour of a John Walgrave before the court. He said he had "the authority the Archbishop of Canterbury and Bishop of London to practise, and was an antienter Surgeon than anie of them." He defied the court and made many untimely and irreverent speeches. About 1684 the surgeons in the Company began to seek for separation, the barbers protested against the undue influence exercised by the surgeons, and the matter was referred to the law. The feud continued, and the final separation took place in 1745.

I would say, in conclusion, that the Master and Wardens of this Company were good enough to lend some of their ancient and valuable plate to the Royal College of Surgeons of England on the occasion of the centenary. It was a graceful act on their part which was much appreciated by the College, and perhaps this incident may have suggested to your Master the compliment he has with so much good spirit and good taste bestowed on me to-night. Old associations, like old books, old friends, and old wines, are oftentimes of the best, and it was a happy thought of your Master to revive them. Master, Wardens, and Members of this ancient Company, I tender to you once again my cordial thanks and grateful appreciation.

In replying to the toast of "The Bench and the Bar"

Sir Edward Clarke, while in no way modifying his previous utterances, declared himself to be now at one with the Government in their South African policy, the Boers having rejected fair and generous terms.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE ADDRESS TO THE KING.

THE following is the text of the address of loyalty and condolence presented on March 20th by the Royal College of Physicians of London to His Majesty the King:—

"*To His Most Excellent Majesty, Edward, by the Grace of God of Great Britain and Ireland King, Defender of the Faith, Emperor of India.*

"The humble address of the Royal College of Physicians of London.

"May it please your Majesty:

"We, your Majesty's dutiful and loyal subjects, the President and Fellows of the Royal College of Physicians of London, humbly approach your Majesty, assuring your Majesty how deeply we share in the profound sorrow which has overshadowed every part of your dominions, through the death of our revered sovereign Lady Queen Victoria, and praying to be allowed to offer your Majesty, your Royal Consort, and all the Members of your Family our heartfelt sympathy in this your sad bereavement.

"We commemorate, gratefully and reverently, the lofty character of our late Sovereign, the virtues which distinguished her life in all its relations, public and private; her self-sacrificing devotion to duty and to all that might promote the welfare of her subjects, and her large-hearted sympathies which won her, in an unexampled degree, the love of her people.

"But while we lament the irreparable loss which the nation has sustained we are deeply sensible of the good Providence of God which has preserved your Majesty, through many years and many perils, to ascend the throne of your illustrious ancestors, with a knowledge and experience of public affairs and of all classes of your subjects which cannot but prove of signal advantage to the State. We cannot forget the round of public service, rarely intermitted, which your Majesty while Heir Apparent rendered to your people; and, as more particularly touching ourselves, we recall your Majesty's devotion to the cause of the sick and disabled poor in this vast metropolis, and the invaluable aid which your Majesty has given at a very critical period to those truly Charitable Institutions, the Hospitals of London, with which our Profession is so closely associated. We also recall with peculiar gratification the recognition which your Majesty has given to the Profession of Physic, and to its honourable and beneficent character, by allowing your name, while Prince of Wales, to be enrolled as an Honorary Fellow of our College.

"Lastly, we pray your Majesty to accept the assurance of our unswerving loyalty and deep devotion to your throne and Person, and we earnestly pray the Almighty to sustain you in your present trial, and long to preserve your Majesty to reign over a loyal people and a united empire.

"Signed.

"W. S. CHURCH (President).

(College seal.) "EDWARD LIVEING (Registrar).

"From our College in London,

"January 31st, 1901."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6324 births and 4162 deaths were registered during the week ending March 23rd. The annual rate of mortality in these towns, which had been 21·5 19·6, and 18·9 per 1000 in the three preceding weeks, further declined last week to 18·4. In London the death-rate was 17·8 per 1000, while it averaged 18·8 in the 32 large provincial towns. The lowest death-rates in these towns were 10·7 in Halifax, 11·4 in West Ham, 12·1 in Wolverhampton, 12·9 in Brighton, and 13·0 in Oldham; the highest rates were 22·7 in Huddersfield, 23·0 in Preston, 23·4 in Manchester, and 23·6 in Liverpool. The 4162 deaths in these towns included 356 which were referred to the principal zymotic diseases, against 395, 376, and 370 in the three preceding weeks; of these 122 resulted from whooping-cough, 93 from measles, 53 from diphtheria, 38 from diarrhœal diseases, 27 from scarlet fever, 22 from "fever" (principally enteric), and one from small-pox. No death from any of these diseases occurred last week either in Croydon or in Halifax; in the other towns they caused the lowest death-rates in Wolverhampton, Oldham, and Huddersfield; and the highest rates in Bristol, Liverpool, Hull, Sunderland, and Gateshead. The greatest proportional mortality from measles was registered in Liverpool, Bolton, and Hull, from scarlet fever in Sunderland, from whooping-cough in Bristol, Cardiff, Swansea, Birkenhead, Hull, and Gateshead, and from diarrhœal diseases in Burnley. The 53 deaths from diphtheria included 14 in London, five in Sheffield, three in Bristol three in Leicester, and three in Blackburn. One fatal case of small-pox was registered last week in Cardiff, but not one in any other of the 33 large towns; and no small-pox patient remained under treatment in any of the Metropolitan Asylums hospitals on Saturday last, March 23rd. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1598, against numbers decreasing from 2535 to 1652 on the 12 preceding Saturdays; 151 new cases were admitted during the week, against 185, 140, and 130 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 501, 463, and 394 in the three preceding weeks, further declined last week to 332, and were 152 below the corrected average. Influenza was certified as the primary cause of 30 deaths in London last week, as compared with 35, 39, and 30 in the three preceding weeks. The causes of 53, or 1·3 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bolton, Leeds, and in 11 other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Liverpool, Blackburn, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·5, 23 4, and 22·7 per 1000 in the three preceding weeks, further declined to 21·1 per 1000 during the week ending March 23rd, but showed an excess of 2·7 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13·4 in Perth and 15·5 in Greenock to 22·4 in Dundee and 23·4 in Glasgow. The 663 deaths in these towns included 38 which were referred to whooping-cough, 15 to diarrhœa, 11 to small-pox, eight to measles, seven to diphtheria, six to "fever," and two to scarlet fever. In all, 87 deaths resulted from these principal zymotic diseases, against 122, 113, and 98 in the three preceding weeks. These 87 deaths were equal to an annual rate of 2·8 per 1000, which was 1·2 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 67, 51, and 40 in the three preceding weeks, further declined last week to 38, of which 18 occurred in Glasgow, eight in Dundee, six in Edinburgh, three in Leith, and three in Paisley. The deaths from diarrhœa, which had been 23, 15, and six in the three preceding weeks, rose again to 15 last week, and included five in Glasgow, four in Dundee, three in Aberdeen, and two in Edinburgh. The deaths from smallpox, which had been 12 20, and 24 in the three preceding weeks, declined again to 11 last week, and were all registered in Glasgow. The deaths from measles, which had been 15 and 10 in the two preceding weeks, further declined last week to eight, of which five occurred in Edinburgh. The seven fatal cases of diphtheria corresponded with the number in the preceding week, and included three in Glasgow and three in Edinburgh. The deaths from different forms of "fever," which had been six in each of the two preceding weeks, were again six last week, of which three occurred in Glasgow and three in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 161 and 171 in the two preceding weeks, declined again last week to 126, and were 44 below the number in the corresponding period of last year. The causes of 30, or nearly 5 per cent.,

of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 46·6, 39·6, and 34·6 per 1000 in the three preceding weeks, rose again to 36·6 during the week ending March 23rd. During the past four weeks the death-rate in the city has averaged 39·4 per 1000, the rate during the same period being 18·9 in London and 22·8 in Edinburgh. The 243 deaths belonging to Dublin registered during the week under notice were 13 in excess of the number in the preceding week and included 15 which were referred to the principal zymotic diseases, against 12 and 14 in the two preceding weeks; of these, seven resulted from whooping-cough, five from diarrhœa, two from "fever," and one from diphtheria. These 15 deaths were equal to an annual rate of 2·2 per 1000, the zymotic death-rate during the same period being 1·6 in London and 3·2 in Edinburgh. The fatal cases of whooping-cough, which had been five, 10, and 11 in the three preceding weeks, declined again last week to seven. The five deaths from diarrhœa exceeded the number recorded in any previous week of this year. The 243 deaths in Dublin last week included 50 of children under one year of age and 70 of persons aged upwards of 60 years; the deaths of infants exceeded the number in the preceding week, while those of elderly persons showed a decline. 10 inquest cases and six deaths from violence were registered; and 85, or more than one-third, of the deaths occurred in public institutions. The causes of 17, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons T. Austen to the *Talbot* and E. R. D. Fasken to Plymouth Hospital. Surgeons: J. A. Forrest to the *Talbot;* L. Lindop to the *Howe;* W. Keith to the *Vernon;* F. J. McKenna to the *Plover;* J. H. Lightfoot to the *Lion;* and J. St. J. Murphy to the *Britannia*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant B. B. Burke has embarked for service in India.

Lieutenant-Colonel P. H. Johnston is granted the local rank of Colonel whilst in charge of a general hospital in South Africa. Lieutenant-Colonel A. T. Sloggett is granted the local rank of Colonel in South Africa whilst in charge of an Imperial Yeomanry hospital. Surgeon-Major C. R. Kilkelly, Grenadier Guards, is granted the local rank of Lieutenant-Colonel in South Africa whilst in charge of an Imperial Yeomanry hospital.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major J. W. Cook, having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers.

INDIA AND THE INDIAN MEDICAL SERVICES.

The King has approved of the retirement of the undermentioned officers:—Lieutenant-Colonel George Michael James Giles, Bengal Establishment, and Major Edward Ronald Da Costa, Madras Establishment.

VOLUNTEER CORPS.

Rifle: 3rd Volunteer Battalion the Cheshire Regiment: Thomas Andrew Rothwell to be Surgeon-Lieutenant. 3rd Volunteer Battalion the South Wales Borderers: Lieutenant Edward Meredith Griffith resigns his commission and is appointed Surgeon-Lieutenant. 2nd Volunteer Battalion the Loyal North Lancashire Regiment: Surgeon-Major E. M. Garstang to be Surgeon-Lieutenant-Colonel. 5th (West) Middlesex: Surgeon-Lieutenant J. N. Brown to be Surgeon-Captain.

SOUTH AFRICAN WAR NOTES.

Captain P. J. Probyn, R.A.M.C., and Civil Surgeons T. B. M. Sherwen, A. McMunn, J. Davidson, H. Baylis, A. W. J. McFadden, L. H. G. Stephens, and A. B. Tucker have been discharged from hospital to duty.

Lieutenant A. C. Lupton, R.A.M.C., and Civil Surgeon A. Granville, has arrived in England.

ANTI-TYPHOID INOCULATION.

The March number of the *Scottish Medical and Surgical Journal* contains an article, entitled, "The Edinburgh Hospital in South Africa and its Work," by Dr. Francis D. Boyd of Edinburgh, physician to the hospital. Somewhat over 150 cases of enteric fever were admitted, the mortality of those which were under treatment during the whole of the attack being 10·7 per cent. His opinion with regard to protective inoculation is that its effects on the mortality of the disease can only be deduced from statistics dealing with very large numbers, and he has seen at least one case where inoculation markedly lowered the health standard of the individual. The statistical part of his reference to the subject is as follows:—

Of the staff of the Edinburgh Hospital 58 were inoculated, 27 being done once and 31 twice. In seven the inoculation appeared to produce no appreciable effect. In a smaller number there was merely a slight local reaction as indicated by some tenderness at the point of inoculation perceptible on the following day. In the very large majority of cases there was marked local and general reaction. The effects of this inoculation were manifest in from two to five hours. There was a feeling of malaise and faintness, with, as a rule, a rise of temperature of 2° to 4°. In some cases there was an actual rigor. At the point of inoculation there was marked pain and swelling. The feverish condition lasted, as a rule, for 24 to 36 hours, after which the local swelling diminished. In some cases there was marked enlargement of the lymphatic glands nearest to the point of inoculation which persisted in one case for weeks. In the cases where inoculation was performed twice the second reaction was not so severe as the first. Amongst the staff of the hospital, of the 58 inoculated nine developed enteric fever. Of those nine cases one proved fatal, death supervening on the twenty-fifth day from a sudden attack of cardiac failure. It must in fairness be noted that the patient started his attack with an impaired heart from an old-standing mitral lesion. Of the remaining eight cases three may be described as very severe attacks with persistent high fever, and marked abdominal or nervous symptoms. In four cases the attack was pronounced, in one it was of an apyrexial type. ..... Of the soldiers admitted into hospital who had been inoculated inoculation had been performed once in every case. 18 cases of enteric were observed. Two were very severe, five severe, and 10 were apparently modified attacks. Though the signs and symptoms of enteric fever were present they were very mild, the fever not being high and often of short duration (seven to 10 days). In two complications occurred, five cases were admitted with a history of a slight fever with gastro-intestinal disturbance. It is impossible to be certain if these were cases of enteric fever. They may have been modified attacks, but some of the signs and symptoms were absent; and as they had been inoculated the presence of a positive Widal's reaction was valueless from a diagnostic point of view. Our experience thus has been that while inoculation appears to modify the disease, completely modified attacks are met with in the uninoculated. Again, very severe attacks with complications and relapse occur in those who have been inoculated. One cannot from this conclude that inoculation has been valueless, for had not the patient been inoculated the attack might have been still more severe.

AFFAIRS IN SOUTH AFRICA.

From a military point of view things are progressing favourably in South Africa, and we may now venture to believe that there are signs of the still further breaking up of the already disorganised Boer forces. General Delarey has suffered a bad defeat and lost a large amount of stores and ammunition in addition to a number of guns, horses, cattle, &c. General French, with Dartnell's and Pulteney's columns, has arrived at Vryheid after having killed, wounded, and captured 1200 Boers and taken seven guns and many rifles, and a vast number of horses, wagons, cattle, and sheep. Where General de Wet really is seems uncertain, but the belief is that he is attempting to join forces with General Botha. Politically we may say that the rejection by the Boers of the very generous and conciliatory terms proffered to them by this country has only served to bind more strongly together and to increase the number of those who trust that everything possible will be done to bring this war to a complete and speedy termination. Even the continental powers have come to recognise the fairness and generosity of this country in the terms which it has put forward but which Botha and his people have rejected. As regards the medical aspect of affairs in South Africa, the plague continues to make some progress and to be a source of trouble and embarrassment at Cape Town, its victims not being confined to the native population. Much difficulty arises from the concealment of cases of the disease. The Malay community in Cape Town are a source of obstruction to the local health authorities in carrying out their sanitary measures and policy. According to a telegram from Governor Sir W. F. Hely-Hutchinson to the Colonial Office the plague report for the week ending March 23rd was as follows: Cases admitted, 46; deaths, 21; suspects, 3; "contacts," 394. Some of the troopships conveying reinforcements are proceeding to Durban and other ports instead of to Cape Town. Recruiting for the theatre of war is proceeding in this country with great activity and large batches of men are embarking every week for the Cape. The sick-list and the list of deaths from disease in South Africa are not by any

means, we are glad to say, so lengthy as they were, but there is still a good deal of enteric fever and dysentery.

THE VOLUNTEER MEDICAL STAFF CORPS.

On March 23rd the prizes of the London companies of the Volunteer Medical Staff Corps were presented at the headquarters in Calthorpe-street by Mrs. Squire, wife of the commandant, Surgeon-Lieutenant-Colonel J. E. Squire. The challenge shield for the best all-round company was taken by No. 4 Company (Surgeon-Captain J. Harper).

DEATHS IN THE SERVICES.

Brigade-Surgeon James Crosse Johnston, A.M.D. (retired), on the 23rd inst. He served with the 9th Regiment in the Crimea from January, 1855, including the siege and fall of Sebastopol and assault of the batteries (medal with clasp and Turkish medal).

The following is a list of medical men nominated by the Secretary of State for War as surgeons-on-probation for the Royal Army Medical Corps on the recommendation of the medical schools of the United Kingdom: E. V. Aylen, M.R.C.S., L.R.C.P., London Hospital; T. J. Potter, L.R.C.P. & S.I., College of Surgeons, Dublin; H. Rogers, M.B., B.Ch., Dublin University; T. F. Ritchie, M.B., Ch.B., Aberdeen University; W. J. S. Harvey, M.R.C.S., L.R.C.P., Guy's Hospital; A. J. Williamson, M.B., Ch.B., Edinburgh University; B. A. Craig, L.R.C.P. & S.I., College of Surgeons, Dublin; A. W. Sampey, L.R.C.P. & S.I., Richmond Hospital; J. C. Hastings, M.B., C.M., D.P.H., Edinburgh University; W. M. Browne, L.R.C.P. & S. Edin., Edinburgh; C. T. R. White, L.R.C.P. & S. Edin., Edinburgh; A. A. W. Merrick, L.R.C.P. & S.I., Queen's College, Belfast; D. O'Donoghue, L.R.C.P. & S.I., Catholic University School of Medicine.

Correspondence.

"Audi alteram partem."

"THE STATISTICS OF GASTRIC ULCER, WITH SPECIAL REFERENCE TO GASTRIC HÆMORRHAGE, ITS FREQUENCY AND FATALITY."

To the Editors of THE LANCET.

SIRS,—I have been both amused and surprised by some of Mr. Mayo Robson's comments on my lecture on the Statistics of Gastric Ulcer—amused because I note that while he heartily concurs with the facts and arguments I have advanced which tell in his favour, he refuses to admit any of my facts and arguments which are opposed to his conclusions, and surprised at some of his statements. In my lecture I endeavoured to consider impartially *all* sides of the statistical questions concerned, so far as they were known to me, and to be scrupulously fair in my consideration of Mr. Mayo Robson's views. I would again emphasise the fact that the question is one, not merely of academic and scientific interest, but of the very greatest practical importance, and that it is essential that the data on which physicians and surgeons will have to decide whether operative treatment for the arrest of hæmorrhage in cases of gastric ulcer is advisable or not should be as accurate as possible.

Mr. Mayo Robson accuses me of mere quibbling because, in contrasting the actual number of deaths registered in Leeds last year from gastric ulcer with the number of deaths which should, according to his estimate, have occurred in a population of 500,000, I pointed out that the population of Leeds was 431,287. To have contrasted the actual number of deaths from gastric ulcer which were registered in a population of 431,287 with the deaths which, according to Mr. Mayo Robson's estimate, ought to have occurred in a population of 500,000 would have been unfair to Mr. Mayo Robson; if I had not made the necessary corrections for the differences in population I would have laid myself open to criticism; and unless I had stated the actual number of the population my conclusions and calculations would have been unintelligible to your readers and might have been thought to be erroneous. To term this mere quibbling is hardly what I should have expected from Mr. Mayo Robson in a scientific discussion.

I agree with Mr. Mayo Robson in thinking that the statistics of Brinton with regard to the total mortality in cases of gastric ulcer and the statistics of Müller with regard to the mortality from hæmorrhage in gastric ulcer "have become classical," for they are more than 40 years old; but I differ from him in thinking that "they are accepted by all authorities on the subject to-day." It is true that they are still mentioned by many authorities, but I am not aware that any modern authority agrees with them—that any modern authority, with the exception of Debove and Regnault, who quote Brinton's figures apparently with approval,[1] agrees with Brinton in thinking that the total mortality in all cases of gastric ulcer is 50 per cent. (or anything like 50 per cent.), or with Müller that the direct mortality from hæmorrhage in cases of gastric ulcer is 11 per cent. (or anything like 11 per cent.).

If Mr. Mayo Robson had taken the *average* of the figures given by *modern* authorities I would have had nothing to say. My objection to his figures is that they represent the mean of the extremes, and that the maximum figures which he quotes (those of Brinton and Müller) should not, in my opinion, have been included, since they do not correctly represent the total mortality or the mortality from hæmorrhage in cases of gastric ulcer at the present day. The erroneousness of Brinton's estimate of 50 per cent. is shown by the fact that, if this estimate is correct, and if (as Brinton and Mr. Mayo Robson suppose) 5 per cent. of the whole population suffer from gastric ulcer, in a population like Leeds with 500,000 inhabitants, 12,500 persons, or one in every 40 persons (if children under five years of age are included), will die from gastric ulcer, or one in every 35 persons over five years of age (if children under five years of age, who rarely if ever die from round ulcer, are excluded) will die from gastric ulcer or some of its complications!

Mr. Mayo Robson does not accept my statement that gastric ulcer is more common in the hospital class than in well-to-do people and he takes exception to my basing this opinion upon clinical evidence, to which he says I have so much objected. Mr. Mayo Robson does not seem to realise that it is one thing to determine the exact (the percentage) frequency with which gastric ulcer occurs in the whole population, and that it is another and quite a different thing to determine whether gastric ulcer is more common in the hospital class or in well-to-do people. The clinical method cannot be relied upon for the former purpose, chiefly for the reason that, after the frequency with which gastric ulcer occurs in a given number of clinical cases has been determined, there are, so far as I know, no reliable figures to enable us to apply the result to the whole population. But it seems to me that the clinical method can quite well be relied upon for the latter purpose (to determine whether gastric ulcer is more frequent in hospital patients or in well-to-do people). The general practitioners throughout the country who are in the habit of dealing with both classes of patients (hospital and well-to-do) will, I fancy, have no difficulty in deciding whether my opinion on this point, which is based upon a large experience in general practice amongst all classes of patients, in hospital practice and in consulting practice, is correct or not. Further, all modern authorities are agreed that ulcer of the stomach is much more common in housemaids and female cooks (whom I include in the hospital class) than in any other class of the community. In speaking of the etiology of gastric ulcer Welch, for example, states: "Gastric ulcer is more common among the poor than among the rich. ..... The comparative frequency of gastric ulcer among needle-women, maid-servants, and female cooks has attracted the attention of all who have had large opportunities for clinical observation."[2]

Mr. Mayo Robson says: "I was very much astonished to find Dr. Bramwell making use of the Registrar-General's returns for the purpose of disproving the statistics I quoted, and I should like to ask if Dr. Bramwell really seriously argues that the Registrar-General's returns of deaths from gastric ulcer can be pitted against the statistics of such able physicians and keen observers as Brinton, Welch, Dreschfeld, Habershon, Müller, Lebert, Tricomi, and others?" I did not pit the Registrar-General's returns against the statistics of the authorities whom Mr. Mayo Robson quoted, but—and this is a very different thing—against the conclusions (based on the mean of the extremes) which Mr. Mayo Robson drew from those statistics. I have not refused to accept the conclusions of modern authorities (such as Lebert, Welch,

[1] Ulcère de l'Estomac, p. 101.
[2] Pepper's System of Medicine, vol. ii., p. 486.

Dreschfeld, and Riegel) which show that the total mortality of gastric ulcer is probably somewhere between 8 and 15 per cent., although, as I pointed out in my lecture, these statistics are for the most part based on hospital results, and although the proportion of deaths to the total cases of gastric ulcer treated is very much greater in hospitals than outside hospitals. I have not suggested that the Registrar-General's returns were strictly accurate—nor, so far as I know, does anyone claim that *any* of the statistics (mortality percentages) quoted by Mr. Mayo Robson are strictly accurate, while Brinton's estimate is certainly most inaccurate. I allowed for considerable additions to the figures, due to the fact that a certain number of deaths caused by gastric ulcer and its complications are registered under other headings. But what I do maintain is that, after making ample allowance for these sources of fallacy, the difference between the returns of the Registrar-General and the mortality which, according to Mr. Mayo Robson's estimate, should result from gastric ulcer is sufficiently great to show that Mr. Mayo Robson's figures must be incorrect. But, after all, the practical test of the correctness of Mr. Mayo Robson's figures in regard to the total mortality of gastric ulcer is that, according to him, one in every 80 persons (if children under five years of age are included), or one in every 69 persons (if children under five years of age are excluded), in a community of 500,000 persons will die from ulcer of the stomach or from some of its complications. I do not believe that this is the case, and I would ask, Do the readers of THE LANCET, whose experience in practice entitles them to judge, believe it?

Mr. Mayo Robson next says: "Dr. Bramwell should really be careful before he accuses anyone of making a serious error, especially when he pits his individual experience and opinion against the experience of the authorities quoted from and whose statistics I will again repeat," &c. What my individual experience and opinion are has nothing to do with the particular point at issue. That point is, Was Mr. Mayo Robson right or was he wrong in concluding that the figures which he quoted represented the mortality from hæmorrhage in those cases of gastric ulcer in which hæmorrhage occurs? Do the percentages which he quoted refer, or do they not refer, to *all* cases of gastric ulcer?

Mr. Mayo Robson's statement was very definite—viz.: "Hæmorrhage which according to different authorities occurs in a greater or less degree in from 50 to 80 per cent. of all cases of gastric ulcer and is, according to various authors, fatal when medically treated in from 11 to 3 per cent. (Müller, 11 per cent.; Welch, from 3 to 5 per cent.; Brinton, 5 per cent.; Debove, 5 per cent.; Steiner, 6·36 per cent.; Lebert, 3 per cent.; Dreschfeld, 3½ per cent.; and Rodman, 8 per cent.). If we take the average, 7 per cent. of deaths in cases of gastrorrhagia from ulcer will not be far from the truth. If this is worked out in the 500.000 population of a city like Leeds it means that of the 25,000 persons who have or have had ulcer 12,500 suffer from hæmatemesis, and of these 7 per cent., or 875, die."

My statement was also very definite. After pointing out that 7 per cent. does not represent the average of the figures quoted, but the mean of the extremes, I stated: "The percentages of deaths from hæmorrhage, which Mr. Mayo Robson quotes from different authorities, with, so far as I have been able to ascertain, the exception of Rodman, refer, not to the percentage of deaths in those cases of gastric ulcer in which hæmorrhage occurs (which Mr. Mayo Robson estimates at 50 per cent. of the whole), but in the total number of cases of gastric ulcer. If, therefore, 7 per cent. of all cases of gastric ulcer die from hæmorrhage, Mr. Mayo Robson's figures will have to be doubled; in other words, in a population like Leeds, say of 500,000, 1750 will die from hæmorrhage."

Mr. Mayo Robson adheres to his reading of the figures and so do I. Possibly the authorities named may have stated one thing in one place and another thing in another place. Possibly, therefore, both Mr. Mayo Robson and I may be correct. But there is no need to talk of possibilities when the matter is capable of easy proof. I would, therefore, ask Mr. Mayo Robson to publish the exact references (he, unfortunately, gave no reference in his paper) to the passages in the publications of Müller, Welch, Brinton, Debove, Steiner, Lebert, Dreschfeld, and Rodman, to which he referred. This will at once show which of us is correct or whether both of us are correct.

Mr. Mayo Robson quotes in support of his view the following statement of Fenwick—viz.: "Hæmorrhage from the stomach is a frequent cause of death in gastric ulcer. Out of 112 fatal cases recorded at the London Hospital, 18, or 16 per cent., died from hæmatemesis, while in another series of 298 necropsies on gastric ulcer we find that hæmorrhage occurred in 56 cases, or in 18·8 per cent." In answer to this I would point out that the frequency (percentage fatality) with which hæmorrhage is the cause of death in a series of *fatal* cases of gastric ulcer does not show the frequency (the percentage fatality) with which hæmorrhage is fatal in all cases of gastric ulcer. Because hæmorrhage is the cause of death in 18 per cent. of the fatal cases of gastric ulcer it does not necessarily follow that a *large* percentage of patients who are affected with gastric ulcer die from hæmorrhage; that this is so is shown by the statistics of the Edinburgh Royal Infirmary and of St. Thomas's Hospital given below. Further, the percentage of deaths from hæmorrhage in the series of fatal cases given by Fenwick is much greater than in some other series of fatal cases of gastric ulcer. Thus in 270 fatal cases of open ulcer (collected and analysed by Welch [3]), 27, or 10 per cent., died from hæmorrhage; and in 107 fatal cases which occurred in the Edinburgh Royal Infirmary and in St. Thomas's Hospital (see below) 10, or 9·3 per cent., died from hæmorrhage.

So far as I know, there is no reason to suppose that there is any material difference in the fatality of gastric ulcer or in the fatality from hæmorrhage in gastric ulcer in London and Edinburgh respectively. The fatality in the Edinburgh Royal Infirmary during the nine years, from 1892 to 1900 [4] inclusive, is shown in the following figures, for which I am indebted to Dr. A. L. Gillespie, our medical registrar. During the nine years (1892–1900) 891 cases of gastric ulcer were admitted into the medical and surgical wards of the Edinburgh Royal Infirmary; [5] of these, 858 cases were admitted to the medical wards and 33 cases to the surgical wards; of the total 891 cases, 61 died; of the 61 fatal cases 43 died in the medical wards and 18 died in the surgical wards. The percentage of deaths in the total 891 (medical and surgical) cases of gastric ulcer was 6·8; the percentage of deaths in the 858 medical cases was 5·01; and the percentage of deaths in the 33 surgical cases was 54 54 (three of the cases which died in the surgical wards were transferred from the medical wards for the purpose of operation). In the 61 fatal cases, hæmorrhage was the cause of death in six cases only. Consequently the percentage of deaths from hæmorrhage in the total 891 cases of gastric ulcer which were treated as in-patients in the Edinburgh Royal Infirmary during the period under observation was 0·67; in other words, during the nine years, 1892 to 1900 inclusive, only six cases of gastric ulcer died in the Edinburgh Royal Infirmary from hæmorrhage.

If these results are contrasted with those of St. Thomas's Hospital they will, so far as the mortality from hæmorrhage in cases of gastric ulcer is concerned, be found to be almost the same. The St. Thomas's Hospital results are as follows. During a period of 15 years (1884 to 1898) the total number of cases of gastric ulcer was 473; of these 473 cases of gastric ulcer 46, or 9·72 per cent., died; and of the 46 fatal cases four died from hæmorrhage; in other words, four out of 473 cases of gastric ulcer, or 0 84 per cent., died from hæmorrhage. But during the same period there were 82 cases of hæmatemesis, of which three died; in two of these there was no post-mortem examination; they may, perhaps, have been cases of gastric ulcer. If these two cases of fatal hæmatemesis are added (which may perhaps have been cases of gastric ulcer) the total mortality from gastric ulcer in St. Thomas's Hospital during the 15 years under observation would be 10·1 per cent. and the mortality from hæmorrhage in gastric ulcer would be 1·2 per cent. In other words, in St. Thomas's Hospital during a period of 15 years only four cases of gastric ulcer (actually returned as such) died from hæmorrhage; and if the two cases of fatal hæmatemesis (which may perhaps have been cases of gastric ulcer) are added only six cases of gastric ulcer died from hæmorrhage during a period of 15 years.

Consequently, in two of the largest and most representative hospitals in the country only 10 cases of gastric ulcer (or possibly 12 cases, if the two cases of hæmatemesis in

[3] Pepper's System of Medicine, vol. ii., p. 502.

[4] The nine years 1892-1900 are selected because there were no published reports before the year 1892.

[5] The figures do not include the cases admitted to the surgical wards during the last year (1900).

the St. Thomas's Hospital Reports, which may perhaps have been gastric ulcer, are added) died from hæmorrhage during a long period of years, giving a mortality from hæmorrhage in gastric ulcer of 0 73 per cent. (10 deaths from hæmorrhage in 1364 cases), or 0 87 per cent. (12 deaths from hæmorrhage in 1364 cases) if the two cases of hæmatemesis which were, perhaps, gastric ulcer are included. It is hardly necessary to point out that this mortality is very different from that which Mr. Mayo Robson estimates. Since Mr. Mayo Robson's address was delivered I have been actively engaged in trying to trace the after-history of all of the cases of gastric ulcer which I have treated in hospital as in-patients and seen in consulting practice. The results will be published in due course.

I am, Sirs, yours faithfully,

Edinburgh, March 19th, 1901. BYROM BRAMWELL.

"HOUR-GLASS CONTRACTION OF THE STOMACH": A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—"Hour-glass contraction of the stomach" has now become such a well-recognised term for a fairly frequent diseased condition that any attempt to dispute the term will be almost sure to lack approval. However, I venture to state that it is not a precise term if not a misnomer. I maintain that the more precise term both pathologically and clinically should be "hour-glass *dilatation* of the stomach consequent on some constricting band or contracting area." When the surgeon comes to operate on these cases he does not find a small contracted stomach but two or three dilated sacs produced as a result either of fibrous adhesions or of a contracted or contracting area according as ulceration is proceeding or past. If there are two sacs we may call one the "cardiac complement" and the other the "pyloric complement." The "cardiac complement" has been formed first by hypertrophy of the muscular coat of the stomach in its endeavour to pass its contents through a stenosed lumen; the hypertrophy has then been followed by dilatation according to the ordinary rule in hollow viscera. The "pyloric complement" dilates from a totally different cause—namely, an atonic and paralytic distension due to the accumulation in it of stomach contents which stagnate instead of passing on through the pylorus, for the simple reason that the proper peristaltic waves have been cut off or inhibited by the constricting band or contracting area of fibrous tissue. An accessory factor in the dilatation of both "cardiac and pyloric complements" is the accumulation in them of the gases of fermentation and their effect upon a degenerate muscular coat. Should there be three dilated sacs produced by two constricting bands or contracting areas then we may describe a "cardiac complement," a "pyloric complement," and an "intermediary complement." The "intermediary complement" dilates from the same causes as the "pyloric complement."

I am, Sirs, yours faithfully,

BERTRAM C. STEVENS, M.B. Durh., M.R.C.S. Eng., &c.

Leeds, March 18th, 1901.

"DIPHTHERIA ANTITOXIN USED SUCCESSFULLY BY THE MOUTH."

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a clinical note with the above heading published in THE LANCET of Feb. 9th. This mode of administering antitoxin is not quite new. In April, 1897, I had a patient, a little girl, who became so nervous and hysterical at the sight of the large hypodermic needle then used that I could not prevail upon her to let me give her an injection but she had no objection to take it by the mouth; and although this was a very severe case with high temperature and the soft palate and both tonsils were covered with membrane the patient made a satisfactory recovery. I have given it in this way in many cases since with the most satisfactory results, having had no deaths. I use Behring's preparation, giving from 1000 to 2000 units for a dose, which amount usually is sufficient. Prior to the case referred to I had not read or heard of this means of administering the remedy, nor had I heard of it since until I read the article above mentioned.

I am, Sirs, yours faithfully,

J. LINDSAY PORTEOUS, M.D. St. And., F.R.C.S. Edin

Yonkers, N.Y., U.S.A., March 13th, 1901.

"THE DUTIES OF HOUSE SURGEONS AT THE EAST SUFFOLK AND IPSWICH HOSPITAL."

To the Editors of THE LANCET.

SIRS,—I wish to add something further to Dr. Kay's letter published in THE LANCET of March 16th, p. 815. He makes reference to my interview with Mr. Elkington, the editor of the *East Anglian Daily Times*. The same morning I mentioned the matter *re* giving information to the press to Mr. H. Mason, vice-chairman of the weekly board. He said that he was afraid that I must give information to the press as the *East Anglian Daily Times* gave us puffs and that we could not afford to offend it. My reply was that if the hospital was properly managed it required no puffs, if improperly managed the sooner it was legitimately criticised the better, and that I could not see my way clear to give information to the press and regarded it as a breach of professional secrecy. I regret to say that in discussing the matter with some of the staff they adopted the extraordinary view that patients admitted into hospital were in receipt of charity and were not on the same footing as private patients. I entirely dissented from this view and said that in my opinion patients admitted into hospital were as much entitled to professional secrecy as private patients.

Mr. Elkington's attitude at the meeting of the board of management, which decided our dismissal, is in my opinion somewhat vindictive, considering the dual position he occupies—i.e., editor of the *East Anglian Daily Times* and a member of the weekly board. In his speech to the board supporting our dismissal he asked if ethics brought the hospital money. He also went on to say that unless the house surgeons were dismissed he must seek such information as he required from the proper source—the patients' relatives.

I am, Sirs, yours faithfully,

March 19th, 1901. C. C. WORTS, Second House Surgeon.

"THE ROYAL ORTHOPÆDIC HOSPITAL."

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a letter published in your issue of March 23rd from a "Hospital Governor" relative to certain matters that have recently been considered by the committee of this hospital regarding the disposal of its present site.

I have no intention of entering into a controversy with your anonymous correspondent in the columns of your journal, but I write to protest against important business and negotiations conducted by hospital committees being prematurely discussed in the press. If such methods were legitimate then meetings of committees might as well be open to the public and to the press.

Your correspondent deals mainly with two points that were before my committee on the 14th inst. One is stated quite inaccurately and the other is not fully set out so as to merit a proper judgment upon it. Sirs, the axiom that "half the truth is often worse than an untruth" is well exemplified in this case.—I am, Sirs, yours faithfully,

March 26th, 1901. TATE S. MANSFORD, Secretary.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Great Increase of Plague.

A THEORY was started about three years ago that the cold weather, by driving the people into their houses, favoured the spread of plague. It was apparently constructed to explain the particular outbreaks in Bombay and the idea still seems to linger in the popular if not in the official mind. Subsequent experience does not support this view as the great rise in plague mortality of the past two weeks with the rise in temperature shows. During the exceptionally cold weather plague did not make much headway. The outbreaks in Calcutta, Karachi, Poona, as well as the later ones in Bombay, ought at any rate to convince anyone that an outbreak of plague will develop in the hot weather as virulently as, if not more so than, in the cold.

The total number of deaths from plague in the whole of

India last week were 4377, against 3415 in the preceding week and 2137 in the corresponding week of last year. The mortality is therefore double what it was a year ago. Bengal continues to be the worst infected province, but the disease is rapidly increasing again in Bombay. The figures are: Bengal, 2491, against 2058 in the preceding week and 782 in the corresponding week of last year; Bombay city, 845, against 588, and the district 471, against 360; Madras, 138, against 44 (all in the Salem district); North-west Provinces, 44 (in the Benares and Ballin district); Calcutta. 129, against 71; and Bengal district, 2491, against 2058. The features of the epidemic for the week are its great increase in Bombay city, its continued virulence in the Patna district of Bengal, its development in Calcutta, and its fresh outbreak in Benares and Karachi. The municipality of the latter city has addressed the President of the Plague Committee to the effect that it cannot find funds for the Plague Committee, and that either plague measures must practically cease or must be paid for by Government. There is little prospect of plague disappearing and expensive and elaborate organisations have proved unavailing. Cholera kills every year far more people, and yet, beyond purification of the water-supply, little is done. Possibly if Government would devote some of the money now expended on plague measures to original scientific experiment we should probably obtain some more tangible results.

Feb. 14th.

The Continued Increase in the Plague Epidemic.—The Death of Colonel Maitland.—The Pasteur Institute and Contributions from Local Bodies.—The Continued Famine.

I have to record a still further increase in the mortality from plague throughout India. The week's record shows 6309 deaths. The Bengal Presidency heads the list with the alarming total of 4353, of which the Patna district contributed 1736. In Calcutta there has been a rise from 233 to 287. Since these figures were published the deaths have very considerably increased and the disease is rapidly extending all over the city. In Bombay city also the plague continues to claim more and more victims. Out of the total mortality of 2495 last week there were 1118 deaths from plague. The present death-rate in Bombay is 158 per 1000 per annum. In Karachi the outbreak is slowly developing, as is usual during its early stages. There have been 100 cases and 66 deaths up to Feb. 26th. There is no particular change to note from other parts.

Colonel Maitland who was killed with his syce during the attack made on the Somali Expedition belonged to the Indian Medical Service. Prior to leaving for Africa he was attached to the Marine battalion in Bombay. He was greatly esteemed and respected by everybody and great sympathy is felt for Mrs. Maitland.

It will be remembered that the Pasteur Institute of India appealed some time ago to various local bodies, municipal and district boards, for subscriptions, but on the subject of contributing funds to this purpose many of these corporate bodies hesitated as being beyond their powers. Doubt as to the power of municipalities in India to contribute has been set at rest by a decision of Government which has held that municipalities according to the Act can contribute, but that district councils cannot do so without the sanction of the local government.

The continued famine is due to the failure of rains in the districts of Guzurat, Sholapur, and Ahmednagur. Adequate preparations are being made by the Bombay Government to tide over the coming season, but the absence of rain for so long threatens the supply even of drinking-water both for man and beast. It is said that the wells and tanks are failing. Already it has been thought advisable to deepen many wells and relief works of other kinds are being arranged for. As the harvest in other parts has been good there will be plenty of good grain available. It is only a question of distribution.

Feb. 27th.

Early Returns of the Recent Census.—The Plague Epidemic.—The Biological Treatment of Sewage.

Contrary to expectation, many places in India show an actual diminution in population as compared with the census of 1891, but only a few of the returns have as yet been published. On the other hand, there are several instances of extraordinary urban increase. Howrah, on the opposite bank to Calcutta, shows an increase of 34 per cent., Rangoon an increase of 29 per cent., and Naina Tal an increase of 45 per cent. Delhi, Cawnpore, Jubbulpore, and Lahore also show increases, but in Lucknow, Benares, Bangalore, and Bombay there have been small declines. In the three latter cities plague has probably been the cause. The city of Bombay has possibly lost 100,000 people from the plague and the census rough totals show the populations to have fallen off by 50,000 since 1891. The number of inhabitants is now 770,000. Famine and the general high death-rate in other parts of India will have prevented any very large increase in the whole population.

The epidemic of plague continues to spread and to intensify in certain areas. There were 6927 deaths throughout India from plague last week—nearly double the mortality of the corresponding week last year. The increase over the preceding week is 618. The most noticeable feature of the returns is the great rise in Calcutta—viz., from 287 deaths to 405. The disease has extended in the North-West Provinces, where Benares, Ballia, and Jaunpur are all now more or less affected. They return 283 deaths. There is a slight decline in the districts of Patna, Saran, Gya, and Monghyr in Bengal, but nearly 4000 deaths were returned from them. The increase of mortality in Calcutta is practically all accounted for by plague, and there must be a large proportion of the cases seen by the authorities during life. In Bombay city, on the other hand, with a weekly mortality of 2615 from all causes, only 1080 are returned as due to plague. The average mortality being under 700 there are thus 800 extra deaths unaccounted for. In all probability the whole of the excess is due to plague—making the plague mortality nearer 2000 than a little over 1000, as published in the returns. For the years 1896 to 1900 there have been recorded in Bombay city 269,536 deaths from all causes. The mean of previous years shows that the mortality should not have exceeded 140,000. This excess of 129,536 is only partly (about a half) accounted for by the plague deaths reported which number 59,136. From the imperfect registration of the causes of death it is almost certain that the official returns are incorrect and it is probable that the death-roll from plague in Bombay city since the first outbreak amounts to over 100,000 people.

The biological treatment of sewage is being adopted at several places in India. One of the latest towns to employ it is Howrah, opposite Calcutta. The process employed consists in passing the highly foul and offensive sewage through a specially designed primary filter constructed on the "Scott-Moncrief" plan, by which upward filtration is obtained. The effluent is then passed through bacteria beds. It is led over a broad weir on to the beds. The latter consist of layers of earth and fine cinders and are about three feet in depth. The scum of the bacteria beds is scraped off every week or so. The results are said to be economical and satisfactory.

March 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Glasgow.

THERE seems at last to be a substantial basis for the expectation that the epidemic is yielding to the active measures that have been prosecuted with a view to prevent its spread. The new cases admitted during the week ending March 24th numbered 63, a gratifying decrease on the previous record and a justification of the recorded anticipation of the health officials to the effect that recent evidences of increased activity of the disease were likely to be of a temporary character. Various amateur suggestions for dealing with the epidemic continue to be made through the public press and otherwise, and here and there certain details of the official proceedings have received a not altogether sympathetic criticism. But the great body of public opinion offers an appreciative support to the medical officer and other officials who have been called on to sustain an enormous burden of responsible work.

The Municipalities and the Health of the City.

In a recent lecture on this subject Dr. Erskine, who is a member of the Glasgow Town Council, gave an account of the establishment and development of the municipal health department. Speaking on the present epidemic of small-pox he compared it with the outbreaks in 1873 and 1874. In these the deaths numbered 228 and 214 respectively, whilst

the death-roll of 1900–01 is 190. The recent outbreaks of plague and small-pox showed that in certain respects the arrangements for guarding the health of the city are far from satisfactory. In the first place it was clear that the medical inspection of vessels arriving in the Clyde was quite inadequate, and reform in this respect was imperative. Dr. Erskine also criticised the existing small-pox hospital accommodation. This, he urged, should never have been placed in such close proximity to the General Fever Hospital. Not only is the hospital from 30 to 40 yards from the general wards but it is only distant some 60 yards from dwelling-houses. Dr. Erskine stated that he had pressed this question on the attention of the Health Committee more than two years ago but it had been completely ignored.

Professor John Glaister on Sewage Purification.

In a lecture delivered to the Glasgow Philosophical Society on March 20th Professor Glaister described the various methods of sewage purification and urged that the selection of a scheme for any populous place should be made on the ground of its suitability on practical and economical grounds to the district concerned and not on any abstract merits which one scheme was supposed to possess over another. The practical difference in efficiency between any of the schemes now in vogue was not, he considered, sufficient to justify the expenditure of large sums of public money in order to replace one system by another, for less depended on the system than on the manner in which it was worked. In dealing with the corporation sewage works at Dalmarnock Professor Glaister expressed the opinion that iron should be more extensively used as a precipitating agent. Criticising a recent statement of the city engineer that in the new sewage works precipitation would not be accompanied by filtration, the lecturer doubted the wisdom of this decision and the possibility under the circumstances of producing a satisfactory effluent. In the latter part of his lecture Professor Glaister referred to the bacterial systems of sewage purification and pointed out the disadvantage entailed by the expense involved in the purchase of large tracts of land for the contact beds. Further, no scheme yet devised could prevent the passage of pathogenic organisms through the beds into the effluent.

The Prevention of Consumption.

At the instance of the Glasgow Medico-Chirurgical Society and the Corporation Committee on Tuberculosis a public meeting was held in Glasgow on March 22nd to consider the propriety of establishing a local branch of the National Association for the Prevention of Consumption. The Lord Provost presided and there was a good attendance of medical men and others. The proposals adopted by the meeting were in favour of the object for which the meeting was summoned and in support of the establishment of sanatoria for the treatment of consumptive patients, and a committee was appointed to carry out these resolutions. The principal medical speakers included Professor McCall Anderson, Professor J. Glaister, Professor R. Stockman, Dr. Alexander Robertson, Dr. Lindsay Steven, and Professor H. E. Clark, The Lord Provost, Principal Storey, and Sir J. Neilson Cuthbertson also spoke in favour of the above proposals. Sir Hector Cameron, who was to have proposed one of the resolutions, was unavoidably absent.

University of Glasgow.

The University plans for the erection of a surgical laboratory at Gilmorehill have passed the Dean of Guild Court and the authorities, therefore, have the power to begin building when it suits their convenience. It is somewhat of a surprise to learn that the surgical laboratory is to be one of the first to be erected. Its principal function must necessarily be the promotion of research work, and it would seem not unreasonable to suggest that this might wait until the claims of the departments in which facilities for practical teaching need improvement had been satisfied. The University are asking the city merchants to subscribe liberally to promote a scheme of practical laboratory accommodation; their appeal might address itself more successfully to business instincts were it accompanied by a detailed statement of the manner in which the money is to be expended. It is reported that no successor in the meantime is to be appointed to Dr. Thomas Reid as lecturer on diseases of the eye. The endowment, it appears, is not definitely attached to the lectureship and is likely to be employed in connexion with a lectureship on another subject. There are vacancies for examiners in clinical medicine and clinical surgery.

March 26th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Sanitary Association.

THE annual meeting of the Dublin Sanitary Association was held on March 21st, Dr. Charles Moore, the President, being in the chair. Mr. R. Brien Furlong moved the adoption of the report, and Sir William Thomson, in seconding the motion, alluded to the number of dairy yards in the city, and to the fact that there could not be proper inspection of the 40 or 50 private slaughter-houses which were still permitted to exist. He said that he looked upon the want of proper control of the tenement houses as one of the chief causes of the exceptional mortality which prevails in Dublin from time to time. Sir Charles Cameron said that he was in agreement with a great deal of what Sir William Thomson had said as to dairy yards and slaughter-houses, but it should be remembered that in Dublin there were vested interests in connexion with those houses. The corporation had power to purchase the interests of the proprietors of the slaughter-houses, but they had no power with regard to the dairy yards, and at present the law did not permit them to refuse a licence for a new dairy yard even though it should be at the back of a gentleman's house. When he (Sir Charles Cameron) first became medical officer of health of Dublin there were 500 dairy yards in the city and that number was now reduced to 200. Many of the slaughter-houses had been disposed of. As to the tenement houses, many of them were owned by absentee landlords representing families that lived in Dublin 200 years ago. In Turgan-street a house belonging to a landlord who lived on the continent was let to a tenant who sublet it to a dozen others. Out of a total of 7000 tenement houses the corporation had obtained orders to close 3000, and of those that had been closed 1000 had never been rebuilt. In conclusion, he admitted that the general death-rate of Dublin was exceptionally high, but the death-rate from preventable diseases had been slightly below the average in 30 English towns.

The Hospitals and Convalescent Homes of Dublin.

At the annual meeting of the governors and subscribers of the convalescent home, Stillorgan, held on March 11th, Sir Frederick Falkiner, Recorder of Dublin, who presided, took the opportunity to make some interesting remarks in reference to the hospitals of the city. He said that Dublin was the best hospitalled city in the world and at the same time the most over-hospitalled. He did not think that many people knew that there were more hospitals in Dublin than in London with 12 times its population, and five times as many as in Edinburgh with twice its population. The work, moreover, of the hospitals of Dublin "was splendid." On another and more recent public occasion the Recorder stated that in his opinion the hospitals should not depend entirely on the subscriptions and bequests of the charitable, but that the patients who could afford it should be expected to pay some small sum, such as a few shillings per week.

The City of Dublin Hospital.

A deputation, consisting of Dr. Benson, Dr. A. R. Parsons, and Mr. Fry, representing the board of the City of Dublin Hospital, recently waited on the Pemberton Urban Council in reference to the latter's request for representation on the governing body of the hospital. The deputation explained that under a deed the provisions of which could not be altered the board consisted of 21 members, seven from the medical profession and 14 lay members. At present there was no vacancy, but a resolution had been passed that the first vacancy that arose among the lay members of the board would be offered to that council, the members of which could nominate a representative. The council considered this explanation as being satisfactory.

Royal University Graduates' Dinner.

The first annual dinner of the Royal University Graduates' Association was held in Belfast on March 19th, when there was a large and influential attendance. The President of the association, Dr. W. A. McKeown, was in the chair. The toast of "The King, the Queen, and the Royal Family," proposed by the chairman, having been drunk, the editor of the *Northern Whig*, Mr. J. R. Fisher, B.A., proposed "The Lord Lieutenant and Prosperity to Education in Ireland," to which Sir James Musgrave, Bart., replied. The main toast of the evening, "The Royal University of Ireland," was given by

Dr. McKeown. Having referred to what the Royal University had done for education in Ireland, both for men and women, and to the high standard of its examinations, especially in the faculty of medicine, he blamed the Government for making appointments on the Senate of persons who were actually hostile to the Royal University instead of persons who would do their best to make it more successful than it was. He said that at present fully 60 per cent. of those who obtained the Royal University degree in arts had been trained in private colleges or by private study. They must insist that the new Commission should be composed of absolutely impartial persons His own idea was that the associated colleges should be strengthened, more liberally endowed, provided with halls of residence, and made constituent colleges of the Royal University with direct representation on the governing body of the University. The Rev. Dr. Nicholas (President of the Belfast Methodist College) responded, and Dr. J. Walton Browne, one of the senators of the Royal University, also said that the senators from the north of Ireland had been instrumental in effecting that no examiner in medicine was permitted now to give any question at the examinations the answer to which could not be found in any of the various text-books in use throughout the United Kingdom, and secondly that no examiner in clinical subjects should be allowed to examine the students whom he taught. He (Dr. Browne) held that the clinical examinations should be conducted within the walls of the University and not at the Dublin hospitals, and he also hoped to get students their final degree without having to go to Dublin for three months for private tuition. The Rev. J C. Heuston proposed "The Queen's Colleges and the Affiliated Colleges of the Royal University," to which Mr. G. Hume, M.A., K C., and Mr. C. Scott, C.E , responded. The Rev. Professor Leitch, D.Lit., proposed the toast of "The President of the Royal University Graduates' Association," to which Dr. McKeown replied.

Down District Lunatic Asylum.

At a meeting of the Committee of Management held on March 22nd it was reported that dysentery, for some years endemic, now seemed to have assumed an epidemic aspect in the asylum. Notice was given of a motion to provide isolated hospitals for patients suffering from infectious diseases and the medical superintendent, Mr. M. J. Nolan, was directed to make inquiry respecting iron hospitals to accommodate about 20 patients with small kitchens connected therewith.

(FROM OUR OWN CORRESPONDENT.)

Emergency Operations in Hospitals: The Responsibility of Operators.

THE Consultative Committee of the Assistance Publique, having been approached by various surgeons and accoucheurs as to what course they should pursue in the event of a patient refusing operation in a case of emergency, has returned the following detailed answers:—1. If a woman in labour who is under treatment in a hospital, being in full possession of her faculties, refuses an operation, the accoucheur in charge, after having laid the matter fully and fairly before her, should give way to her definitely expressed opinion. 2. If she only consents to be operated upon under certain definite conditions the accoucheur should also defer to her opinion, unless such conditions are manifestly unacceptable in themselves, or are against the rules of his art, or of such a nature as to make the operation more dangerous than useful. Under these last-mentioned circumstances the accoucheur ought to do nothing. 3. In an exceptional case, where by reason of the general or accidental condition of the patient she cannot be considered as being in full possession of her faculties, the accoucheur should act according to his moral responsibility, after, that is, having satisfied himself of the need for an operation and having informed the husband or in default of him the nearest relatives. In such a case the operator will not be responsible either under the criminal or the civil law, unless it should turn out that he has been guilty of evident malpraxis or has not acted in accordance with the generally accepted rules of his art. Many similar questions came before the committee and were treated as follows. The question was asked, How should the surgeon to a hospital act in the case where an immediate operation involving risk to life in a child is necessary and where there is no time to obtain the consent of the parents? The committee answer to this that in the case of urgency the surgeon can, and should, upon his own moral responsibility perform an operation which is considered to be necessary to be performed with a view to saving life, even though time is lacking to obtain the consent of the parents, but that if possible his opinion should be backed by that of his colleagues at the hospital and that the director of the hospital should be then and there informed of the operation. Under such circumstances the surgeon will not be liable to proceedings under either the criminal or the civil law unless it can be shown that he committed gross errors either of diagnosis or of operative technique. Another question was the following:—How far can a surgeon rely on the expressed wish of a child who has been told that he must undergo an operation? The committee answer to this that the surgeon must respect the liberty of the subject, whether of an adult or of a child, provided that such person be capable of giving an opinion and that the opinion be that given by the conscious exercise of a free will (*volonté consciente*). They say that in such a case the parents cannot impose their will on the child, whether in favour of or against surgical interference, but that the surgeon would do well to take the advice of his colleagues. With regard to the following question, Supposing that the parents disagree as to the necessity for an operation on a child, what should the surgeon do? the committee reply that the father's will should prevail. The final question ran, Is it either possible or becoming for the administration to lay down rules of conduct for surgeons and accoucheurs in such delicate and difficult questions as those cited above? To this the committee reply that any such rules would be the cause of grave difficulties without any compensating advantages. It is necessary for the interest of the patients and of the administration itself, and for the dignity of the medical profession, that the skilled professional worker should have perfect liberty of action—that is to say, upon his personal responsibility.

Mortality in France from 1886 to 1898.

For some years past the administration has endeavoured to get together demographical statistics, especially those of the causes of death in French towns with a population of over 5000 souls. Statistics covering a period of 13 years—namely, from 1886 to 1898—have been drawn up by M. Paul Roux, assistant keeper of the Bureau of Hygiene. He has been assisted by M. Henri Reynier, and they have issued a report which M. Monod has brought before the Academy of Medicine. The towns with more than 5000 inhabitants number 584. They are divided into six groups according to population, Paris forming by herself the first group. The total population comes to 12 848,235 inhabitants, nearly exactly one-third of the total population of France, which is 38,268,011. The report contains 14 tables in colour, which show for every group and for every town with over 60,000 inhabitants the number of births, of still-births, and of deaths. There are also shown the number of deaths due to epidemic diseases, to tuberculosis, to bronchitis, and to pneumonia, together with the infantile mortality. The most important conclusions to be drawn from the figures are as follows:—1. The steady diminution of the birth-rate, compensated in a slight degree by a small diminution in the death-rate. It must be here observed that the expansion of a race cannot be measured solely by the birth-rate or the death-rate but by the difference between the two. Now in France this difference is extremely small, very much less than that which exists in any other country of which the statistics are known. 2. There is a perpetual emigration from the country to the town, so much so that during the decennium 1886–1896, while the total population of France increased only by 0·89 per cent., the increase in towns of over 5000 inhabitants was 11·52 per cent., which obviously implies a diminution elsewhere. This percentage rises with the population of the towns, so that while it is 1·3 in towns of from 5000 to 10,000 inhabitants, in towns with over 30,000 inhabitants it rises to 18 or even 20 per cent. 3. There is a marked decrease in the number of deaths due to epidemic disease. 4. The number of deaths due to tuberculosis is almost stationary. 5. The infantile death-rate is very high. The mean of the birth-rate for the period 1887–1890 was 24·05 per 1000, which fell during the period 1896–1898 to 22 90, a fall of 1·15 per 1000, or for the urban population of 12,000,000 a fall in the births of 14,700

per annum. The mean annual death-rate was for the period 1886–1890 24·56 per 1000, while for the period 1896–1898 it had fallen to 21·36, a fall of 3·2 per 1000. The total fall in the epidemic death-rate was 15,350. Deaths from diphtheria decreased by 5650, from typhoid fever by 3000, from small-pox and measles by 2800, from whooping cough by 900, and from scarlet fever by 400. As regards tuberculosis, the reports are as yet incomplete, but it will suffice to remark that the number of deaths headed "cause unknown" or of those not officially certified are much in excess of the deaths from tuberculosis, and probably a great number of the uncertified deaths are due to tuberculosis. The infantile mortality during the period 1896–1898 reached the enormous figure of 247 deaths per annum for every 1000 children under one year of age, but during the period 1887–1890 the deaths numbered 317. Out of 25,539 deaths, infantile diarrhœa is responsible for 10,189, a percentage of 39·9. Every municipality and medical man should do their utmost to make these statistics as complete as possible, for the advantages which will thus accrue to the hygiene of the country are obvious.

The Dangers of Anæsthesia by Injections of Cocaine into the Spinal Canal.

At a meeting of the Academy of Medicine held on March 19th M. Reclus gave an account of certain inconveniences and dangers which have been observed to accompany anæsthesia by the spinal injection of cocaine. Sometimes owing to various causes no anæsthesia or only a transitory one is produced. Sometimes, too, the practice brings about trembling, nausea, vomiting, paralysis of the sphincter, transitory paraplegia, intense headache, or even severe attacks of fainting. Death has sometimes occurred, as in the cases reported by Humbert, Dumont, Jonnesco, King, and others. The method, therefore, cannot be considered as being without danger.

March 26th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

General Staff Surgeon Dr. von Coler.

THE seventieth birthday of General Staff Surgeon Dr. von Coler, chief of the army medical department, was celebrated by the members of the army medical corps on March 15th. All well-wishers to the army medical corps will be glad to hear that Dr. von Coler, notwithstanding his advanced age, will continue to hold his appointment. The *Deutsche Medicinische Wochenschrift* rightly says that the army owes very much to the chief of the medical department, because during the last 20 years the amount of sickness in the army has decreased by 30 per cent. and the death-rate by 50 per cent. The army medical school has received special attention from him, and he has been the means of providing it lavishly with every requisite for modern scientific research. Among the various administrative questions ably dealt with by him not the least important was the making of arrangements for systematic post-graduate study by the medical officers of the army. All these officers have been required from time to time to attend a series of lectures and practical demonstrations specially delivered for them in Berlin and the other university towns, and the larger public hospitals have been induced to give facilities for young medical officers of the army holding assistant surgeoncies and other similar appointments for periods of one or two years. He favoured the publication of scientific researches as much as possible, and a great many celebrities in various branches of medical science served at first in the army medical corps—such men, for instance, as Professor Behring, Professor Lœffler, Professor Gaffky, Professor Goldscheider, and many others. He has been a strenuous upholder of the principle that the position of the medical officers in the army should be in accordance with the importance of their services. Dr. von Coler, who had himself the rank of a lieutenant-general, was the means of obtaining adequate military rank for them and of bringing them to be looked upon as comrades by the other officers. His principal merit, however, consists in the fact that he has never ceased to take an active interest in medical science, and that he has never allowed his subordinates to forget that they were not only military officers but also medical men. The members of the army medical corps have commemorated the seventieth birthday of their official chief by issuing under the designation of the "Coler Library" a series of publications representing every branch of medical science and written exclusively by present and past members of the corps. The first six volumes are as follows: A Treatise on Diphtheria, by Professor Behring; History of Small-pox and Vaccination, by Dr. Kubler; A Study on the Physiology of Marching, by Dr. Schumburg; Physical Methods of Treatment in Internal Diseases, by Dr. Buttersack; Surgical Operations in War, by Professor Fischer; and Aural Operations, by Professor Trautmann. Surgeon-General Dr. Schjerning acts as editor of the "Coler Library."

German Balneological Society.

The German Balneological Society held its annual meeting at Berlin from March 8th to 11th, under the presidency of Professor Liebreich. The proceedings began with an inaugural address delivered by the chairman, who commented on the great development of spas and health resorts in Germany. He spoke in favour of recent views according to which balneological treatment at spas ought to be resorted to more for prophylactic purposes than for the cure of disease already established. Artificial mineral waters, he said, would never be so efficacious as the natural products, notwithstanding the progress of chemistry, but a course of treatment at any spa, however celebrated, would be useless if not controlled by a competent medical man. He was glad to know that balneology had become a science like other branches of medicine.—Professor Kisch of Marienbad spoke on the treatment of gout by water containing salts of lime which diminished the excretion of phosphates and urates. Springs like the Rudolfsquelle at Marienbad, the Arminiusquelle at Lippspringe, and the Helenenquelle at Wildungen were therefore valuable in nephrolithiasis, in vesical calculus, and in gout. These waters had, moreover, a diuretic action.—Dr. Pariser of Homburg read a paper on Cholelithiasis. He warned his hearers against methods by which gall-stones were to be discharged from the gall-bladder into the duodenum. A total evacuation of the gall-bladder was never obtained and the sufferings of the patient were increased by the treatment. Cholelithiasis might terminate in spontaneous recovery, because at necropsies calculi were very often discovered in the gall-bladder of persons who had never complained of any pain. In Dr. Pariser's opinion the best way of guiding a case into this latent stage was to keep the patient in bed and to treat the attacks of colic with narcotics.—Dr. Frankenhauser of Berlin read a paper on the Administration of Medicines with the Aid of Electricity. When the electrodes of a galvanic battery moistened with a saline solution were put on the skin a certain quantity of the salt made its way through the skin and passed into the circulation, the amount depending on the strength of the current. A rabbit might be poisoned by using an electrode moistened with hydrocyanic acid. The practical use of these experiments was only small because no more than a small quantity of any drug could be absorbed in this way; Dr. Frankenhauser had, however, succeeded in producing local anæsthesia by cocaine applied in this manner.—Professor Kolle read an address on new researches in bacteriology and serum diagnosis. Immunity of an organism against the virulent action of bacteria might be obtained by the administration of antitoxic substances, as, for instance, in diphtheria by the injection of diphtheria antitoxin. Another kind of immunity was obtained when the organism had the power of destroying bacteria spontaneously by dissolving or coagulating them so that they lost their toxic action. In the course of his researches Professor Kolle had made some interesting discoveries as to the toxic action of the red corpuscles of the blood of certain animals. It had been known for a long time that blood of a given animal injected into an animal of a different description produced a toxic effect, and if after the injection the animal survived it now became immune against the blood of the same species. Rabbits might in this way be made immune against human blood, and if an injection of human blood was given to a rabbit thus immunised the red corpuscles of the injected blood were dissolved and rendered harmless, whereas if pigeon's blood was injected into the same animal it continued to be toxic. There was one interesting exception. An animal immunised against human blood was also to some extent rendered resistant to the blood of monkeys—a new proof of the narrowness of the dividing line between the simiæ and the human species.—Professor Winternitz of Vienna

spoke on the subject of treatment by exposure to electric light. Applied in this manner the electric light sometimes caused great pain, but this complication was completely avoided when the electric lamps were provided with red glass so that the chemical rays were absorbed. When patients took the so-called "sunlight baths" they ought to have coverings made of red cloth. This method was very ancient; it was recorded that in the middle ages patients suffering from small-pox were treated by exposure to the sunlight, their coverings being only of red materials.—Professor Liebreich in the discussion alluded to Dr. Finsen's treatment of lupus by electric light. The cases shown before the medical congress at Paris were by no means completely cured, but showed only a temporary improvement such as might follow the employment of other methods.—Dr. Munter of Berlin thought that phototherapy was contra-indicated in gout; he had observed the fits to become more severe during treatment than they were before.—Dr. Winkler of Neundorf recommended sulphuretted springs in psoriasis, acne, and furunculosis. With regard to eczema only chronic cases could be treated in this way; acute eczema was aggravated by this treatment.—Other papers read before the congress dealt with the hydrotherapy of measles, scarlet fever, and neuroses; "winter cures" in the Alps; the action of mud baths; physical methods of treatment in asthma and tuberculosis; the treatment of agrypnia; the food in heart disease; and many other subjects.

March 25th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The International Sanitary Council.

THE difficulties which arose between the Turkish Government and the International Sanitary Council in connexion with the appointment of an inspector-adjoint have at last come to an end. The Turkish Government now shows a disposition to assent to the inspector-general of the Sanitary Board, as well as the inspector-adjoint and the chief accountant (Muhassebedji), being appointed by the Superior Sanitary Council, which, according to the stipulations, appoints and dismisses the sanitary officials. The Sanitary Council will therefore agree to the appointment of Dr. Zitterer, whom the Turkish Government has made inspector-adjoint, but only on condition that the Government shall not hereafter endeavour to encroach on the rights of the Superior Sanitary Council and shall sanction only the appointments that this council makes. Dr. Zitterer is a graduate of the medical school of Constantinople, having taken his degree more than 40 years ago. At that time medical instruction was given in the French language and the teachers were professing Christians, but at present medical instruction is given in the Turkish language, the medical literature of which is not very rich.

Precautions against the Plague.

At the meeting of the Superior Sanitary Council held on March 5th it was resolved that hides and skins should no longer be regarded as capable of conveying plague, cholera, or yellow fever. No restraint will therefore be placed by the sanitary officials on their importation into the Turkish Empire.

Dinner to Dr. Torel.

Dr. Torel, medical officer of the French despatch boat stationed here, has had a seat on the Superior Sanitary Council for about two years as a French sanitary representative. Dr. Mirabel, médecin-en-chef des colonies, has now been appointed to this post and Dr. Torel is consequently about to return to France. His absence from the council will be much regretted, and his colleagues, as a mark of their esteem, have entertained him at dinner at the Cercle d'Orient, this being the first dinner given in honour of a member quitting the council.

The Antirabic Institute.

In recognition of Louis Pasteur's discovery of the antirabic treatment Sultan Abdul Hamid II. sent him the Grand Cordon of the Order of Medjidieh and a donation of 500 liras for the Pasteur Institute in Paris. Dr. Zoeros Pasha, by whom the decoration was conveyed to Paris, was instructed to make himself acquainted with the method of preparing the antirabic virus and with the other details of the treatment, and on his return to Constantinople he was appointed director of the Antirabic Institute here. Unfortunately, in consequence of some intrigue, he was compelled to resign his post and two new directors, both of them French medical men, have since that time been successively at the head of the institute. The results of the treatment of rabies appear to be less successful now than they formerly were and a painful impression has been recently created by the death of the director of the Greek school at Tatavla, a suburb of Constantinople. He applied at the Antirabic Institute the day after being bitten by a rabid dog, but in spite of treatment he died on the nineteenth day after the receipt of the bite. The case was discussed at a meeting of the Imperial Medical Society and was said by the director of the institute to be one of paralytic rabies.

Small-pox.

Small-pox has almost disappeared from Constantinople. At Medina, however, from the beginning of November, 1900, to the end of January, 1901, there have been 143 deaths from this disease.

March 20th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Report of the State Board of Charities for New York for the Year 1900.

THIS report is an extremely voluminous document containing some 180 pages. It is of special interest this year, it being by no means unlikely that it will be the last issued by the board as now constituted, a Bill having been brought in, greatly favoured by Governor Odell, which will wholly alter the present methods of distributing and supervising the charities of the State. From the report recently published it is gathered that the recommendations for appropriations to the State institutions within the board's jurisdiction amount to $1,733,755 (£346,751), the amount recommended for maintenance being $1,108,800 (£221,760) and for extraordinary expenses, mainly for construction work, $624,954 (£124,991). A new table of statistics in the report shows the number of inmates in the 11 State institutions subject to the visitation and inspection of the board to have been 4250 on Sept. 30th, 1900. Most of these institutions appear to be in a fairly good state, exhibiting marked improvement since the last report. The New York State Soldiers' and Sailors' Home at Bath, according to the report, cannot be in a very promising condition. It is disgracefully overcrowded and new members are constantly seeking admission. The board recommends the erection of new barracks. The most serious evil at this home, however, is the presence of 14 public-houses, mostly of low order, at the entrance of the grounds. These are supported mainly by the pension moneys of the members of the home and with the well-conducted canteen on the institution grounds should be unnecessary. The report announces that a State hospital for the care of dependent crippled and deformed children, the measure for establishing which became law in April, 1900, is now in working order, but that the institution is hampered for lack of adequate funds. The recommendation is therefore made that the State should order a sufficient appropriation. The report refers to a law of 1900 by which the Legislature established the New York State Hospital for the Treatment of Incipient Pulmonary Tuberculosis, and states that as the site has not been yet selected there is at present no call for action on the part of the board. The report shows that there are 1600 deaf persons being educated at the various schools for the deaf in the State, most of them maintained at State, county, or city expense. During the fiscal year ending Sept. 30th, 1900, the total number of State poor provided for by the Department of State and Alien Poor was 2004 as against 2135 during the previous fiscal year, a decrease of 131. During the fiscal year the department removed 70 alien poor persons to their homes in other countries. The State Board of Charities is doing excellent work at present and has well fulfilled its duties in the past, so that there seems to be no predominating reason why the existing condition of things should be changed. The whole matter is ably set forth in a leading article in the *New York Medical Record* of

Feb. 16th, 1901, and a strong plea is urged against the abolition of the existing board.

Anti-vice Crusade in New York City.

A wave of reform is sweeping through New York. The movement was initiated by clergymen of all denominations, backed by respectable citizens and headed by Bishop Potter. A committee of 15 has been formed to investigate the true condition of affairs and to suggest measures to stamp out or to check the evil. The physicians of New York are now interesting themselves in the matter, and at the meeting of the Medical Society of the County of New York, under the presidency of Dr. George B. Fowler, on Feb. 25th the subject was discussed. The chairman of the committee was present as was the head worker in the University Settlement, both of whom enunciated their views on the situation. Dr. Prince A. Morrow read a paper entitled "The Prophylaxis of Venereal Diseases in New York City: Medical Aspects of the Social Evil." Dr. Morrow first drew attention to the ravages caused in the community by venereal diseases and to the apathy evinced by medical men with regard to their prevalence. He said that at the present day the extermination of every contagious disease was the watchword of modern sanitary science, yet there was not a single city in the United States in which these diseases were subject to sanitary supervision. The arm of the law should be invoked in suppressing low dance halls, in raising the age of consent to 21 years and in meting out the severest punishment to the men and women who made a business of selling human beings into something worse than slavery. Public opinion, which often had a force independent of its merits, forbade the establishment in the United States of the European continental system of restriction. It had been tried in St. Louis for about a year, but had then been swept from the statute books by an avalanche of protest, principally from women and clergy. Dr. Morrow ended an eloquent address by saying that a higher order of education and *morale* among men must be looked to as the best means of diminishing prostitution. The vast majority of fallen women became so fallen not from choice, but because of hard social lines that forced them into the life. Society should deal with them as unfortunates rather than as criminals. Dr. Frederick R. Sturgis, in criticising Dr. Morrow's remarks, took a different stand on the matter. He doubted that syphilis was the fatal disease it was asserted by some to be, and averred if it were that the population of towns would be decimated. He was strongly of the opinion that alcoholism was far more dangerous to health than were venereal diseases. Dr. Sturgis urged that the most effective means of curtailing the spread of syphilis and gonorrhœa would be restrictive measures rigidly carried out. He protested against sufferers from venereal diseases being regarded as martyrs and treated free, and said that the physician who mixed medicines with morals was sure to come to grief; his true function was to show the people where the dangers lay. Dr. Charles W. Allen said that he was convinced that venereal disease was on the increase in New York and that in the first instance steps should be taken to control those people who would go out from the hospital while in the infectious stage of the disease. He also suggested, as he had done 10 years before, that the subject of syphilis should be made so much more public that the general reader might be instructed a little more and might thus be enabled to understand what family syphilis meant to the community. The chairman of the committee of 15 and the head worker in the University Settlement both agreed that the first and most important step forward must be with the medical profession, who must educate the people and so shape public opinion that the efforts of laymen in the same direction would be accepted and appreciated. Sexual vice is rampant in New York, more so probably than ever before, and it is a good sign that influential citizens are beginning to appreciate their responsibility.

Trial of Male Nurses attached to the Bellevue Hospital.

The public outcry against the reported condition of affairs in Bellevue Hospital culminated in three of the male nurses attached to the insane pavilion in that institution being put upon their trial for the murder of an inmate. The patient, a man named Hilliard, died suddenly, and upon a necropsy being performed by the coroner that official declared that his death was caused by injuries, among which was the fracture of the hyoid bone. These injuries were the outcome of violence, and witnesses were forthcoming who testified that they had seen the three nurses use very rough treatment to the deceased lunatic. Other witnesses declared that the man must have received his injuries while in Bellevue Hospital as he was free from bruises when he was admitted. At the trial of one of the nurses the evidence for and against was very conflicting, but finally it was found by the jury that there was not sufficient direct evidence to convict the nurse, and consequently he was acquitted. The verdict upon the whole must be esteemed a just one, the majority of the medical expert witnesses asserting that the dead man's injuries were not severe enough to cause death. At the same time conclusive proof was brought forward to show that unnecessary violence had been used on more than one occasion in the insane pavilion in Bellevue Hospital. Undoubtedly the public showing up of the New York municipal institutions will be productive of nothing but good, as it will pave the way for the introduction of drastic reforms and will be the means possibly of removing them from the control of politicians and placing them in the position which all rightly-managed charitable establishments should occupy. The other two nurses will shortly come on for trial upon the same charge as the one who has just been acquitted, but judging from the result in his case it is only reasonable to suppose that they, too, will be freed.

Mr. Reginald Harrison has been spending a holiday in the United States as the guest of Dr. Frederic S. Dennis, Hon. F.R.C.S. Eng. Mr. Harrison gave an interesting lecture in the new Cornell Medical College building which has been erected through the private munificence of Colonel Payne. The subject of his lecture was "The Prostate, Lithotomy, Renal Tension, and Antiseptics in reference to Genito-Urinary Surgery."

March 20th.

Obituary.

ARTHUR COPPEN JONES.

MR. ARTHUR COPPEN JONES, who was well known as a bacteriologist, died in the thirty-sixth year of his age at Davos Platz, on March 8th. For many years he had made Davos his home. Before his health broke down 15 years ago he had studied comparative anatomy under Huxley. When his health had been partly re-established he took up the study of bacteriology under Koch in Berlin. Later he did a valuable piece of original work on the morphology of the tubercle bacillus. His paper in the *Centralblatt für Bakteriologie* at the beginning of 1895 brought forward evidence that the tubercle bacillus should really be regarded as belonging not to the bacteria but to the moulds. In accordance with this view, and to indicate the resemblance to actinomyces in mode of growth in pure culture, he suggested the name "tuberculomyces" in place of the name in common use. For the last few years Mr. Jones was a great invalid, suffering much. Nevertheless he had the energy to produce the excellent translation of Fischer's book on the "Structure and Function of Bacteria," which appeared a few months ago under the auspices of the Clarendon Press. To old readers in the London Library Mr. Jones's father, the late Mr. J. E. Jones, was a familiar figure. Mr. Jones was an interesting talker and a pleasant companion. He will be greatly missed by the residents of his adopted home.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. J. H. Linsley, formerly Professor of Pathology and Bacteriology in the University of Vermont.—Dr. Dufraigne, formerly Senator for Seine-et-Marne.—Dr. Busey, formerly Professor of Materia Medica in the University of Georgetown, Washington.—Dr. Emil Kammerer, Oberphysicus of Vienna, to whom the city is greatly indebted for its sanitary organisation. He was only 54 years of age.

LITERARY INTELLIGENCE.—Under the title, "A Tour through North Eastern Ireland," Sir John W. Moore, ex-President of the Royal College of Physicians of Ireland, is writing some descriptive papers in the *Leisure Hour* for March and April. Intending tourists in the Emerald Isle should read these chapters by one who, as a prominent medical man, is able to know how well his country is adapted to supply the seeker after health and recreation.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In March the following candidates passed in the subjects indicated :—

Surgery.—W. A. Brown, McGill; P. J. R. Bucknill (Section I.), Manchester and Dublin; R. Gillett (Sections I. and II.), Royal Free Hospital; J. I. Halstead (Section II.), Manchester; J. J. Haverson, London Hospital; W. J. Hogg (Section I.), Belfast; F. P. Joscelyne (Section I.), Leeds; C. A. Lower (Sections I. and II.), Guy's Hospital and Bristol; J. C. McCarroll (Section I.), Belfast and Middlesex Hospital; F. McTavish (Sections I. and II.), Toronto; C. G. Meade (Section II.), St. Bartholomew's Hospital; A. C. Oliver (Sections I. and II.), Charing-cross Hospital; and H. Smith (Section I.), Birmingham.

Medicine.—J. W. Bowd, St. Bartholomew's Hospital; W. A. Brown, McGill; P. C. Burgess (Section I.), Middlesex Hospital; H. P. Fox (Sections I. and II.), London Hospital; F. P. Joscelyne (Section I.), Leeds; J. Kemp (Sections I. and II.), Manchester; B. S. O. Maunsell (Section II.), St. Bartholomew's Hospital; J. C. McCarroll, (Section I.), Belfast and Middlesex Hospital; and W. B. Skelton, Guy's Hospital.

Forensic Medicine.—G. Aldridge, London Hospital; W. A. Brown, McGill; P. J. R. Bucknill, Manchester and Dublin; H. N. Collier, Guy's Hospital; W. P. A. Hardwicke, Durham; A. T. Harvey, London Hospital; D. T. Jones, Middlesex Hospital; F. P. Joscelyne, Leeds; J. Kemp, Manchester; J. C. McCarroll, Belfast and Middlesex Hospital; P. G. Sheppard, Cambridge and Liverpool; W. B Skelton, Guy's Hospital; and C. H. Williams, St. Bartholomew's Hospital.

Midwifery.—J. W. W. Adamson, St. George's Hospital; J. B. Bradley, Birmingham; W. A. Brown, McGill; A. T. Harvey and J. J. Haverson, London Hospital; H. C. Hocken, Cambridge and Westminster Hospital; F. P. Joscelyne, Leeds; F. M. Payne, Royal Free Hospital; W B. Skelton, Guy's Hospital; A. F. Van Dijk, St. Bartholomew's Hospital; and C. M. Woods, Charing-cross Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—G. Aldridge, W. A. Brown, H. P. Fox, F. McTavish, A. C. Oliver, and C. H. Williams.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. August Wasserman has been recognised as *privat-docent* of Hygiene.—*Cracow:* Dr. S. Maziarski has been recognised as *privat-docent* of Histology.—*Göttingen:* Dr. Schiek of Halle has been recognised as *privat-docent* of Ophthalmology.—*Rome:* Dr. Boari has been recognised as *privat-docent* of Surgical Anatomy and Operative Medicine, Dr. Lo Monaco as *privat-docent* of Experimental Physiology, Dr. Jacoangeli as *privat-docent* of Experimental Pharmacology, Dr. Bastianelli as *privat-docent* of Medical Pathology, Dr. Caselli as *privat-docent* of Surgical Pathology, and Dr. Berghinz as *privat-docent* of Pædiatry.—*Würzburg:* Dr. Burckhardt has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Zürich* Dr. Ernst Heuss has been recognised as *privat-docent* of Dermatology.

THE LONDON SCHOOL OF TROPICAL MEDICINE have signalised the successful working of the first 15 months of the school by the issue of a little *brochure* containing a report for the year 1899–1900, together with an account of the origin, progress, aims, and requirements of the school. Among the tropical diseases treated during the period mentioned we notice that there were 55 cases of acute malaria, four cases of chronic malaria, 29 cases of beri-beri, seven cases of guinea-worm, and four cases of plague. In the list of students who have passed through the school since Oct 1st, 1899, will be found the names of nine qualified medical women. At the present time upwards of 120 post-graduate students have passed through the school.

SEASIDE CAMPS FOR WORKING BOYS.—The thirteenth session of this useful organisation will open on Saturday, July 20th, and will close on August 31st. The camp, which was founded in order to give a seaside holiday to London working boys of good character whose means are too small to allow of a real holiday without help, is situated close to the sea and is under the charge of a commandant who while maintaining discipline teaches the boys to enjoy life, to learn about the country and the sea, to play games, and to get health and manliness so that they may return refreshed and strengthened to their work in London. The secretary is prepared to give lantern lectures on the subject on application to him at Northumberland Chambers, Charing-cross. The list of articles which each boy is required to bring with him to the camp does not, we notice, include an important aid to health—the tooth-brush.

INCREASED CHARGE FOR LUNATICS IN LANCASHIRE.—The Chorlton and the Prestwich Boards of Guardians have each received a communication from the Lancashire Asylums Board stating that at the last meeting the board had decided, on and after April 1st, to increase the weekly rate of maintenance for pauper patients received in the board's asylums from unions within the county from 8*s.* 9*d.* to 9*s.* 4*d.* The Chorlton Union has 731 patients in the county asylums, and the increased cost will make the yearly expenditure greater by £1108, and it will make a difference of between £300 and £400 a year to the Prestwich Union.

GENERAL HOSPITAL, BIRMINGHAM.—An influential and representative assembly attended the recent annual meeting at this institution. The annual report, the 112th, stated that there had been an increase of 347 in the number of in-patients and of 258 out-patients; the number of operations had advanced in three years from 1496 to 1702, and in 1900 to 1815. As to the finances during the past year the deficit of upwards of £700 had been reduced to about £1600. Sir J. C. Holder, Bart., intimated his desire to perpetuate the memory of the late Queen Victoria by dedicating a bed in the hospital as an "In Memoriam," an offer which was accepted, and subsequently a cheque for £1250, the amount required, was received from him.

SOCIETY FOR THE PREVENTION AND CURE OF CONSUMPTION IN THE COUNTY OF DURHAM.—A special court of governors of this society was held in the Town Hall, Sunderland, on March 19th, which unanimously sanctioned the expenditure of £1400 on the building of a new wing (to contain a large dining-room, kitchen, bedrooms for eight women, and bathroom for same); on the erection of a verandah on the south side of the main block; on the conversion of one of the present bedrooms into a bathroom for men; and on the conversion of a building into five additional bedrooms. These additions, which will be begun forthwith, will raise the accommodation to 25 beds and will comprise administrative accommodation for 40 patients and leave only 15 beds to be provided later in order to complete the society's scheme for 40 beds at Horn Hall Sanatorium, Stanhope. The chairman, Dr. Robinson, reported that the results obtained at Horn Hall had been as good during the winter as they had been during the previous summer and that they had quite come up to the expectations of the committee.

PRESENTATIONS TO MEDICAL MEN. — On March 8th a deputation representative of the parishes of Borthwick, Carrington, Heriot, Newbattle, Stobhill, and Tample, waited upon Mr. William Spalding, M.D. Edin., M.R.C.S. Eng., of Gorebridge, Edinburgh, at his residence, and presented him with an illuminated address and a cheque for £200 subscribed for by his many friends on his retiring from his public duties and professional activity during the long period of 39 years amongst them.—Mr. E. Sergeant, medical officer of health to the County Council of Lancashire, was the recipient of a presentation on March 22nd, subscribed for by the medical officers of health of the administrative county, on the occasion of his marriage in December last. The presentation was made in the Chemical Club rooms, Victoria Hotel, Manchester, the meeting being presided over by Mr. Chadwick, medical officer of health of Milnrow, who was supported by a number of medical officers of health. Mr. William Berry, medical officer of health of Wigan, made the presentation which consisted of a silver tray, silver fruit-knives and forks, and an album containing the names of the subscribers.—On March 22nd, at a meeting held in the Cottage Hospital, Auckland, of the governors and house committee, Mr. T. A. McCullagh, M.R.C.S. Eng., L.R.C.P. Edin., was the recipient of a testimonial, consisting of a valuable edition of Ruskin's "Stones of Venice," each volume containing an inscription stating that it was presented to him by the governing body and other subscribers as a token of esteem, and in recognition of his valuable services in connexion with the Auckland District Cottage Hospital as secretary and otherwise. At the same time Mrs. McCullagh was presented with a silver coffee-pot.—On the occasion of Dr. F. J. Allan resigning his post as honorary secretary of the London

Galloway Association, increased official duties being the reason of the resignation, the officers and council of the association presented to him with a gold ring and a set of four silver entrée dishes.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—The committee of management of this society has arranged to hold the summer meeting of the society in the Medical Department of the Yorkshire College, Leeds, on Friday, July 5th (3 to 6 P.M.), and Saturday, July 6th (10 A.M. to 12.30 P.M.). The society's dinner will take place on July 5th, at 7 P.M. Dr. Wardrop Griffith is making local preparations for the meeting, and it is desirable that members should as soon as possible intimate to him, at 43, Park-square, Leeds, their intention of being present, so that he may make suitable arrangements for them, as a large meeting is expected.

Mr. Henry George Hawkins Monk, who since 1895 has been medical officer of health of the borough of Leicester, has resigned that appointment for a similar position in Kimberley, South Africa. Mr. Monk went to Leicester from Scarborough, and through his energies many much-needed improvements have been effected in the former town. Three years ago, however, his health gave way, and to this fact is due his acceptance of a colonial appointment. Mr. Monk sails from Southampton in the s.s *Norman* on April 6th, and he will carry with him to South Africa the best wishes of the people of Leicester.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—On March 14th the annual meeting of the subscribers to this hospital was held in the Stephenson Memorial Hall. The report for the past 12 months showed an increase of 48 more patients than in the previous year. The hospital at intervals had been very full and the patients remained for treatment for an average of 36 days. Though the ordinary income amounted to £2147, and the legacies to £533 there was still a deficiency on the year of £1200. The subject of establishing a medical ward was introduced and after some discussion a generous offer of Alderman Eastwood in respect thereto was accepted, provided that adequate funds were forthcoming for its support from the general public.

NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.—The second general meeting of members of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was held at 20, Hanover-square, London, W., on March 25th, the Earl of Derby being in the chair. The chairman, in moving the adoption of the report of the council, said that the second general meeting of the association marked a distinct period in their history. He claimed for the association that it had directed public attention in a marked degree to the necessity of dealing with tuberculosis as an evil to be combated in every shape. The report of the council was a very complete and full one, and in the variety of the subjects mentioned it would be recognised that the association had advanced. They hoped that it was a progress which time would assist. Their financial position was not such as to cause anxiety. The council had arranged for the meeting of the British Congress on Tuberculosis on July 22nd, and he believed that distinguished men of science from the colonies and European countries had freely responded to the invitation to be present. The principle of the early isolation of tuberculous patients had been recognised by public bodies and in some measure had been already carried out in some of the large towns. Steps had been taken in some districts for the notification of phthisis and also for relief, provided that the family arranged for the patient having a separate sleeping-room and taking other simple precautions. The progress of sanatoria was being pushed on, and he was glad to be able to report that the work of the association was going forward, and he hoped it would lead to still greater things. Professor Clifford Allbutt, who seconded the motion, insisted on the importance of securing early treatment in tuberculosis. Sir T. Dyke Acland directed the attention of the executive to the fact that in large agricultural shows there was no regulation to prevent the admission of tuberculous animals. Dr. C. Theodore Williams considered that in regard to unhealthy occupations help should come from the State. The meeting terminated with a vote of thanks to the chairman.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, MARCH 21ST.

Unwholesome Tea.

MR. HENRY HOBHOUSE asked the President of the Local Government Board if his attention had been drawn to the quantities of inferior and unwholesome teas imported into this country which were alleged to contain microbial products dangerous to health; whether the inspectors of the Board had power to seize, analyse, and condemn such teas, and to what extent such powers were exercised; and, if, in the interests of public health, he was willing to institute an inquiry into the best methods of checking the sale of such unwholesome teas by determining some minimum standard of purity and by securing a proper analysis of such teas before they were blended with other teas.—MR. LONG replied: The Local Government Board have no definite information as regards the matters referred to in the first paragraph of the question. Under the Sale of Food and Drugs Act, 1899, the Board may in certain circumstances direct an officer to procure samples of tea for analysis. The result of the analysis is to be communicated to the local authority, and thereupon it becomes the duty of the local authority to cause proceedings to be taken just as if they had caused the analysis to be made. The Public Health Acts contain provisions under which articles of food which appear to be unwholesome or unfit for the food of man can be dealt with by officers of local authorities. I am not at present aware of sufficient reason for any such inquiry as that suggested.

Borax in Food.

MR. LONG, in the course of an answer to a question on this subject, which had special reference to Professor Thorpe's statement at a recent meeting of the Arsenical Poisoning Commission that he had found no borax of commerce free from arsenic, said that if it should appear that mixing borax with any article of food rendered it injurious to health, a person so mixing it with intent that the article may be sold in that state would be liable to proceedings under the existing law.

Vaccination in Poor-law Institutions.

MR. GODDARD asked the President of the Local Government Board whether officials appointed by a board of guardians were or were not under the immediate control of the board of guardians appointing them; and whether the superintendent of a home under the board of guardians could cause the children in such home to be vaccinated independently of the wishes of the parents or of the guardians.—MR. LONG: The duties of the more important officers of a board of guardians are prescribed by statute and by regulations made by the Local Government Board or their predecessors. The regulations generally contain a provision to the effect that the officer is to obey the lawful orders and directions of the guardians applicable to his office. The view of the Board is that under ordinary circumstances a child in an institution such as that referred to in the question should not be vaccinated if the parent or, in the case of an orphan or deserted child, the guardians, object.

Medical Officers of Health and the Diseases of Animals.

MR. FIELD asked the President of the Local Government Board whether any, and if so what, test of knowledge of the diseases of animals was required from candidates before being appointed medical officers of health.—MR. LONG replied: No test of the kind referred to is required by law.

Poor-law Patients and the Franchise.

MR. HENRY J. WILSON asked the President of the Local Government Board (1) whether he was aware that electors were disfranchised if they or members of their family dependent upon them were treated as patients in a workhouse hospital even though the guardians of the poor received full payment from the elector or his friends for the cost of treatment, and that the same disfranchisement took place if, owing to lack of hospital accommodation, the municipality arranged with the guardians for infectious cases for which the municipality was responsible to be treated at the workhouse hospital, and the municipality paid to the guardians the full cost of such treatment; and (2) whether the Government would take steps to prevent such disfranchisement taking place.—MR. LONG: I am not aware that the allegation contained in the first paragraph of the question is correct. I have no authority to determine whether an elector is disfranchised under any of the conditions referred to in the question or to take any steps in the matter, but so far as I am able to form an opinion a person would not be disfranchised in the circumstances stated.

The Holidays of Poor-law Medical Officers in Ireland.

MR. DALY asked the Chief Secretary to the Lord Lieutenant of Ireland whether he had called for the resignation of those officials connected with the Local Government Board who had been compelling boards of guardians in Ireland to give compulsorily four weeks' holidays to medical officers previously to the decision of the Court of King's Bench in this matter; and whether, seeing that this order cost the boards of guardians about £10 000, he would direct a refund.—MR. GEORGE WYNDHAM said that his reply to both questions was in the negative.

FRIDAY, MARCH 22ND.

The Plague at Cape Town.

MR. CHAMBERLAIN, in the course of a reply to a question on this subject, said that to check the plague the Cape Government were doing everything in their power under the advice of Professor Simpson, one of the best experts, and were having six medical men sent out specially for plague duty.

Inspection of Meat for Tuberculosis.

MR. LONG said, in answer to a question, that the Local Government Board had no prescribed regulations for the guidance of medical officers of health and sanitary inspectors with regard to the examination of meat for tuberculosis. The Royal Commission laid down certain principles which, in their opinion, should be observed in the inspection of tuberculous carcasses of cattle, and the Board in March, 1899, drew the

attention of all sanitary authorities to this matter and stated that the authorities should direct those of their officers who were employed as meat inspectors to act in accordance with the principles laid down by the Royal Commission.

SATURDAY, MARCH 23RD.

Case of Plague at Southampton.

Mr. JOHN CAMPBELL asked the President of the Local Government Board if he could give any information as to the reported case of plague at Southampton, and what measures were being taken to prevent the spread of the disease.—Mr. WALTER LONG replied: The case referred to is that of a Lascar who was one of the crew of the *Simla* and came under the consideration of the ship's surgeon when the vessel was two days out from Cape Town. Though regarded with some suspicion the case was deemed not to be one of plague and on arrival at Southampton the man was sent to hospital for the local abscess to be opened. This having been done and matter from the abscess having been bacteriologically examined the case was ascertained to have been one of bubonic plague. The man is now convalescent. An inspector of the Local Government Board has visited Southampton and he reports that all necessary precautions had been taken by way of disinfection and for keeping under observation the various persons with whom the man had been associated during the voyage and afterwards.

TUESDAY, MARCH 26TH.

The London Water Question.

At this sitting there was a long debate on the motion for the second reading of the Bill for the purchase by the London County Council of the undertakings of the eight companies which supply the metropolis with water. The Government opposed the Bill and promised to introduce next year, and endeavour to pass, a Bill based on the recommendations of the Royal Commission presided over by Lord Llandaff. The House threw out the Bill by 253 to 176 votes

WEDNESDAY, MARCH 27TH.

Beer Bill.

By 245 votes to 133 the House decided to give a second reading to the Beer Bill, a measure designed to enable consumers to distinguish between beer made from barley and hops and beer containing other ingredients Sir MICHAEL FOSTER spoke in opposition to the Bill, claiming that it was a retrograde measure and opposed to the march of science. He said that the epidemic in the Manchester district ought to have been foreseen, that if there had been an adequate watch over the materials used for the preparation of food it would have been known that since the South African war had used up all the sulphur the manufacturers of sulphuric acid had been resorting to pyrites. Invert sugar was not cheaper than malt and was used to supplement the alcohol obtained from the malt, and whether glucose was got from cotton waste or from German sawdust the ethylic alcohol was the same. Brewing, he said, was becoming a scientific occupation. Every year it was improving and the tendency was to produce for the consumer a better and more wholesome article at a lower price.

ROYAL COMMISSION ON ARSENICAL POISONING.

FRIDAY, MARCH 15TH.

THE Commission met again to-day with the same attendance as at the previous meeting and with Lord KELVIN presiding.

Mr. E. O. SIMPSON, solicitor, attended on behalf of Messrs. NICHOLSON, chemical manufacturers, Leeds, and intimated to the Commissioners that his clients had prepared a statement for submission to them. He was prepared to hand in the statement now but he asked that its public reading and any examination upon it might be postponed until, if possible, the legal action now pending with Messrs. Bostock had been disposed of.

The CHAIRMAN said that the Commissioners were perfectly willing to accept the statement now and postpone its public reading and examination upon it until a reasonable and suitable time, though they could not give a pledge that the postponement would be until after the decision of the legal action.

Dr. JOHN TATHAM of the Registrar-General's Office, examined by the CHAIRMAN, said that since he had been requested to attend in order to furnish the Commission with such information as could be gleaned from the national death register with respect to the mortality of certain diseases now the subject of inquiry by the Commission, he had had the advantage of perusing the most instructive report on arsenical poisoning submitted to the Local Government Board by Dr. Buchanan and as a result he had been able to see the kind of information that would be useful to the Commission. Up to the present time neuritis had not been separately classified in the Registrar-General's report. Ordinary neuritis was classified under the heading of nervous diseases, arsenical neuritis under arsenical poisoning, and alcoholic neuritis under alcoholism. About the middle of last year in abstracting the details in England and Wales for 1899 they noticed a considerable access of death return under the head of neuritis. It was some two or three months before they in London heard anything of the epidemic of arsenical poisoning in Lancashire. Some of the deaths were returned simply as neuritis, others alcoholic neuritis. When they came to abstract the details for 1900 he made arrangements that the deaths from neuritis should be separately classified in all possible detail, and by the end or shortly after the end of May he hoped to have that process complete. He hoped then to be able to give the Commission the number of deaths directly attributed to poisoning by arsenic, lead, and other mineral poisons, the number of deaths definitely ascribed to alcoholism as well as those frequently found to be associated with it, and the number of deaths ascribed to a combination of any of these causes.

By Sir WILLIAM S. CHURCH: The term neuritis had been very much more used in recent years than formerly. To go back for many years would be a troublesome and expensive process and he feared the result might be misleading.

Evidence of Dr. F. W. Tunnicliffe.

Dr. F. W. TUNNICLIFFE, Professor of Materia Medica and Pharmacology in King's College, London, was the next witness examined. His evidence had reference to his researches in association with Dr. Rosenheim upon selenium compounds as factors in the recent poisoning epidemic. He said that he and Dr. Rosenheim were able to obtain for analyses a sulphuric acid manufactured by Messrs. Nicholson which they had every reason for believing was used in the making of Messrs. Bostock's brewing sugar. This acid contained 0·3 per cent. of selenious acid and a relatively small amount of arsenious acid, 0·3 per cent. They further examined several other commercial sulphuric acids, one of which was said to be implicated in the epidemic. This, however, they doubted. The other acids were obtained in the open market from well-known makers. They all contained selenium in small quantities. One of them was practically free from arsenic. The highest amount of selenium found by them in a sulphuric acid was lower than that found by Drinkwater—namely, 0·4 per cent. in a commercial sulphuric acid examined by him. The results of witness and Dr. Rosenheim with regard to the presence of selenium in the practically arsenic free acids confirmed those of Schlactenhauffen and Pagel. The conclusion of importance to be drawn from these results was that from time to time there apparently cropped up a commercial sulphuric acid containing a dangerous quantity of selenious acid, and this latter might or might not be accompanied by an equally dangerous amount of arsenic. Hence it would seem advisable that sulphuric acid intended for use in the manufacture of food-stuffs should be supervised with regard to selenium as well as with regard to arsenic, especially as there should be no difficulty in freeing sulphuric acid from selenium. It seemed to him that it should be a comparatively easy matter to separate selenium from sulphuric acid.

By Professor THORPE: He only regarded selenium as being a factor, not as being at the bottom of the mischief. He was of opinion that the main cause had been arsenic, but the selenium had played a part—a subsidiary part. It was not the term brown oil of vitriol that awakened their suspicions; they went down the list of impurities in sulphuric acid and they found selenium.

In further examination by the CHAIRMAN Dr. TUNNICLIFFE said that they next examined two sugars; in one (invert) which came to Bostock's and was used in the preparation of the beer implicated in the epidemic they estimated the selenium quantitatively; in the other (glucose) they simply demonstrated the presence of selenium. The invert sugar contained 0·1 selenium pro mille = 0·14 selenious acid, or 1 in 7000. The invert sugar from the same firm contained, according to published analyses, from 0·3 to 0·4 pro mille As_2O_3. In this connexion they made some experiments with regard to the behaviour of selenious acid in solutions of glucose. They found that this substance might be dissolved in sugar solutions to almost any extent, the resulting solution remaining perfectly clear. They made further an extensive series of experiments with regard to the behaviour of yeast in seleniated sugar solutions. They fermented sugar solutions containing selenious acid in quantities varying from 1 in 100,000 to 1 in 50. Generally speaking, the activity of the yeast, as measured by the production of carbonic acid gas, was not influenced by the presence of selenious acid. In the strong solutions, however, from 1 in 50 to 1 in 500, the activity of the yeast underwent a diminution. Even in the case of the 1 in 50 solution fermentation still took place. The only experiment made in this connexion previously was that of Chabrié, who found that no fermentation took place in a 3 per cent. solution of selenious acid. Yeast had the property of reducing some of the selenious acid to selenium and fixing the latter. In strong solutions (from 1 in 50 to 1 in 1000) under these conditions the yeast assumed a red tint, in some cases actually brick red. Even in solutions of 1 in 10,000 it became pinkish red. They estimated the actual quantity fixed by the yeast and found it to be very small. The selenium was not precipitated as such on the surface of the yeast cell, but was distributed in granular form throughout the cell substance. Under the microscope cyanide of potassium might be seen to dissolve completely out the fixed selenium. These observations entirely confirmed the results of Scheuerle upon the action of selenious acid upon bacteria and moulds; their activity (virulence) was not affected, and selenium was deposited throughout the body substance. They were able to demonstrate the presence of, and estimate the quantity of, selenium in two separate samples of beer emanating from the Salford Brewery, identical with that which was actually consumed by the sufferers from beer-poisoning. Sample A contained 6·2 milligrammes per litre = 0·38 grains per gallon (SeO_2). Sample B contained 5·8 milligrammes per litre = 0·36 grains per gallon (SeO_2). They understood from an independent analysis that this beer contained slightly under one grain of arsenic per gallon. These results showed that when an acid contaminated with selenium was used for the manufacture of brewing materials the selenium passed into the final product—namely, the beer; its quantity in this latter depending upon the quantity originally present in the acid. In the case of Nicholson's acid and Bostock's invert it was present in the beer in poisonous quantities. They made no experiments in regard to malt but he would point out that the flue-dust of certain coal and coke contained selenium. The pharmacology of selenium was practically entirely confined to experiments upon animals, but these were so clear and so numerous that the results might be applied with certainty to man In this connexion selenium has been nearly always compared with arsenic. It was a known fact that arsenic produced the same symptoms in animals as it did in man, and they might with certainty assume the same to be true of selenium. Japtha in 1842 took selenium himself and found that even the metal itself produced marked tissue wasting. Rabuteau, in 1869, from experiments upon animals regarded SeO_2 as having the same action and the same toxic power as As_2O_3 Czapek and Weil, in 1893, came to the same conclusion as Rabuteau; they found that 0·003 grammes (pro kilo body weight?) of SeO_2 killed in a few hours dogs, cats, and rabbits. Chabrié arrived at the same result. This observer noticed a symptom in selenious acid poisoning of interest—namely, the fact that it caused greatly increased bronchial secretion (bronchitis). This had often been observed in arsenical poisoning in man and might very likely be due to the contamination of the arsenic with selenium. Both Chabrié and Czapek and Weil concluded that acute poisoning by selenious acid was similar in all respects to acute poisoning by arsenious

acid. The subject was next taken up by Modica, 1897-98. So far as acute poisoning was concerned he entirely confirmed the results of former observers; he, however, made a most important addition to their knowledge of the subject in that he produced chronic poisoning by selenious acid and compared it at the same time with that produced by arsenious acid. He gave animals doses of selenious acid continuously for 40 days. His results were most important with regard to the subject in hand. He showed that selenious acid caused paralysis, wasting, and degeneration of the hair and inflammation of the subcutaneous tissue. He further showed that although in the case of the arsenicated animals he had, in order to produce symptoms, gradually to increase the dose of arsenic given; in the case of the seleniated animals he had to diminish it or the animals would have died. In other words, that whereas the animals became tolerant to arsenic the poisonous action of selenium was cumulative. This author in a further research upon the action of selenious acid upon metabolism showed that the wasting was due, not as it usually was in arsenical poisoning to gastro-enteritis—i.e., to diminished assimilation—but to increased nitrogenous waste (katabolism).

By Sir WILLIAM S. CHURCH: The experiments were made with several species of animals, including cats, dogs, rabbits, and frogs. Selenium had never been looked for as a source of poisoning in man in the past, but no doubt it would be in the future.

In further examination by the CHAIRMAN Dr. TUNNICLIFFE dealt with the application of the presence of selenium compounds in the beer and the pharmacology of this substance to the explanation of the symptoms in the Manchester epidemic. In this connexion he said:—

(*a*) The symptoms which undoubtedly arose from very small doses of arsenic are much more easily explainable when we remember that to the small dose of arsenic consumed a small dose of selenious acid must also be added.

(*b*) The almost entire absence of tolerance to arsenic in the Manchester patients is also probably to be explained by the presence of selenium compounds in that tolerance to this latter poison apparently does not occur.

(*c*) The marked occurrence of wasting in the Manchester patients occurring independently of gastro-enteritis is to be explained by the specific action of selenious acid.

(*d*) The occurrence of symptoms of so-called arsenical poisoning in cases in which the presence of arsenic in the ingesta was not shown and also explainable by selenious acid.

(*e*) The aberrancy of the symptoms of the so-called arsenical poisoning in former epidemics are probably due to the contamination of the arsenic with selenium in varying proportions.

Selenium, Dr. Tunnicliffe added, did not produce gastric symptoms to the same extent as arsenic.

Sir WILLIAM S CHURCH said that he himself had seen several of the patients in Manchester and it did not strike him at the time that wasting was a very leading feature of the cases.

Dr. A. P. Luff Examined.

Dr. ARTHUR PEARSON LUFF, physician in charge of out-patients and lecturer on medical jurisprudence and on public health in St. Mary's Hospital, London, and one of the scientific analysts to the Home Office, gave evidence as to his work in connexion with the expert commission of the Manchester Brewers' Central Association. He said that he saw a large number of the poisoning cases at the Manchester Infirmary, the Crumpsall Infirmary, and the Hope Infirmary. The great majority of these cases were undoubtedly cases of arsenical poisoning, but modified by the diluted form in which the poison had been taken, by the actual amount of arsenic taken, by idiosyncrasy, and probably by the alcohol and other compounds taken in conjunction with the arsenic. In the great majority of cases the illness began with pains and loss of power in the feet, succeeded or preceded by tingling in the soles of the feet and pains in the calves. In nearly all the cases the extreme tenderness of the calves was a very marked feature. A peculiar huskiness of the voice was also present in a large number of the patients. Amongst the common early symptoms were also tingling of and loss of sensation in the feet and hands, followed by loss of power and ataxy, with a peculiar stepping gait. Pigmentation was one of the marked symptoms amongst the dark-complexioned patients, but was only present to a very slight extent among the fair-complexioned individuals. It generally started as an erythema on the upper part of the chest, thence spreading to the face and hands. This erythema was followed by pigmentation, which was especially evident in those regions where pigment normally occurred, but was also frequently present all over the body. In some cases the individual almost resembled a mulatto as regards the colour of the skin, whilst in others the resemblance to a case of Addison's disease was very marked. Of the other skin affections keratosis of the feet and occasionally of the hands and erythromelalgia were met with. The amounts of beer admitted to have been taken varied from two pints to 15 pints per diem, the average being about from four to five pints per diem. In one case only was the amount admitted to be below two pints, and that was the case of a female, aged 42 years, who, although most carefully questioned on the subject, would only admit the consumption of two glasses of beer a day, and of four or five glasses on Saturdays. Her case was one of well-marked peripheral neuritis, together with the characteristic gait, but with an entire absence of either arsenical pigmentation or any arsenical rash. In only five cases out of the 40 had any spirits been taken for some months, and then, according to the statements of the patients, only in small quantities and very occasionally. He was of opinion that the alcohol of spirits was not a factor in the production of the peripheral neuritis of any of the cases under consideration. In his experience the cases of arsenical poisoning at Manchester differed somewhat from the chronic arsenical poisoning with which he had formerly been acquainted, such as that caused by arsenical wallpapers and by the use of long-continued full medicinal doses of arsenic, in the marked character of the pigmentation and of the skin eruptions in so many of the cases. They also differed from cases of subacute arsenical poisoning in the general absence of marked affections of the gastro-intestinal tract. In his opinion the cases should be classed as intermediate between subacute arsenical poisoning and chronic arsenical poisoning as formerly understood. He was also of opinion that most probably the arsenic was taken in such quantities that had the amount been taken in a smaller bulk of fluid subacute arsenical poisoning would probably have resulted, but that being taken in such a large bulk of beer there occurred a rapid absorption of it from the stomach and intestines, and also a rapid elimination of a considerable amount of the arsenic by the kidneys. Another lesson probably taught by the epidemic was that the views hitherto held as to arsenic being a non-accumulative poison would probably have to be modified. Some of the symptoms point to the fact that the arsenic must have accumulated and have been retained in the system for a considerable period of time.

The Commission adjourned to meet again in Manchester on March 25th.

MONDAY, MARCH 25TH.

The Commission met to-day in the Town Hall, Manchester, for the purpose of examining certain local witnesses. Lord Kelvin was not present and the presidential chair was consequently taken by Sir William Hart Dyke, M.P., the other members of the Commission present being Sir William S. Church, Professor Thorpe, and Dr. Whitelegge.

Mr. R. G. H. THOMSON, manager of Threlfall's Brewery Company, Limited, gave an account of the methods of his company in regard to the use of invert sugar and described the precautions they now take to secure the purity of all brewing materials. Until the outbreak of the epidemic, he said, he had never heard of arsenical poisoning through the medium of beer and had never suspected such a thing. It was also news to brewers that malt could be impregnated with arsenic by the fumes from the fuel used in making the malt.

Dr. MILLER, consulting chemist to a number of the local breweries, bore out the statement that it was only since the epidemic that beer had been tested for arsenic, and said that any beer brewed at the present time in this country would show traces of arsenic if the test were made severe enough. With regard to the malt he said that many malts were now perfectly free from arsenic, but there still appeared to be a difficulty in some cases in getting this absolute freedom. He was of opinion that some test should be applied to the coke.

Professor H. B. DIXON of Owens College gave evidence as to the manufacture of sulphuric acid in this country and the quantity of arsenic usually present in the Spanish pyrites from which most of it was made.

Dr. T. N. KELYNACK was examined at some length with regard to the symptoms exhibited by the patients. The poor, he said, suffered most severely and although both men and women were affected the majority of the fatal cases occurred in women. He had no doubt in his mind as to the cause of the outbreak. In no case had he been able to trace the sugar to any other source than the Messrs. Bostock. In his opinion there should be a statutory test applied to all materials used in brewing. He suggested that there should be analytical laboratories established directly under the control of local authorities and subject to systematic inspection by experts acting under the direction of the Local Government Board.

Mr. W. KIRKBY of Owens College gave evidence as to the results of certain analytical work.

The Commission then adjourned.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

SPECIAL GENERAL MEETING OF GOVERNORS AND SUBSCRIBERS.

UNDER the chairmanship of Lord HALSBURY, the Lord High Chancellor, a special general meeting of governors and subscribers was held at the National Hospital for the Paralysed and Epileptic on March 23rd for the purpose of considering, and if approved, of passing motions providing for an independent inquiry into the allegations contained in the statement issued by the medical staff to the governors in June, 1900, as a condition precedent to any reconsideration of the demand of the staff for direct representation upon the Board of Management and also laying down the conditions essential to be observed with reference to such inquiry.

The meeting was held in the out-patient room and there were upwards of 200 governors and subscribers present.

The LORD CHANCELLOR having been called to the chair said: The business which has caused the summoning of this meeting deals with a situation which undoubtedly is most injurious to the hospital but which seems to me, by reason of various conversations with different members both of the medical staff and of the board, to be very nearly approximating to settlement. In taking the chair I wish to profess myself absolutely impartial, but at the same time I do not dissociate myself from my colleagues on the Board, and I will explain how I think these two propositions are reconcilable. I am of opinion that the question which has given rise to the difference among us is one which may very properly be a subject of debate but which need not cause acrimonious discussion. We must all remember, and I am sure I strive to do so, that we are engaged in furthering an object which we all have at heart—the relief of suffering. Speaking not simply as a member of the Board of Management, but as one member of the State, nothing would seem to be more injurious to such an institution as this than a violent controversy between those who have the responsibility of the management and those men of great eminence and skill on the staff whose self-sacrifice and devotion to duty have undoubtedly been of inestimable advantage to those who benefit by this institution. But I decline to look at this meeting as if it were an array of hostile forces. It is rather my hope and belief that it will be conducted in that spirit of conciliation which animates all of us who are desirous of doing what is best for the hospital and for those who receive its benefits. And I am quite sure that if we are actuated by that spirit, and if, remembering that peradventure we are not all absolutely in the right, we make some little allowance for the faults and feelings of others, we shall arrive at a final conclusion of a matter which no one can doubt is most injurious to the interests of the hospital. For my

own part, I regard the question which has given rise to the controversy as one upon which my mind is really open. Although I voted with the Board on the question of representation of the medical staff upon the Board there is no doubt that there has been undoubtedly a statement of facts which, if they are true and if they are not remedied, would prevent me from consenting to be a member of the Board of Management for one day. These matters ought to be decided, and of course it would be perfectly idle to suppose in a meeting of this sort that we should admit the accuracy of allegations and denials without the least opportunity of investigating them. This meeting, I understand, is called together to decide to what extent these matters shall be investigated. So far as I am concerned, as soon as that is decided by the governors I shall be the first to bring forward the other question—viz., that the representation of the medical staff on the Board should be reconsidered. I hope that we shall be able briefly and harmoniously to determine the question now before us.

Mr. G. W. E. RUSSELL: I have been asked by my colleagues on the Board to move the first of the two motions which are, I suppose, in the hands of everyone. I will read the first motion which I have in charge:—

> *That inasmuch as the demand of the medical staff for direct elective representation on the Board of Management has been expressly based upon certain allegations contained in a statement that was issued by the medical staff to the governors in June, 1900, and inasmuch as it would be impossible to test the accuracy of such allegations at a meeting of the governors, it is hereby resolved that an independent inquiry into the accuracy of these allegations ought to precede any reconsideration of the demand of the medical staff.*

The Lord Chancellor has stated with perfect accuracy that this resolution concerns, not the rights and wrongs of the constitutional question whether the medical staff can claim direct elective representation on the Board, but a separate though not unconnected proposition. We are asked in the terms of this resolution to affirm that an independent inquiry into the allegations made in the statement issued to the governors last summer should precede the inquiry into the constitutional question. I am not going, therefore, to re-argue the merits of the question of direct elective representation. Last summer it became my duty to state my views on the subject clearly and there is no need to re-state them. But it is necessary to recapitulate the steps that have brought us to our present position. The demand of the medical staff is an old demand; it began and was formally made, if I am correctly informed, exactly 10 years ago. It was then opposed by the Board and fell for a time into abeyance. Other methods of communication between the Board and the staff were proposed in preference and were more or less steadily acted upon. Under one of these methods the medical staff sent two delegates to meet the Board to discuss medical questions and that is the form of procedure which was in use up till a recent date. In February, 1899, a rather acute controversy arose between the medical staff and the Board, the question at issue being not, as I can conceive, a medical question. Notoriously the expenses of this hospital in working and management have increased very rapidly. It would be carrying me out of my province to discuss this in detail, but the fact is absolutely without doubt. It became necessary to look round and see whether we could not raise the income of the hospital in something like the proportion of the ever-increasing demands made upon it. It occurred—I think I am right in saying this, though on this point I speak subject to the correction of Mr. Rawlings, our indefatigable secretary, who, whatever else he may be, has been a wonderful chancellor of the exchequer—it occurred to him as a good plan of increasing the income to sanction a small payment by such out-patients as were ready and willing to make it for the medicines supplied to them in this place, not for the treatment. That seemed to us on the Board not to be a medical question but one merely of finance and administration, and those are the questions which, if there are any at all, we consider ourselves competent to deal with and which we by our office and in virtue of our position ought to deal with. Therefore, we proceeded to sanction this alteration in our working system and the result is that we make about £800 a year for the hospital, a sum which cannot be regarded as an inconsiderable contribution to our income. It is a clear gain to the hospital. No hardship is inflicted and nobody is forced to pay. I am informed that the better sort of our patients are really eager to make this small acknowledgment of the benefits they have received by paying for their medicine. At any rate, that system of payment was decided upon by the Board, and I am bound frankly to state in opposition to what we knew to be the consensus of opinion of our medical staff. Shortly afterwards there arose a regrettable misunderstanding. The matter was made the subject of discussion and controversy between the medical staff and the Board, the medical staff being at that time represented by two delegates sent to discuss medical matters in the Board room. There was no doubt that our intention was that these two delegates should be present throughout any discussion on the subject which took place. Owing to an unfortunate accident at some adjournment of the discussion the two representative medical delegates were not invited to be present. So that at the very last stage, not at a preliminary stage, the final decision was taken in the absence of the two representatives of the medical staff. The medical staff then declined to continue the system by which they were represented on our Board by two delegates. They said it had broken down and they declined to carry on any continuance of it, thereby producing a deadlock in the official communications between the medical staff as a corporate whole and the Board, though free communication took place between individual members of the staff and the secretary-director of the hospital. The next step in the controversy came upon us as a very great surprise. In a document dated, if I remember right, May, 1900, that was circulated about June 16th, 1900, a communication was sent out to the governors which most of us are familiar with. For the sake of refreshing the memory of my hearers I read the title: "To the Governors of the National Hospital for the Paralysed and Epileptic, Queen-square." It continues, "We, the members of the medical staff, think it our duty to bring before your notice the fact that to our knowledge the administration of the hospital is very unsatisfactory and that the reputation of the institution is in danger of being seriously compromised." The conclusion is, "In closing this brief survey of the present condition of the hospital, which the medical staff feel it their duty to submit to the governors, they call attention to the following conclusions, which have been unanimously agreed to:

1. That to safeguard the interests of the patients and the reputation of the National Hospital by coöperation of the Board of Management and the medical staff it is indispensable that the medical staff be directly represented on the Board of Management.
2. That in view of the impossibility of their continuing the work at the National Hospital under existing conditions the medical staff appeal to the governors to effect this necessary change in the management of the hospital."

That document was circulated to the governors of the hospital without any reference to the Board as such. Of course, those who were members of the Board were also governors and would receive it in the ordinary course; but it did not come before us officially and as a body, and when it did come to our notice as individual governors I confess that its receipt filled us with surprise. The document contains the following allegations: "The first matters on which the medical staff have to report to the governors are those affecting the immediate interests of the patients, as follows:—(1) the diet of the patients; (2) the condition, care, and treatment of the patients; (3) the nursing of the hospital; (4) on the cause of the maladministration of the hospital; (5) details of the manner in which the present administration has prevented coöperation of the medical staff and Board of Management." These last two items, (4) and (5), may now be disregarded. The items of which I am now speaking are those which set forth in very great detail and in very uncompromising terms allegations to the effect that the diet of the patients was wrong in quantity and quality, that their condition and care and treatment were unsatisfactory, and that the nursing of the hospital was not properly and efficiently organised. Now I say if these allegations are borne out by facts every one of us would feel that a very heavy responsibility lay at his own door. It was therefore a very great source of astonishment and regret to find that our medical officers had thought it necessary to commit themselves to statements of so grave a sort—statements which I must remind my hearers would amount to a heavy indictment against the persons having the oversight of the hospital; and I include not only the Board, but of course our very efficient representative, Mr. Burford Rawlings. We none of us knew that any of these complaints had been lodged by anybody, and as far as I was concerned they came to me as absolute novelties. I am not fond of talking about myself in public, but in one sense I am justified in quoting my own experience, because ever since I have had the honour of being connected with the hospital (which I originally joined at the earnest instance of Sir William Gowers), ever I have made it my habit to be in the wards constantly, that I may see as much as I can of the actual state and comfort of the patients. My ears have been always open to complaints and my eyes open to any abuses, if such were visible. I believe on my part that everything was worked as well as it could be in the hospital, the patients were well looked after and thankful for the benefits they had received, and a general tone of contentment reigned supreme. Great was the astonishment of myself and my colleagues when we found that our administration was so faulty as was alleged in the statement of the medical staff to the governors. Mr. Rawlings was equally unaware of any serious cause of complaint. We were, in a word, taken by surprise. We might have thought (I do not lay any stress on this) that it would have been better if our medical friends had made these representations directly to us in the first instance and then, if not satisfied, had reported the matter to the governors; but that was not the course which commended itself to them and they were entirely within their own rights in going to the governors; but when they had done that we were quite within our rights in investigating these allegations of mismanagement on our own account. Supposing the facts were as alleged the guilt must lie on those who were employed and paid by us for their services and upon ourselves for exercising insufficient vigilance in the interests of the patients. We called a sub-committee which sat during the hottest summer weather and investigated the wards and kitchens and every corner and section of the hospital. We examined all the witnesses who were most likely to add anything to our knowledge—sisters, nurses, and servants in succession. We reported that the charges had what I should call no substantial basis; they could only be made good in such small and irregular instances as must always occur, as I imagine, in the food arrangements of a very large institution which is served from one kitchen. When we had made up our minds and reported it was judged to be necessary to summon a meeting of the governors and that was done in August. It was an inconvenient time to us as well as to everybody else. No one would choose August as a suitable date for a public meeting in London, but it was the earliest possible date after the allegations had been made and inquired into, and we thought that we should allow no time to elapse before we put the result of the inquiry before our governors and judges. On that occasion the constitutional question was argued and was decided against the claims of the medical staff. The moment that decision was made known a rather fierce and acrimonious controversy began in the public newspapers. We had then arrived at the silly season when the newspaper people are only too thankful to have a little extra pabulum, and this really small dispute was by journalistic intervention and enterprise magnified and distorted to the very highest degree. Contributions poured in from some correspondents, some of whom I would say with great respect were not absolutely well informed on the facts at issue. With regard to my own part in that controversy it consisted in a reference to my speech made in this room at the August meeting. I then spoke from the material supplied to me by our professional advisers. I stated in referring to the practices of other hospitals in London that the Brompton Consumption Hospital was one of those which did not admit direct medical representation on its Board of Management. As soon as I had stated that a letter appeared in the *Times* from a very highly respected member of the profession, Dr. J. E. Pollock, saying that I was so far misinformed that at Brompton all the medical staff were honorary members of the Committee of Management. On receiving that authoritative contradiction I made haste in the *Times* to express my regret that I had been misinformed. But only the other day it happened that I received from Dr. Pollock himself, in reply to a question which I had put to him, a rather interesting piece of information. It was to this effect, that although at Brompton the members of the medical staff are ex-officio members of the Committee

of Management they are only entitled to speak there but not to vote. That is so extremely a different position from that claimed on behalf of our medical friends here that I think that my original statement made upon the authority of our advisers was not substantially very wide of the mark. I am reminded by Mr. Bower that Dr. Pollock also said that practically they only attended the Committee of Management when medical matters came up for discussion. During the autumn months this controversy raged with some acrimony, and by degrees during our autumn holiday we, most of us, severally came to the conclusion that those who had best right to be concerned in the matter—that is to say, the subscribers to the institution generally—were not entirely satisfied with the result of our domestic inquiry or with the vote taken at the August meeting. We had hoped that that inquiry would meet the case and would have brought the controversy to an end. But when we saw that there was uneasiness in the minds of those who have the interests of the hospital very sincerely at heart we came unanimously to the conclusion that a fresh inquiry should be undertaken into the allegations of mismanagement and that it should be undertaken by some competent external authority. I need hardly assure my hearers, among whom I recognise some old friends, that there was no inclination on our part to shrink from the fullest investigation of what we had done, imperfectly perhaps, but with good will, in the administration of the hospital during so many years. We welcomed the prospect of an inquiry conducted by some person whose occupation and habits of life have accustomed him to the sifting and weighing of evidence. We were not disposed to submit to that inquiry any question except the allegations of mismanagement. But it became evident, from communications which we had with our medical friends and others, that a much greater degree of public satisfaction would be attained if we waived our own opinion and allowed the constitutional question of representation to be included with the question of mismanagement in the scope of the inquiry; and with a view to carry out that twofold inquiry we invited, through the intervention of the Lord Chancellor, the good offices of an ex-judge of the Supreme Court, Sir Ford North; and although Sir Ford North was willing to place his services at our disposal the medical staff, speaking through the Medical Committee, declined to recognise an inquiry conducted by him and appointed by us. They refused to render assistance by appearing and giving evidence, which would be necessary in order to secure a thorough investigation of their charges. In December last, I believe, we yielded and conditionally consented to the inclusion of the constitutional question in the inquiry, only stipulating this much, that whoever should hold the inquiry should be entitled to consider not merely the demand of the medical staff for a particular form of representation—namely, the direct representation of two members on the Board—but also any other form of representation such as might be suggested by the experience of other hospitals or might commend itself to the minds of many of us as a more workable arrangement. Almost at the eleventh hour, hoping still to save anything like a pitched battle, if that be not too strong a phrase, we suggested to the medical staff that they should consider whether any of the alternative forms of representation, some of which my colleague, Mr. Pearman, was responsible for, would be acceptable to the medical staff. But we were told very emphatically and plainly that they would be satisfied with nothing but the one form on which they had set their hearts—namely, the direct election of two representatives to sit on the Board. (Cries of "Time, time.") The cries of "Time" are very apposite, as I have come to an end of what I have to say. The history has now been adequately presented and we have now arrived at a point where I hope a decision will be arrived at with something like practical unanimity. We invite an inquiry into the allegations which we consider still to be unproved and still unwithdrawn, the allegations into the mismanagement of our patients; and we consent to an inquiry into the question of some mode of securing medical representation on the Board. It is the first resolution which we are now asking your judgment upon. It is only a question of precedence. We ask you to affirm in the first resolution that the question of inquiring into these allegations should precede the constitutional question of representation of the medical staff on the Board. The demand for representation was based on the allegations in the original terms of the circular. (Loud cries of "No, no.") We therefore only ask you now to instruct whoever has charge of the conduct of this inquiry to investigate first the allegations of mismanagement. If they turn out to be well founded the constitution of the Board of Management will afford serious consideration to the hospital authorities. If they turn out to be ill founded it will be for the governors to consider whether the gentlemen who are responsible for such accusations can with advantage serve on the administrative body of the hospital. I therefore move the first motion.

Mr. F. C. CAPEL: I shall not detain you more than one minute. I have been asked to second the motion which would have been seconded by Lord Harrowby who unfortunately is ill. After what has been said by the mover of this motion it is unnecessary for me to add any remarks. I therefore second the motion.

Mr. MELVILL GREEN: I intend to move an amendment. I believe that most in the room have a copy of it. The motion before us should be read. It begins by stating that a demand of the medical staff for direct elective representation of two of their number to the Board of Management is based upon allegations issued in 1900 in the month of June—that is to say, it alleges that a demand which has been made for 10 years or more is based upon a paper issued last spring. That is a difficult statement to assent to and I would rather not try. The next statement is that it is impossible to test the accuracy of such allegations at a meeting of the governors. Quite so. It is impossible to ascertain a great many things in public meetings like this and therefore there should be an inquiry both full and complete and, to use the secretary's words, exhaustive. We are asked to pass a motion for an independent inquiry into the accuracy of these allegations and that this ought to precede any reconsideration of the demands of the medical staff. This is a very remarkable motion. It does not say that there is presently to be an inquiry into the demands of the medical staff. It does not even say that there is now to be an inquiry into the accuracy of the allegations. It affirms only this, that the inquiry should be two and not one and that one of these should precede the other—that is, the whole demand made by this motion. I am going to ask you to dissent from this view altogether. I do not want to refer to history because I am of opinion, as you mostly are, that the object of all of us should be to bring about harmony as soon as we can and as readily as we can, and I think that references to history, if they are faithful, are only likely to provoke further irritation. But I must go back as far as August 11th. I was very pleased with a remark which fell from the mover of the motion that the resolution arrived at in this room on August 11th was arrived at in the silly season. I quite agree with that. On August 11th and up to Dec. 10th the attitude of the Board was unmistakeable. The strongest language possible was used by Mr. Russell on August 11th as to the absolute impossibility of having any inquiry into this question of the demand of the medical staff. He refused the demand as strongly as possible, and mine was the only voice that demanded a full and complete inquiry, for I suppose everybody was out of town. (Cries of "We did not know of the meeting.") I daresay you did not. I am going to repeat to-day what I said then—in fact, I do not think that anybody will be able to say anything that has not already been said in the papers. But still it is necessary, after Mr. Russell's speech, to draw the attention of the meeting to the amendment that I have the honour to move. On Dec. 10th, then, and up to that day the Board were as anxious not to refer, as they are now anxious to refer to-day, the domestic management of the hospital by itself to inquiry. On Dec. 10th the Board, not spontaneously, but because their counsel showed them what a false position they had taken up, began to allow the admission of a wider inquiry. They added as a concession—and I think the staff were unwise to regard it as a concession—that the persons to make the inquiry were to be three instead of one. It secures that the umpire listens with attention to his two colleagues and that is all, and therefore I do not think much was gained by that. Those communications have been broken off and it is immaterial to us how or when they were broken off. I think if I was asked to say that either side have acted with uniform wisdom I could not. So long as there was a chance of the committee of inquiry being partial—that is to say, consisting of a man nominated by a member of the Board—so long were they willing to entertain a free inquiry; but directly that chance is over we have the motion of to-day, which Mr. Russell has told us includes an inquiry into the whole subject. Does it? Read it. It does not do anything of the kind. I do not think I need labour the point that it is necessary and essential that the staff and the Board should be in touch with each other. It is essential. We are told a great deal about hospitals which get on very well without the representation of the staff on the Board, but we have not been told of any one hospital where there is representation of the staff on the Board (and there are a great many) that produces any evil result. Why are these hospitals not quoted? The Board have had every opportunity of communicating with other hospitals, and they have not told us of one single instance of that kind. We can only judge for ourselves from our own experience, which in my case is very limited. I served for some years on an infirmary committee—my town does not boast of a hospital. There we have a rule that not only is every member of the staff a member of the committee, but there was a rule that the senior member should take care, when he could not be present himself, that one of his colleagues was present, so that we might never have a meeting without one of the staff being present. A friend of mine wrote to me yesterday and said, "If the experience of over nine years' chairmanship of a hospital committee of which the whole honorary medical staff are members *ex-officio* be of any service to your fellow governors you are at liberty to use it. In my experience their assistance is essential and I should resign the chairmanship of my committee at once if I was deprived of their assistance." I put it in this way, that we governors must either judge of this matter out of our own limited experience or else have an inquiry about it. The Board will not do it. It is nonsense to tell me that their resolution will meet the case. I propose this amendment:—

> "That a full and independent inquiry be at once instituted by the governors into the statement issued by the medical staff in May, 1900";

I do not say only it is desirable, I say it should be at once instituted. My amendment continues:—

> "the facility of intercommunication between the medical staff and the Board; including the demand of the former for direct representation on the Board";

and that surely raises all kinds of representations. I have reason to think I shall be told in a moment that my motion and amendment do not provide for any reference excepting the particular kind of representations that the medical staff have claimed. The wording is quite wide enough. The amendment goes on:—

> "the position, functions, and acts of the secretary-director";

and that is more necessary than anything else, for that position of secretary-director is unknown in the hospitals of this country. We governors do not know what it means, we only see that it is a very dangerous thing. My amendment concludes:—

> "and the constitution, rules, and management of the hospital generally."

The rules are framed with the effect that the governors are hampered on every hand from governing. We have not heard any reason why the inquiry should not comprehend everything I propose. If the state of the case be as I say the whole thing is one question, and what need is there of cutting the inquiry into two parts? It is suggested that the staff would be satisfied if they were put on the Board without any inquiry into the other things. I do not know whether they would or not. (Loud cries of "No, no.") So much the better. I know that these things would never have arisen if the staff had been represented on the Board. The Board does not understand the sort of influence that two men or even one man—members of the medical staff—would exercise on the Board. The Board themselves, being human, would be instructed by the presence of two medical men, just as the two medical men would be instructed in business matters by the Board. The Board throughout have never spoken of the influence of two members of the medical staff, but always of domination. They keep on saying that, as if the presence

of two medical men on the Board would mean the domination of the medical element over the lay element. Really the policy of fear which characterises this Board is a marvel to me. The Board is afraid of this inquiry. (Cries of "No, no.") Yes, you are. You are frightened of this inquiry. They are afraid of being dominated over by two men, but the charge is that they are dominated over by one man. Their own consciousness that they will yield to two is proof that they yield to one. Now we come to my actual proposal that there should be instituted an inquiry. The manner of the institution is left by my amendment exactly as it is by Mr. Russell's motions to be dealt with by subsequent motions to be carried out. If you carry my amendment you determine that there shall be an inquiry on as wide terms as it is possible to frame and I should wish the inquiry to be made as full and free as it can be. But my whole conception of a committee of inquiry differs from the conception of the Board. They want a sort of tribunal that will deal with the matter as if it were a lawsuit with a verdict for one side or the other. I do not. I want some people who will advise us, though the responsibility rests on the governors. The circumstance that for over 30 years we have never come forward does not in the least diminish our responsibility when such a question as this arises. We are bound to accept the responsibility in consequence of being governors. We cannot discharge that responsibility well unless we have a full and perfect inquiry and a complete report; that is why I want an inquiry so that we can see what ought to be done for the benefit of the hospital.

Sir JAMES CRICHTON BROWNE: I beg to second the amending motion, and in doing so I should say that the court of inquiry into the allegations as to the management or mismanagement of this hospital which is proposed in the motion submitted to us seems to me to have become a matter of secondary importance and a mere by-issue. For what the governors have now to decide is the fate and the very existence of this hospital which has hitherto played so great a part in beneficence and usefulness, and which, thanks to the labours of its medical staff, has attained world-wide renown. It is nonsense to talk about holy-stoning the deck when the ship is sinking, and the lame and partial inquiry which is now proposed to us ought not for one moment to divert our attention from the very vital question in connexion with this institution, and that is the representation of the medical staff upon the Board of Management. In these motions which have been circulated, and which we are now asked to adopt, it is stated that the demand of the medical staff for representation on the Board is expressly based upon certain allegations which are to be submitted to inquiry. That statement is entirely, I am afraid I must say deliberately, erroneous, for it must have been known to whoever prepared this resolution, as it is known to Mr. Russell, that the demand for representation has been persistently urged by the medical staff for 10 years before these things happened, and that the allegations were brought forward not as the foundation of that claim but as illustrations of the fruits—the inevitable fruits—of the present mode of management. The trivial and petty annoyances, the little indignities, the grave obstructions with which the members of the medical staff have, I understand, had to put up with for a long period of years, have culminated, as the staff have from the beginning foreseen that they would, in evils injuriously affecting this institution, and what we as governors have to do is to go to the root of the matter, to effect a reform which will at once put an end to those evils and to the cause and source from which they have proceeded. We must see that any inquiry instituted shall be thorough, searching, and conclusive. If we were to accept and pass this motion and authorise a preliminary inquiry we should not, when that inquiry was finished, be any further advanced than we are to-day. We should have wasted time and the funds of the hospital, and the really burning question—viz., the representation of the medical staff—would still remain to be decided. And remembering as I do that the Board of Management have said in print more than once that that representation shall have their unyielding opposition, I cannot but conclude that the inquiry that is proposed to us is somewhat evasive and illusory and is only calculated to cause delay or perhaps to get rid of the medical staff by a side issue. I have had the curiosity to examine for myself that statement of the medical staff to which reference has been made, the statement of June, 1900, and what I cannot understand is why that report was not at once submitted to the judgment of the governors to whom it was addressed. The Board of Management, without any reference to the governors to whom that report was addressed, dealt with it themselves and appointed three of their own number to inquire, not into the whole indictment brought against them, but only into two selected points in the indictment. And after that inquiry at which their accusers the medical staff were not represented and of which no minutes of evidence had been published,—after that inquiry they called the governors together by an irregularly summoned meeting in the height of the holiday season to ratify their own acquittal of themselves. We have to see that there shall be no repetition of a proceeding of that sort. If there is to be an inquiry it must be thorough and searching and complete and impartially conducted. It must deal with, not only certain allegations, but with all the allegations that have been made by the medical staff. The report or statement of the staff must be the subject matter of this inquiry whenever it is held, and all these allegations must be most diligently inquired into. I am much mistaken if the governors will consent to any limited reference, to any small inquiry. They will insist that all these allegations, including those having reference to the constitution and to the administration of the hospital, shall be inquired into. I would point out that the allegations of the staff were not, as has been suggested to-day, limited to the question of diet or nursing or the condition of the patients, but they included complaints as to the anomalous position and powers of the secretary-director, as to the abuses of the out-patient department, as to the exaction of moneys from patients attending this charity, as to deficient accommodation for the nurses, as to the gradual effacement of the medical staff so that they have been, although they are honorary officers, deprived of their vote as subscribers to the hospital, and as to the rules and various other matters. The medical staff, I am sure, do not shrink from the inquiry. They are prepared to establish every statement that they have made, but they decline to have their professional status in this hospital postponed till after a preliminary inquiry as to draw-sheets and the boiling of potatoes. They say, and I think openly and wisely, "We cannot any longer acquiesce in the present state of things in the interests of this hospital of which we are so proud. In the interests of the patients to whom it is our duty and privilege to minister, and in the interests of our high responsibility, we demand a full and searching inquiry. We desire access to the Board of Management. We have asked from you the very small representation of two out of 12, and we feel sure that if that request of two be granted all need for inquiries will disappear and all dissensions will cease. But we challenge an immediate decision. For years past we have been pressing our views upon the management. We have tried all sorts of suggestions which they have suggested and which have ended in failures, and now we challenge an immediate decision. But that is in the hands of the governors, and by their judgment fairly and honestly ascertained we shall abide. If they accept our proposals we shall zealously exert ourselves as before for the welfare of the hospital. If they reject them and determine that the affairs of the hospital are to be placed unreservedly in the hands of the secretary-director then we shall accept their verdict and retire from the field." The medical staff for some time past have made the position perfectly clear. They have uttered no threats, but they have pointed out what seems to be the inevitable consequence of the line of conduct which is pursued by the secretary-director, and in looking over the correspondence that has taken place I am impressed with the belief (I trust I am doing him no injustice) that the secretary-director has been quietly working for the resignation of the medical staff. (Cries of "No, no.") At any rate, in that tortuous, curious document, with its copious rubric, that has been circulated lately, he contemplates the resignation of the medical staff with great complacency. He says, "The hospital may encounter worse evils than the resignation of the staff." I differ from him. The resignation of your staff in this hospital must mean irretrievable ruin. Remember that you have upon your staff 18 of the most eminent physicians and surgeons in London, men whose names are known and respected wherever medical science is cultivated, whose special skill is of incalculable value to the suffering poor. These 18 physicians and surgeons are unanimous and solid upon this question. If you lose them you will not replace them. Mr. Rawlings perhaps calculates that there are in all professions blacklegs. Let me tell him that the medical profession is unanimous. Our leaders, our journals, have submitted with no uncertain voice that if your staff resign there are no medical men who will consent to the humiliation and ignominy of stepping into their vacant place—at least, no medical men whom it would be good to entrust with the life of a sick cat. I am not going to insult your intelligence by repeating to you the arguments in favour of medical representation on the hospital board. The hospital is a medical institution and every detail of management must be ordered in accordance with the medical instructions and requirements. It will be just as reasonable to deprive the Board of Admiralty of its Sea Lords and to leave the navy entirely in the hands of civilians as to leave a hospital board of management without medical aid and advice. I do not know whether Mr. Rawlings is prepared to assume the command of the *Majestic*, but—I say it with all due respect—that he is just as equal to that command as to the direction of the National Hospital for the Paralysed and Epileptic without medical assistance. Admirable in the performance of his own duties as secretary—I am quite sure that every member of the staff will bestow unstinted praise on him in that capacity—in an evil hour he climbed to the directorate, hence the confusion that has resulted. Our *Majestic* is on the shoals. Every hospital board in this country avails itself in one way or other of medical assistance. The methods by which each does so vary in different cases. Where the medical staff is paid, as in certain old London hospitals, one method is adopted; where they are honorary officers other methods are used. But in all of them medical assistance and advice are obtained in some way, save this National Hospital in Queen-square, in which it appears to be tabooed. And it is just in this National Hospital in Queen-square that medical assistance and advice are so necessary, considering the obscure nature of the diseases dealt with and the technical character of the treatment to be carried out. Mr. Rawlings has insinuated that the exclusion of the medical staff from the Board of Management in this hospital is necessary to prevent the hospital from being overawed and prostituted to experimental practices, from being converted into a scientific workshop and laboratory, and he has tried to wriggle out of that accusation, but his words admit of no other interpretation and they have been correctly understood by Mr. Stephen Coleridge. Well, gentlemen, I am not surprised at the storm of indignation with which the medical staff have received that shameful appeal to vulgar ignorance and prejudice. Every hospital, every sick room, in this country is the scene of experimental practices. The administration of every dose of medicine is an experiment, and it is fervently to be hoped that the medical staff of this hospital, as long as there is one, will continue, in accordance with one of the great objects of the charity set forth in its charter in the very first page, to investigate and study the diseases of the nervous system and to increase our knowledge of these to the inestimable benefit of mankind. But to suggest that the medical staff desire to have representation on the Board in order to convert this hospital into a scientific workshop and laboratory in which mere knowledge will be sought with a callous disregard to the sufferings and lives of the poor is what we may call "striking below the belt." Mr. Rawlings does not allege that anything of this kind has occurred. He is apprehensive that it may happen, and so medical representatives are to be excluded from the Board. I suppose it is possible that at some future time some lay officer in the business department may misappropriate the funds; therefore men of business must be excluded from the Board of Management. The reasoning is absolutely parallel. Let me say to Mr. Rawlings that his humane apprehension constitutes the very strongest reason that has yet been advanced for the immediate election of medical representatives on this Board, for it is absolutely impossible for the Board as at present constituted to judge of the appropriate mode of any treatment or procedure that may be called in question. Picture to yourselves the Board as at present constituted called upon to decide as to the propriety of a dose of methyl-ethyl-chloro-benzine, as to the warrantability of removing a tumour from the ascending parietal gyrus of the Rolandic area, as to the responsibility of the nurses for a bedsore in a case in which they have no knowledge of Charcot's researches and teaching. I could mention numerous instances like this of questions that would come before the Board. There is one case I will quote in which they have already gone astray for the want of medical assistance. Some time ago the Board decided that a small charge should be made to out-patients in this hospital for medicine when in the opinion of the officials they were able to pay it. I think that an objectionable arrangement and a misapplication of the

funds of the institution, which was not intended for patients able to pay. By adopting this system of selling medicines the hospital Board have brought the hospital within the provisions of the Pharmacy Act. A large number of medicines sold here contain arsenic, strychnine, atropine, and corrosive sublimate, and other drugs scheduled as poisons in the Pharmacy Acts, and the statutory regulation of the Act for the Sale of Poisons is that the ingredients of the medicine, together with the name of the person to whom it is sold or delivered, shall be entered in a book kept for that purpose, and the name and address of the seller shall be added to the same. Has that regulation been complied with in this hospital? I hear on most excellent authority that it has not, in which case the Board of Management have made themselves responsible for a long series of breaches of the Pharmacy Act. Could there be anything more ludicrous or conclusive as to the unsatisfactory nature of the present system than the fact that the Board of Management of this hospital has rendered itself liable to be summoned for breaches of the Pharmacy Act? I think not. I have great pleasure in seconding the motion that has been moved by Mr. Melvill Green.

A GOVERNOR: I want to ask if the circular sent out by the Board of the hospital has been sent to governors whose names appear as initials only, because it is not fair if they have not been sent?

Mr. BOWER: Some time ago the medical staff were informed that although it was impossible to give them the addresses of governors who desired to remain anonymous, yet any communication which the staff wished to address to those governors would be duly forwarded. In June, 1900, when the staff issued their statement to the governors, all the copies which were intended for governors who are represented in the list of donors by initials were forwarded by the Board to their respective destinations. Now I have been anxious to intervene in this discussion for some minutes. I have the privilege of not only being a governor of this hospital but of having acted as solicitor to the Board and assisted the Board in the conduct of this great controversy. I wish to explain in one word—and I shall testify my explanation in a manner beyond doubt before I sit down—that this first motion and the other motions to be proposed by the Board to-day are not designed to limit the inquiry, but are designed to lead to a full and absolute inquiry into all matters, including the important one of representation of the staff. In January last the Board passed resolutions providing for the most ample inquiry. These resolutions were communicated by me to the medical staff and as to the greater portion of our resolutions they were accepted by the staff. So that the position of matters was this, that we have come to an agreement with the staff as to the following points of reference that the inquiry was to include (I am now reading from a copy of the staff's resolutions): all the charges made by the staff in their statements, the question of intercommunication between the staff and the Board, the question of past administration of the hospital, the position, functions, and acts of the secretary-director, the existing rules and by-laws so far as any member of the Commission might deem necessary, the inspection of all books and documents as might be desired by any member of the Commission, and the demand of the staff for direct representation on the Board of Management. But then new difficulties arose. One was the intimation of the staff that they would resign if they did not get all that they demanded; the next was that we unfortunately differed from them as to the exact form of tribunal and the mode in which these matters should be referred and the mode which the inquiry was to be in. Now after careful consideration I advised the Board that it would not be practicable to put before a meeting of governors the motions providing in detail for everything that was to be done. We had agreed with the staff up to a certain point and these motions are moved and simply deal with the disputed point. They were designed to lead to a full and complete inquiry. I now am authorised by the mover of the Board's motion, by the seconder, and the Board to say that I have intimated to Mr. Melvill Green that the Board are prepared to accept his amendment. I have been deputed to do this because it was felt right that some explanation should be again made of the policy of the Board which was intended to be carried out by these resolutions.

The amendment was then put as a substantive motion and carried unanimously.

Mr. MELVILL GREEN: I hope the governors will remain to pass the resolutions for securing the impartiality of the inquiry. It is necessary that, the governors having determined that an inquiry shall be instituted, we shall arrive at a body of inquirers who will command the confidence of everybody. If anybody objects to anything, that will be a reason, in my mind, for adopting some other plan to which nobody could take objection. We want the inquiry to result in a report in which we shall all have confidence. It has been suggested that a committee of governors and subscribers (other than members of the Board or medical staff) be deputed to make all necessary arrangements for the constitution of a committee of inquiry. The details, as has been said by Mr. Bower, are probably too numerous to deal with here. It has been suggested that if we appoint a committee of ourselves to make such arrangements we should be taking the most practical course. That would be followed by something of this sort. The committee so appointed will be instructed to place on the committee of inquiry at least one physician or surgeon, one eminent lawyer, one man engaged in commercial or financial pursuits, one man experienced in hospital management, and one other person. That makes five of all sorts and conditions of men. That will be followed by some proposal of this sort: "To empower the committee of inquiry to conduct the inquiry as they may think fit, authorising them to request the Board and staff to employ counsel if the committee of inquiry think necessary, and to provide that all necessary and proper expenses of the inquiry be borne by the hospital funds." But I am now moving only the first of these three consequential directions.

Mr. J. PEARMAN: I was deputed to propose the second of the Board's motions upon the card to-day, but the course which has been adopted and which I am far from finding fault with will render that altogether unnecessary. I was afraid that it appeared that the mover of the amendment, Mr. Melvill Green, was extremely angry with the Board of Management, and I think unnecessarily so, if you will allow me to say so. He was not aware at the time he cast so many aspersions on the Board of Management that at their meeting which was held a few minutes before this it was almost unanimously agreed by the Board that they would accept his amendment.

Mr. MELVILL GREEN: I had no idea of it.

Mr. PEARMAN: I hope that being the case the governors and the whole of the medical staff particularly will believe that the Board of Management have no desire or intention to burke inquiry in this matter. Nothing could be further from their thoughts, and if there was one thing which was nearer their hearts than another it was that there should be a thorough inquiry into the charges made by the medical staff, which were made, I am sure, by them with a full belief on their part that they were justified in making them. At the same time I cannot help believing, having sat on the committee of inquiry which was instituted by the Board, that those charges will, on investigation, be proved upon the whole to be substantially very much exaggerated. So far from the Board having views of their own as to reducing the scope of this inquiry they are in full agreement with Mr. Melvill Green. I have much pleasure in seconding that amendment which has been proposed by Mr. Melvill Green.

Mr. J. WIGAN: I think we are all agreed that the decision of to-day's meeting is of vital importance to this hospital. I have been a governor for nearly 40 years and I am a governor of St. George's Hospital and of other hospitals, and in all these there is medical representation, and I must repeat that we have done wisely in coming to-day to the decision that we have. The only question is that the form in which this is put before the governors shall be done in such a way as to be perfectly explicit. I think with reference to a remark made by a governor just now that every A, B, or C, D, shall also have the report who is not present and every initial shall also have the same document sent to him.

The motion was then put to the meeting and carried unanimously.

Sir HENRY BURDETT: Who are to be on the committee? I propose that Mr. Jonathan Hutchinson be one of them, the Earl of Dudley another, and that Mr. Melvill Green be a third. I see a number of ladies present and the hospital owes much to ladies, so I suggest that it would be a good thing that Mrs. Pearman be another. I would suggest that finance should be represented by a wealthy man who is also a governor. I refer to one who takes an enormous interest in the hospital—Mr. H. L. Bischoffsheim. He will serve, and I have ascertained that Mr. Hutchinson will serve.

Mr. MELVILL GREEN: I was going to suggest Sir Henry Burdett himself, Mr. A. Royle, Mr. J. Wigan, and Sir James Crichton Browne.

Sir JAMES CRICHTON BROWNE and Sir HENRY BURDETT expressed themselves unable to serve.

The CHAIRMAN: I think if the names are not accepted by the meeting *en bloc* they must be put up one by one and the vote must be taken for each in turn. I am only suggesting it because it is the ordinary mode of procedure and Mr. Melvill Green in the ordinary course is the proper person to suggest the names.

Mr. MELVILL GREEN: The list proposed is: Mr. A. Royle, Mr. J. Wigan, Mr. Jonathan Hutchinson, Sir James Crichton Browne, and Mr. Melvill Green. It has been pointed out that the names I have read include those of three medical men which must be balanced probably by others. I believe Mr Wigan has not the honour of being a doctor, but the others, excepting myself are medical men. I am unable to suggest any other persons and really do not know the governors.

The choice of the committee led to a desultory conversation, the following names being finally chosen:—Mr. Jonathan Hutchison, Mr. H. L. Bischoffsheim, Mr. A. K. Hichens, Mr. Melvill Green, Sir John R. Paget, Miss Agnes Kevser, and Mr. J. Wigan.

The instruction to this committee in their choice of a committee of inquiry was finally settled as follows:—

> "To place on such committee of inquiry at least one physician or surgeon, one eminent lawyer, one man engaged in commercial or financial pursuits, one man not a medical man experienced in hospital management, and one other person, none being members of the Board or medical staff."

It was unanimously decided to leave to the discretion of the committee how far counsel should be employed in the inquiry, and it was agreed to pass no motion requiring the printing of the evidence taken.

The proceedings terminated with a vote of thanks to the Lord Chancellor for his excellent services as chairman.

BOOKS, ETC., RECEIVED.

ALLEN, GEORGE, Charing Cross-road, London.

The Literary Year-Book and Bookman's Directory, 1901. By Herbert Morrah. Price 3*s.* 6*d.* net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BOND, FRANCIS THOMAS, M.D. Lond., M.R.C.S., F.R.S. Edin., has been re-appointed Medical Officer of Health by the Cirencester Rural District Council.

CLOWES, ERNEST FRANCIS, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Wotton-under-Edge District of the Dursley Union, vice B Simmons, resigned.

CROOKSHANK, F. GRAHAM, M.D. Lond., has been appointed Medical Officer of Health for the Urban District of Barnes.

GARDEN, H. W., M.B., Ch.B. Aberd., has been appointed Medical Officer to the Tati Concessions, Limited, Francistown, Rhodesia, South Africa.

GRAY, J. P. W., F.R.C.S. Eng., has been re-appointed Honorary Surgeon to the Nottingham and Notts Hospital for Diseases of the Throat, Ear, and Nose.

HERRICK, R. W., M.D., B.Ch. Dub., been re-appointed Honorary Surgeon to the Nottingham and Notts Hospital for Diseases of the Throat, Ear, and Nose.

KEIR, WILLIAM INGRAM, F.R.C.S. Edin., L.R.C.P. Edin., has been re-appointed Medical Officer of Health for the Melksham (Wilts) Rural District.

MCELNEY, ELIZABETH, M.B., Ch.B Edin., has been appointed House Surgeon to the Tiverton Infirmary.

SMYTH, HENRY JAMES, L.R.C.P., M.R.C.S., has been re-appointed Medical Officer for the West Buckland District by the South Molton (Devon) Board of Guardians.

STEWART, DONALD, M.D. Glasg., L.R.C.S. Edin., has been re-appointed Honorary Consulting Surgeon to the Nottingham and Notts Hospital for Diseases of the Throat, Ear, and Nose.

THRESH, J. C., D.Sc. Lond., M.D. Vict., D.P.H. Camb., has been appointed Medical Officer for the Rural District Council's Isolation Hospital, Chelmsford.

WATERHOUSE, RUPERT, M.B. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to the Royal United Hospital, Bath, vice F. C. Forster, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BEDFORD COUNTY HOSPITAL.—Senior House Surgeon. Salary £100 a year, with apartments, board, and washing.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House Surgeon. Salary £60 per annum, with board and attendance.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Surgical Officer. Salary £60 per annum, with board, washing, and attendance.

BOROUGH HOSPITAL, Birkenhead.—Three Honorary Assistant Medical Officers.

BOROUGH HOSPITAL, Bootle.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.

BOROUGH OF LEICESTER.—Medical Officer of Health and Public Analyst. Salary £500 per annum.

BRADFORD POOR-LAW UNION.—Junior Resident Assistant Medical Officer for Hospital and Workhouse. Salary £100, with rations, apartments, and washing.

BRIGHTON THROAT AND EAR HOSPITAL, Queen's-road.—Non-resident House Surgeon for six months, renewable. Salary at the rate of £75 per annum.

CITY DISPENSARY, 29 and 30, College-street, Dowgate-hill, E.C.—Physician.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Pathologist. Salary 100 guineas per annum.

DOVER HOSPITAL.—House Surgeon, unmarried. Salary £100 a year, increasing, with board, lodging, and washing.

FRENCH HOSPITAL AND DISPENSARY, 172, Shaftesbury-avenue, W.C.—Resident Medical Officer, speaking French, unmarried. Salary £80 a year, with full board.

GLAMORGAN COUNTY ASYLUM.—Junior Medical Officer, unmarried, not over thirty. Salary £150, with board, lodging, washing, and attendance.

GOVAN DISTRICT ASYLUM, Crookston, near Paisley, N.B.—Senior Assistant Medical Officer. Salary to begin at £150 a year, with rooms, board, laundry, and attendance.

HAMPSTEAD HOSPITAL.—Resident Medical Officer for six months, eligible for re-election. Salary at the rate of £120 per annum, with rooms, coals, and gas.

HULL ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £60, with board and lodging.

HYDROPATHIC ESTABLISHMENT, Limpley Stoke, near Bath.—Resident Physician.

JESSOP HOSPITAL FOR WOMEN, Sheffield.—House Surgeon, unmarried. Salary £75 per annum, with board, lodging, and washing.

LIVERPOOL HOSPITAL FOR CONSUMPTION.—Resident Medical Officer for new Sanatorium. Salary £300 per annum, with board and apartments.

LONDON OPEN-AIR SANATORIUM, Pinewood, near Bracknell, Berkshire.—Resident Physician, unmarried. Salary £200, with furnished apartments, board, attendance, and washing.

MANCHESTER ROYAL INFIRMARY.—Resident Surgical Officer, unmarried. Salary £150 per annum, with board and residence.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Ophthalmic Surgeon.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer. Salary £60 per annum, with board, attendance, and washing. For six months, eligible for re-election as senior.

NATIONAL DENTAL HOSPITAL, Great Portland-street, W.—Anæsthetist.

NATIONAL SANATORIUM FOR CONSUMPTION AND DISEASES OF THE CHEST, Bournemouth.—Resident Medical Officer, from April 17th to June 30th. Honorarium for the term £50, with board, residence, and washing (no alcohol).

NEWCASTLE-ON-TYNE DISPENSARY.—Two Visiting Medical Assistants. Salary £160 for the first year, and £180 afterwards.

NORTH LONDON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Fitzroy-square, W.—Clinical Assistant for six months. Honorarium at the rate of £35 per annum.

ROCHESTER HOUSE, Little Ealing, W. (under the Metropolitan Asylums Board).—Visiting Medical Attendant. Salary £100 per annum.

ROTHERHAM HOSPITAL.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £85, increasing by £10 a year, with board (excluding stimulants), and apartments.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—House Physician for six months. Salary at rate of £60 per annum, with furnished apartments, board, and washing.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Senior House Surgeon. Salary £75, with board and residence.

ROYAL SEA BATHING HOSPITAL, Margate.—Assistant Resident Surgeon. Salary £60 per annum, with board and residence.

SCARBOROUGH HOSPITAL.—Assistant House Surgeon for three months. Salary £75, with residence, board, and washing; if approved, to be Senior for twelve months. Salary £90, with residence, board, and washing.

SEAMEN'S HOSPITAL SOCIETY ("DREADNOUGHT"), Greenwich, S.E.—House Surgeon. Salary £50 per annum, with board, residence, and washing.

ST. BARTHOLOMEW'S HOSPITAL, Rochester.—Assistant House Surgeon. The salary is £100 per annum, payable quarterly, with board, residence, washing, firing, and light.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary at rate of £24 per annum, with board, washing, and residence.

SUFFOLK GENERAL HOSPITAL.—House Surgeon. Salary £100 a year, with board, lodging, and washing.

THE CHIEF INSPECTOR OF FACTORIES gives notice of vacancies as Certifying Surgeons under the Factory Acts at Wotton-under-Edge in the county of Gloucester, at Petersfield in the county of Southampton, and at Fethard in the county of Tipperary.

UNIVERSITY OF GLASGOW.—Two Examiners in Medicine.

VICTORIA HOSPITAL, Folkestone.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon, eligible for election to the post of Senior. Salary as Junior £75 per annum, as Senior £100, with board, residence, &c.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Assistant Surgeon.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Assistant House Physician for six months. Honorarium at rate of £75 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

AYRES.—On March 22nd, at Talbot House, Brierly Hill, Staffs, the wife of William Ayres, B.A., M.D., of a daughter.

BAXENDELL.—On March 19th, at Hale-road, Bowdon, Cheshire, the wife of Arthur Baxendell, M.R.C.S., L.S.A., of a daughter.

BALFOUR.—On March 25th, at Chard, Somerset, the wife of Tom Stevenson Balfour, M.D., of a son.

BINDLOSS.—On March 22nd, at Harrow, the wife of A. H. Bindloss, M.B., B.C. Camb., of a daughter.

PEARSON.—On March 19th, at Edgbaston, Birmingham, the wife of J. B. Pearson, M.B., C.M., late of Knottingley, of a daughter.

SCOTT.—On March 13th, at Poole-road, Bournemouth, the wife of Bernard Scott, M.R.C.S., of a son.

TRACEY.—On March 24th, at Willand, Cullompton, Devon, the wife of H. Eugene Tracey, M.B., of a daughter.

WORTHINGTON.—On March 21st, at Chesterfield, the wife of Sidney Worthington, M.D., F.R.C.S., of a son.

MARRIAGES.

LAWSON-HANNAM.—On March 20th, at St. John's Church, Buckhurst-hill, Essex, Frank Howard Lawson, M.R.C.S., L.R.C.P., of Steyning, to Katherine Mabel Edith, second daughter of the late George W. Hannam, of Ellerslie, Leytonstone.

THORNE THORNE—SINGLETON.—On March 21st, at Christ Church, Lancaster-gate, W., Leslie Thorne Thorne, M.D., of Inverness terrace, W., to Marcella Mildred, second daughter of Edward Singleton, of Teignmouth.

DEATHS.

JOHNSTON.—On March 23rd, James Crosse Johnston, Brigade-Surgeon A.M.S.

SKENE.—On the 24th inst, at Buckley, Flintshire, William Skene, M.D. Glasgow, F.F.P.S.G., L.R.C.S.E., in his 56th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

JOHANN HEINRICH COHAUSEN.

IN recent numbers of the *Archives Générales de Médecine* some 40 pages have been devoted to an account of the life and writings of Johann Heinrich Cohausen, a Westphalian medical man and miscellaneous writer who made for himself a considerable reputation in the first half of the eighteenth century. He was born in Hildesheim in 1665, and while still a young man showed himself to be a good scholar and possessed of an immense knowledge of books. When a comparatively junior member of the profession he was chosen to be physician to the prince-bishop of Munster, an appointment which he held for many years. Dr. A. Beauvois, the author of the articles in the *Archives*, has made a special study of Cohausen's career and has given the results of his researches to the world in an elaborate biography published in book form in 1900. In August of that same year the *Archives* contained a long account by Dr. Beauvois of Cohausen's treatise on Cinchona, which, he says, has been strangely overlooked by writers on the history and bibliography of that valuable remedy. Cinchona was introduced into Europe in 1640, and medical opinion was still somewhat divided as to its utility when Cohausen wrote in vindication of it a small book with the enigmatical title of "Archeus Febrium Faber et Medicus." A similar fondness for verbal puzzles, sarcastic humour, and quaint turns of fancy is apparent in the titles which he has given to others of his books—such as, for instance, the one written against snuff-taking, the title of which is "Dissertatio Satyrica de Pica Nasi." In the number of the *Archives* for February, 1901, Dr. Beauvois returned to the subject with a lengthy abstract of Cohausen's controversy with Ruysch, the Dutch anatomist, who imagined that he had discovered in the fundus uteri a muscle having the special function of expelling the placenta. Cohausen died in 1750. The list of his works which are in the library of the British Museum occupies an entire page of the catalogue. The book by which he is known to English literature is the "Hermippus Redivivus," a humorous exposition of a scheme for the prolongation of human life to the age of 115 years by inhaling the breath of young women. As one of the means to this end he advises the would-be centenarian to try the effect of becoming a teacher in a girls' school and holding the classes in small unventilated rooms. An English summary of the contents of this work, only two pages in length, appeared in 1743, subjoined to an anonymous volume, entitled, "Dr. Cheyne's Account of Himself and of His Writings," this referring to Dr. George Cheyne, who was born in Aberdeenshire in 1671, practised in London and Bath, and died in 1743. In 1744 John Campbell (born 1708, died 1775) published an English translation of the "Hermippus," which reached its second edition in 1749, and its third in 1771. Boswell says that Samuel Johnson pronounced the volume "very entertaining as an account of the hermetic philosophy and as furnishing a curious history of the extravagances of the human mind." The Rev. S. Baring Gould has devoted to the "Hermippus" one of the chapters of his "Curiosities of Olden Times," published about 1889. In 1885 a reprint of Campbell's translation was published in Edinburgh by Edmund Goldsmid, F.R.H.S.

PLACE OF RESIDENCE FOR A RETIRED SURGEON.

To the Editors of THE LANCET.

SIRS,—Can you or some of your many readers kindly tell a general practitioner who has had 30 years' full work in the eastern counties, where is the best place of residence in England when he retires from work which he intends shortly to do? He is very liable to "catching cold," and suffers slightly from rheumatism and eczema. The locality must, of course, be warm and sunny, yet bracing. His means are limited. If anyone can give him a few hints he will be thankful.

I am, Sirs, yours faithfully,

March 26th, 1901. P. P.

COMMISSIONS AND THE MEDICAL PROFESSION.

THE Preferred Accident Insurance Company of New York, which has opened a branch for the United Kingdom at 74, Cheapside, London, E.C., has sent us some papers calling attention to the business and advantages of the company. We do not venture to express any opinion on the actuarial merits and commercial methods of the Preferred Accident Insurance Company of New York, but we cannot approve the way in which it seeks to entice medical men to become partners and canvassers in its business. It does this in two ways. The company is not content with tempting medical men to insure by "barring the risks of blood-poisoning in a professional operation and without extra premium," but in the event of medical men taking out its policies it purposes to allow a commission of 15 per cent. off the first premium and 10 per cent. off subsequent ones; and for proposals which they "introduce" the company will be pleased to credit them with like commissions. This is a distinct invitation to medical practitioners to become agents in the company's business, and we have

seen in several instances of late years how objectionable such agency is. The company proposes to compile a register of medical men in the various towns and districts of the United Kingdom willing to act as its medical advisers, to examine and to report on every claim under accident and health policies, and invites all and sundry to its service at a uniform fee of half-a-guinea. This fee is not very imposing or very likely to attract many medical men to what is often a very disagreeable and difficult duty. We see great objections to the publication of such a list.

THE SORROWS OF THE PUBLIC VACCINATOR.

A CORRESPONDENT thus describes an experience:—

P.V. (persuasively): Well, Mrs. Jones, am I to vaccinate the baby?

Mrs. J. (indignantly): Oh, but I'm clear on the books, and they take all responsibility (produces her card of subscription to the Anti-Vaccination League).

THE INDISCRIMINATE USE OF ARSENIC FOR AGRICULTURAL PURPOSES.

REFERRING to the report of THE LANCET Analytical Commission on the Scope of Arsenical Contamination Traceable to Impure Sulphuric Acid which appeared in THE LANCET of Jan. 5th, 1901, p. 54, a correspondent (evidently an agriculturist) points out *apropos* arsenic in soils that it is the practice with many farmers to sow white arsenic as a protection from slugs, wire-worms, and birds. The allowance is one pound (7000 grains) per acre. This statement would appear to be quite opposed to the view generally held that plants, especially in the state of germination, are just as sensitive to arsenic as are man and other animals. Our correspondent states that he has seen the men in charge of the drill in a fearful state of inflammation after work from the dry powder dusting their skins. Frequently the emptied packets may be seen blowing from the field on to the highway, some containing a tablespoonful of arsenic, and often whole coveys of partridges are killed. Our correspondent very rightly says that this most dangerous practice ought to be stopped and, further, that there is no necessity for it. We think that this matter might well be brought before the attention of the Royal Commission on Arsenical Poisoning, for, according to our informant, a few inquiries amongst our farm-labourers would lead to some astonishing revelations.

"MÜNCHENER LÖWENBRAU LAGER BEER."

WE regret that owing to an error in calculation, the alcoholic strength of this beer was wrongly represented in our "Analytical Records," published in THE LANCET of March 16th, p. 794. The figures relating to alcohol were based on the specific gravity of the distilled beer being 992, whereas the result obtained was 993. The latter figure gives the following as the alcoholic strength of the beer: alcohol, by weight 3·94 per cent., by volume 4·93 per cent., equal to proof spirit 8·64 per cent. These figures more than ever justify our concluding remark that "the commendable point about Munich beer is that while it is highly nutritious, exceeding in most instances the value in this respect of English beers, it contains a minimum of alcohol."

A QUESTION OF FEES.

To the Editors of THE LANCET.

SIRS,—I was recently attending a patient for an abortion which, she states, was produced by a shock due to a collision whilst riding on a tram-car. I received a letter the other day from the surgeon to the tram-car company stating that he would call at 3.30 the next day to examine the case. I waited on the next day and we saw the case together. On leaving the house he said: "I suppose you will want a fee for this?" I replied, "Certainly, a guinea." "Oh," he said, "the company are not obliged to pay you anything unless they like, but send me in a bill for 10s. 6d. and I will advise the company to pay you." Will you kindly inform me whether I am entitled to a fee and, if so, whether a fee of £1 1s. is a proper fee to charge?

I am, Sirs, yours faithfully,

March 20th, 1901. SPERO.

*** The surgeon to the tramcar company was wrong to this extent, he ignored accepted custom and displayed small *esprit de corps*. When mutual examinations of this sort are arranged by solicitors the injured person's solicitor always arranges for the payment of the medical attendant's fee. Medical men when written to for an appointment should stipulate for the payment of the consultation fee; and it is usually understood that if the patient is examined at the medical attendant's house the fee will be £1 1s., and if at the patient's house, thus entailing a visit, £2 2s. The medical examiner cannot make a proper report without having a history of the case from the medical attendant of the injured person. The alternative would be perhaps to remove dressings or otherwise to interfere with another medical man's treatment, things which are unprofessional and which cannot be done without the patient's consent. The one-guinea and two-guinea fees are not only those usually paid but are moderate. Each consultation may entail letters or visits to arrange the meeting with the patient. The keeping of a fixed appointment is often a difficult matter to a busy medical man. At the interview full description of the case has to be given.—ED. L.

CYCLE PARCEL CARRIERS.

WE have received from the City Manufacturing Co., of 17, Manchester-avenue, Aldersgate-street, E.C., two neat carriers for attaching to the bicycle head which present some decided advantages. The first consists of a net attached to a stout metal hoop provided with a clamp which may be tightened by a screw and nut and fixed upon the pillar of the machine, just beneath the handle-bar. It may be easily attached and its position is not in the least disturbed by vibration when it is properly fixed. The second carrier consists of a framework of light polished metal provided beneath with a Y-shaped strong steel spring clamp. The clamp is forced on to the pillar head where the handle bar forms a T. The inner surfaces of the clamp are fluted so that they may adapt themselves to the pillar-tube easily. Leather straps are fastened to the frame or staging so that small books and parcels or a box of surgical instruments may be safely carried by this means. Nothing is more annoying to cyclists carrying impedimenta than to find during riding that the parcel carriers have become insecure or worse that parcels have been lost through this insecurity. These carriers may be relied on.

"THE PROGRESSIVE MEDICAL ALLIANCE."

To the Editors of THE LANCET.

SIRS,—I note in THE LANCET of March 23rd, p. 907, a letter headed "The Progressive Medical Alliance" in which the writer states: "It is at least a wonder that associations like the Medical Defence Union ..... allow such grave abuses to remain without apparently any efforts to move them." Will you allow me to point out that I brought the circulars of the "Alliance" before the notice of the General Medical Council in October last and that I received a statement from the registrar in December to the effect that the General Medical Council regretted that at the present time no legal action could be taken against the persons concerned. If your correspondent would forward the circular he has received to the President of the General Medical Council it would have the effect probably of stimulating the action that should be taken.

I am, Sirs, yours faithfully,

A. G. BATEMAN.

Medical Defence Union, Trafalgar-square, W.C., March 23rd, 1901.

BRUNTON'S AURISCOPE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 23rd, p. 871, we notice under the heading of "New Inventions" that you make reference to a "Brunton's Auriscope," to which an electric lamp has been adjusted. As regards any novelty in the idea we made a similar apparatus some years ago at the suggestion of Mr. George P. Field, and it is illustrated in our catalogue of 1890, Fig. 4728.—We are, Sirs, yours faithfully,

JOHN WEISS AND SON, LD.

Oxford-street, W., March 23rd, 1901. (H. C. BEDELL.)

Picric.—1. Any vesicles which may be present are punctured. Then a piece of gauze is dipped into a solution of picric acid (the solution may be saturated) and the gauze is squeezed to get rid of superfluous solution and is laid over the part. A little wool may be placed over this and then the dressing is lightly bandaged on. When suppuration is present the dressing will need daily renewal, but if there is no suppuration the dressing need not be changed for four or five days or even more. 2. This question is a little obscure. A Pott's fracture should never need extension and it is very rarely needed in fracture of the lower ends of both bones. If it is desired to apply traction in such a case a stirrup with strapping passing up on each side of the limb to the level of the fracture will be best. 3. A plaster-of-Paris splint may be strengthened at the hip by means of thin strips of metal with their edges turned up like this, ⊔, which are put between the layers of the flannel or other material. A useful size for these strips is as follows: length 9 to 12 inches and width one inch, before the edges are turned. The flat surface should, of course, be turned towards the patient. Strips of wood may also be used.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Liverpool Courier, Warrington Observer Hereford Journal, Wilts Standard, Stirling Observer, Hampstead Express, Sussex Daily News, Eastern Morning News (Hull), Hampshire Advertiser, Blackburn Telegraph, Ilkeston Pioneer, Nelson Chronicle, Norwich Press, York Herald, Walthamstow Express, Western Mai (Cardiff), Malvern News, Manchester Guardian, Scotsman, West Bromwich News, Rugby Advertiser, Hamilton Advertiser, Taunton Express Weymouth Times, Stalybridge Standard, Oxford Times, The South Africa Daily Telegraph, Sanitary Record, Kentish Mercury, Reading Mercury, Mining Journal, Hertfordshire Mercury, Dorset County Chronicle, City Press, Le Courrier de la Presse (Paris), Local Government Chronicle, Surrey Advertiser, Halifax Guardian, Local Government Journal, Ipswich Journal, Ormskirk Advertiser, Fife Journal, Jersey Express, Eckington Express, Boston Independent, Weekly Free Press and Aberdeen Herald, Devon Evening Express, Evening News (Portsmouth), Daily Express (London), Ramsgate Gazette, South Wales News, &c., &c.*

Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (6th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (1st).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-quare, W.).—9 P.M. Dr. J. Mitchell Bruce: Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life. Lecture III.—Prognosis. Treatment. (Lettsomian Lectures.)

TUESDAY (2nd).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Prof. Starling: The Pathology of Dropsy. Dr. Lazarus-Barlow and Dr. Ewart have promised to take part in the discussion.

WEDNESDAY (3rd).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Specimens will be shown by the President (Dr. Horrocks), Dr. C. Lockyer, Dr. H. R. Spencer, and others. Paper:—Dr. E. W. Hey Groves: The Pathology and Treatment of Puerperal Eclampsia with especial reference to the Use of Saline Transfusion, with notes of two cases.

THURSDAY (4th).—NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital).—4 P.M. Clinical Cases and Specimens.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (1st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. M. Morris: Consultation. (Skin.)

TUESDAY (2nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. G. Rankin: Consultation. (Medical.)

WEDNESDAY (3rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Cantlie: Consultation. (Surgical.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Habershon: Cases of Mitral Stenosis.

NORTHERN AND MIDLAND DIVISION OF THE MEDICO-PSYCHOLOGICAL ASSOCIATION (Leicester and Rutland Asylum, Leicester).—4.30 P.M. Mr. R. Stewart: (1) Two Cases of Insanity following Chorea; (2) A Case of Rodent Ulcer treated by X-rays. Discussion on the Improvement of our Methods of Obtaining Information on Matters of Asylum Administration and the Advantages of Establishing a Bureau in connexion therewith (opened by Dr. A. Miller, Hatton Asylum). 7.30 P.M. Dinner at the Grand Hotel, Leicester.

THURSDAY (4th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Consultation. (Surgical.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Mr. B. G. Advani, Homburg; Anderson's College Medical School, Glasgow, Secretary of, Messrs. Armour and Co., Lond.; Mr. C. E. Addison, Colchester; Mr. H. Aitken, Dorrocks; Messrs. Ayrton and Saunders, Liverpool; A. O. W.; Messrs. Adlard and Son, Lond.

B.—Mr. J. W. Barrett, Melbourne; Dr. Byrom Bramwell, Edinburgh; C. Birchall, Ltd., Liverpool; Mr. H. J. T. Blanch, Swindon; Borough Hospital, Birkenhead, House Surgeon of; Burton-on-Trent Infirmary, Secretary of; Messrs. J. Beal and Son, Brighton; Borough of Leicester, Town Clerk of; Bedford County Hospital, Secretary of; Mrs. Boyd, St. Leonards-on-Sea; Dr. J. T. Balmford, Broadbottom; Professor Rubert Boyce, Liverpool; Mr. F. W. Bartlett Romsey; Birmingham, &c., Free Hospital for Sick Children, Secretary of; Mr. T. W. Beasley, Bristol; Borough of Richmond, Town Clerk of; Messrs. C. Barker and Sons, Lond.; Mr. A. A. Bradburne, South Farnborough; Dr. E. M. Brockbank, Manchester.

C.—Mr. J. G. Clegg, Manchester; Dr. Edmund Cautley, Lond.; Dr. Clouston, Edinburgh; Mr. A. E. Clarke, Ashby-de-la-Zouch; College of Preceptors, Lond.; C. J. W.; Clayton House Lond.; Messrs. Condy and Mitchell, Lond.

D.—Dr. J. Gordon Dunlop, South Uist; Lady (Mary) Douglas, Wellington, New Zealand; Dr. F. S. Dennis, New York; Messrs. Duncan, Flockhart, and Co., Edinburgh; Messrs. G. L. Daube and Co., Frankfort; Dover Hospital, Hon. Secretary of; Mr. T. Dixon, Lond.; Dr. W. F. Dearden, Manchester.

Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5s.
Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.
